1 **ABSTRACT**

2 Toll-like receptors (TLRs) trigger immunity by detecting microbe-associated
3 molecular patterns (MAMPs). Flagellin is a unique MAMP since it harbors (i) an
4 antigenic hypervariable region and (ii) a conserved domain involved in TLR5-
5 dependent systemic and mucosal pro-inflammatory and adjuvant activities. Here, the
6 contribution of the flagellin domains in TLR5 activation was investigated. We showed
7 that TLR5 signaling can be neutralized *in vivo* by flagellin-specific antibodies, which
8 target the conserved domain. However, deletions of flagellin's hypervariable region
9 abrogated the protein's intrinsic ability to trigger the production of neutralizing
10 antibodies. The fact that MAMP-specific antibodies block TLR-mediated responses
11 shows that this type of neutralization is a novel mechanism for down-regulating
12 innate immunity. The stimulation of mucosal innate immunity and adjuvancy to
13 foreign antigen was not altered by the hypervariable domain deletions. In contrast,
14 this domain is essential to trigger systemic innate immunity, suggesting that there are
15 distinct mechanisms for TLR5 activation in systemic and mucosal compartments. In
16 summary, specific MAMP determinants control the production of neutralizing
17 antibodies and the compartmentalization of innate responses.

1 INTRODUCTION

2 Toll-like receptors (TLRs) are instrumental in the coordinated induction of
3 innate and adaptive immunity in mammals (1, 2). Since TLRs are expressed by a
4 broad variety of cell types, they are able to trigger immunity throughout the body.
5 Following infection by pathogenic microorganisms, TLRs recognize conserved motifs
6 referred to as microbe-associated molecular patterns (MAMPs) (1). TLR engagement
7 induces a gene expression program dedicated to both innate clearance of and
8 acquired immunity to pathogenic microorganisms (2). For instance, TLRs induce the
9 production of chemokines which, in turn, specifically attract the polymorphonuclear
10 neutrophils (PMNs) directly involved in innate microbial clearance. Furthermore,
11 TLRs promote the secretion of pleiotropic immune mediators (such as $\text{TNF}\alpha$) and the
12 functional maturation of dendritic cells (DCs) which specialize in antigen presentation
13 to lymphocytes. Consequently, TLR agonists not only stimulate “broadly specific” pro-
14 inflammatory immune responses but also enhance the adaptive immune response to
15 defined antigens, and are thus considered to be adjuvants (3). Despite these
16 potentially beneficial effects, the systemic toxicity of MAMPs has prompted efforts to
17 develop derivatives that bias MAMP activity towards adjuvancy (4). Indeed,
18 engineering molecules with unique properties is a major challenge in manipulating
19 immune responses.

20 Bacterial flagellins (the major flagella components in many bacterial pathogens) are
21 specific, unique agonists for TLR5 activation (5, 6). The FliC flagellin from *Salmonella*
22 *enterica* Serovar Typhimurium (*S. Typhimurium*) is the paradigm for studies on
23 flagellum structure-function, immunity and TLR5 signaling (6-9). It is a 494 amino-
24 acid protein with two distinct domains. The amino- and carboxy-terminal conserved
25 regions (comprising about 170 and 90 amino-acids, respectively) form a domain that

1 is essential for TLR5 activation. Furthermore, the motif 89-96 is absolutely required
2 (8-10). The middle (outer) domain of flagellin FliC comprises amino acids from
3 positions 170 to 400 and is not mandatory for TLR5 signaling (9, 10). It is designated
4 as a hypervariable region, since the primary sequences greatly vary in composition
5 and size from one bacterial species to another. In contrast, it is known that the
6 hypervariable region is essential for flagellin antigenicity (11, 12). In fact, flagellins
7 hypervariable region carries H-antigen specificity used for serotyping
8 enteropathogenic bacteria, especially *Salmonella* strains. Deletion of the central
9 domain decreases the flagellins' antigenicity. For example, the *S. Typhimurium*
10 flagellin FliC_{Δ204-292}, which is truncated of 99 amino-acids positioned in middle part of
11 FliC, is poorly recognized by antibodies directed against the whole flagellin (11). The
12 question of whether or not the antigenic and TLR5-activating domains can be
13 functionally dissociated had not been addressed until now.

14 TLR5 agonists are potent activators of systemic and mucosal innate
15 responses. We and others have shown that intravenous (i.v.) injection of flagellins
16 promotes a systemic response, characterized by the production of pro-inflammatory
17 mediators (such as TNF α or IL-6) and DC activation (5, 6, 13-17). Furthermore,
18 flagellins trigger mucosa-specific innate and adaptive defense mechanisms (18-20).
19 For instance, epithelial cell lines and lung mucosa upregulate the production of
20 chemokines like CXCL8 (IL-8) and CCL20 which, in turn, recruit mucosal PMNs and
21 DCs, respectively (18, 19). Various authors have reported that flagellins are potent
22 systemic and mucosal adjuvants that elicit (i) serum and/or secretory antibody
23 responses and (ii) Th1 and Th2 cell responses to both the flagellins themselves and
24 co-administered antigens (14, 17, 21, 22).

1 The goal of the present study was to determine whether or not MAMP
2 domains could alter the outcome of innate and adaptive immune responses. Since
3 MAMPs have adjuvant activity, they also promote intrinsic anti-MAMP responses
4 which, in turn, can neutralize pro-inflammatory and adjuvant properties. We
5 addressed this issue by using flagellin as a model. We found that (i) anti-flagellin
6 antibodies neutralize TLR5 signaling, (ii) deletion of the hypervariable part of flagellin
7 abrogates the latter's ability to induce neutralizing antibodies but does not
8 significantly alter pro-inflammatory and adjuvant activities and (iii) systemic detection
9 of flagellin does not involve the same molecular determinants as mucosal detection.
10

1 MATERIALS AND METHODS

2

3 **Production of recombinant flagellins.** The recombinant flagellins originated from
4 the *Salmonella enterica* Serovar Typhimurium ATCC14028 flagellin FliC (accession
5 number AAL20871). The flagellins FliC and FliC_{Δ205-293} were either isolated from the
6 *S. Typhimurium* strains SIN22 (*fljB*) and SJW46, as described previously (11, 15, 19),
7 or purchased from Alexis Biochemicals (Switzerland). The constructs encoding
8 FliC_{Δ174-400} and FliC_{Δ191-352} were generated by PCR on a pBR322-derived plasmid
9 harboring the wild type *fliC* gene under the control of its own promoter and using the
10 following primer pairs: *AGCACCCattcagcgtatccagacc* / *GCTGGTgctacaaccaccgaaaac*,
11 and *TCGAGatattcctgtaacagttgcagcc* / *ACTCGAGgacggtacatccaaaactgcac* (bases
12 encoding a linker are in italics). Site-directed mutagenesis was also performed on the
13 plasmid harboring FliC_{Δ174-400} in order to replace the residues 89-96 (QRVRELAV)
14 involved in TLR5 detection by the corresponding sequences from a non-signaling
15 flagellin (DTVKVKAT); the resulting protein was thus FliC_{Δ174-400/89-96*} (8). In FliC_{Δ174-}
16 ₄₀₀, FliC_{Δ191-352} and FliC_{Δ174-400/89-96*}, the asparagine located 6 residues from the end
17 was changed into a serine. The truncated flagellins were purified from the
18 supernatant of recombinant *S. Typhimurium* SIN41 (*fliC fljB*), as follows. *Salmonella*
19 were grown in Luria-Bertani (LB) broth for 18 hours at 37°C with agitation. The
20 supernatant was filtered and saturated with 60% ammonium sulfate (Sigma Aldrich,
21 USA). The precipitated materials were recovered by centrifugation, solubilization in
22 20mM Tris/HCl pH7.5 and then dialysis. The proteins were further purified by
23 successive rounds of hydroxyapatite and anion exchange chromatography (Bio-Rad
24 Laboratories, USA). Lastly, the proteins were depleted of lipopolysaccharide (LPS)
25 using a polymyxin B column (Pierce, USA). Using the *Limulus* assay (Associates of

1 Cape Cod Inc., USA), the residual LPS concentration was determined to be less than
2 30 pg LPS per μg recombinant flagellin. When specified, flagellins were treated for 1h
3 at 37°C with 0.017% trypsin-EDTA (Invitrogen, USA) to totally hydrolyze the proteins,
4 followed by heating at 70°C for 1h to inactivate the trypsin. Proteins were analyzed
5 using standard SDS-PAGE and immunoblotting with FliC-specific polyclonal
6 antibodies.

7

8 **Animal experiments.** Female NMRI mice (6-8 weeks old) were purchased from
9 Charles River Laboratories (France) and maintained in a specific pathogen-free
10 facility in an accredited establishment (#A59107; Institut Pasteur de Lille). All
11 experiments complied with current national and institutional regulations and ethical
12 guidelines. For hyper-immunization, animals were injected subcutaneously (s.c.) with
13 the flagellin FliC (1 μg per injection) emulsified in 200 μl of complete Freund's adjuvant
14 (CFA)/PBS on day 1 and incomplete Freund's adjuvant (IFA)/PBS on days 21, 35
15 and 49. On day 63, mice were given 200 μl flagellin/PBS i.v. and were sacrificed 2h
16 later by intraperitoneal (i.p.) injection of 5 mg sodium pentobarbital (CEVA Santé
17 Animale, France) for serum and tissue sampling and analysis.

18 To characterize the mucosal innate response and adjuvant properties, 20 μl of PBS \pm
19 proteins were administered intranasally (i.n.) to mice anesthetized i.p. with 1.5 mg
20 ketamine (Merial, France) and 0.3 mg xylazine (Bayer, Germany) per 25g animal. To
21 study pro-inflammatory responses, mice were sampled either at 2h (for RNA and
22 gene expression assays) or 6h (to test cytokine production). For immunization
23 assays, mice were administered i.n. with PBS \pm LPS-depleted ovalbumin (OVA)
24 (20 μg , Sigma, grade VII, USA) \pm flagellins (1 μg) on days 1 and 21. Broncho-alveolar
25 lavages (BALs) and serum were sampled on day 35.

1 To assess neutralization, immune and mock sera were heated for 30 min at 56°C to
2 inactivate complement. Serial serum dilutions (in 200µl of PBS) were passively
3 transferred to animals by the i.v. route 1h before systemic activation with flagellins. In
4 some experiments, sera were mixed with flagellins diluted in PBS and administered
5 i.n. to test mucosal neutralization.

6 BALs were collected after the intra-tracheal injection of 1ml PBS with Complete
7 Protease Inhibitor Cocktail (Roche, Switzerland) and clarified by centrifugation. Blood
8 samples were collected and clotted at room temperature, with the serum then being
9 separated by centrifugation. Lung protein extracts were prepared by homogenizing
10 tissue with 2 ml T-PER Tissue Protein Extraction Reagent (Pierce, USA)
11 supplemented with protease inhibitors. All samples were stored at -80°C prior to
12 analysis.

13

14

15 **Analysis of antigen-specific antibody responses.** Levels of OVA- or flagellin-
16 specific antibodies in serum and BAL samples were assessed using ELISAs. Briefly,
17 OVA (20µg per well in phosphate buffer 0.2M pH 6.5) and flagellin FliC (100 ng per
18 well in PBS) were coated on MaxiSorp microplates (Nalge Nunc Int., USA) overnight
19 at 4°C. All microplates were washed with PBS/Tween20 0.05% and then blocked
20 with PBS/Dry Milk 1% for 1h at room temperature. Serial dilutions of samples were
21 incubated for 1h at room temperature before development. Biotinylated anti-mouse
22 IgG or IgA antibodies (Southern Biotechnology Associates, USA), HRP-conjugated
23 streptavidin (GE Healthcare, USA) and 3,3',5,5' tetramethylbenzidine (Becton
24 Dickinson Bioscience, USA) were used as development reagents. The reaction was
25 stopped by addition of H₂SO₄ and the OD at 450nm was determined. The IgG titer

1 was defined as the reciprocal of the highest sample dilution yielding an absorbance
2 value of 0.15 OD for OVA and 0.5 OD for FliC and was systematically compared with
3 a reference serum. Titers are given as geometrical means of titers from individual
4 mice. Total IgA and OVA-specific IgA levels in BALs were measured and normalized
5 using a calibration curve with commercial mouse IgA (Sigma). The specific IgA ratio
6 (expressed in ng of OVA-specific IgA per μ g total IgA) was determined for each
7 mouse.

8

9 **Cytokine-specific ELISA and gene expression.** Mouse CXCL2 and CCL20 and
10 human IL-8 (CXCL8) levels were measured in serum, BALs, total lung and/or cell
11 culture supernatant using commercial ELISA kits (R&D Systems, USA).

12 Total RNA from mouse lungs was extracted with the Nucleospin RNA II kit (Macherey
13 Nagel, Germany) and reverse-transcribed with the High-Capacity cDNA Archive Kit
14 (Applied Biosystems, USA). The resulting cDNA was amplified using SYBR Green-
15 based real-time PCR (Applied Biosystems). The specific primers are
16 CGTCATCCATGGCGAACTG / GCTTCTTTGCAGCTCCTTCGT (*ACTB*, coding for
17 β -actin), TTTTGGGATGGAATTGGACAC / TGCAGGTGAAGCCTTCAACC (*CCL20*),
18 and CCCTCAACGGAAGAACCAAA / CACATCAGGTACGATCCAGGC (*CXCL2*).
19 Relative mRNA levels ($2^{-\Delta\Delta C_t}$) were determined by comparing (a) the PCR cycle
20 thresholds (C_t) for the gene of interest and *ACTB* (ΔC_t) and (b) ΔC_t values for treated
21 and control groups ($\Delta\Delta C_t$), as described previously (19).

22

23 **Cell-based assays.** The Caco-2 human colon adenocarcinoma cell line was stably
24 transfected with the plasmid harboring a luciferase gene under the control of the
25 human *CCL20* promoter (23), giving rise to the Caco-Rumbo line. These intestinal

1 epithelial cells were grown in Dulbecco's Modified Eagle's Medium supplemented
2 with 10% fetal calf serum, 10 mM HEPES, non-essential amino acids 1X, penicillin
3 (100 U/ml) and streptomycin (100 U/ml) and (for transgene selection) 0.7 mg/mL
4 G418 (Invitrogen). The human bronchial epithelial cell line BEAS-2B was cultured in
5 Kaigh's F12 nutrient medium supplemented as for Caco-Rumbo medium plus 1 mM
6 sodium pyruvate and insulin-transferrin-selenium mix (Invitrogen).
7 Cells were stimulated with recombinant flagellins for 6h for luciferase assays or for
8 16h before harvesting the supernatant for ELISA. Luciferase activity in cell extracts
9 was measured using the Bright Glo Luciferase Assay (Promega, USA). Relative
10 luminescence (RLU) was normalized as a percentage of the maximum activity with
11 wild type flagellin for the activation test with the recombinant flagellins. For the *in vitro*
12 neutralization test, the RLU was normalized as a percentage of the maximum activity
13 for each protein: $[(RLU_{treated}/RLU_{untreated})/(RLU_{max}/RLU_{untreated})] \times 100$.

14

15 **Statistical analysis.** Statistical differences were analyzed using the Mann-Whitney
16 test and were considered to be significant for p values <0.05 . Unless otherwise
17 specified, results are expressed as arithmetic means \pm standard deviation.

18

19

1 RESULTS

2 Flagellin-specific antibodies neutralize TLR5-mediated signaling

3 Bacterial flagellins are known to elicit strong antibody responses, which are
4 mainly directed against the hypervariable region (11, 12, 24). We hypothesized that
5 anti-flagellin antibodies would neutralize the flagellins' TLR5-stimulating activity.
6 Hence, mice were immunized s.c. with the flagellin FliC or a mock preparation (PBS
7 alone or the irrelevant antigen ovalbumin (OVA) formulated in CFA), followed by
8 boosts with IFA. ELISA analysis revealed that the anti-FliC sera exhibited specific
9 IgG titers $> 10^6$, whereas mock sera titers were below the assay's detection threshold
10 (10^2).

11 We and others have previously used human intestinal epithelial cell lines as
12 unique reporters of flagellin/TLR5-stimulatory activity, based on expression of the
13 chemokine CCL20 (also known as "liver-activated and -regulated chemokine", LARC)
14 (19, 23, 25). Using Caco-Rumbo cells harboring the luciferase gene under the control
15 of the *CCL20* promoter (23), we demonstrated that an anti-FliC serum is able to fully
16 neutralize FliC's TLR5 agonist activity (Fig. 1A). The neutralizing effect of FliC-
17 specific antibodies on TLR5 signaling was then directly assessed in immunized
18 animals. To this end, systemic pro-inflammatory responses in mice (production of
19 CCL20 and CXCL2 chemokines) were studied after i.v. injection of FliC (Fig. 1B-C).
20 In mock-immunized animals, a FliC challenge triggered a significant increase in
21 serum levels of CCL20 and CXCL2, compared with a PBS challenge. In contrast,
22 chemokine production in FliC-immunized animals was not enhanced by any of the
23 challenges. Using passive serum transfer in naive animals, a close correlation was
24 found between the amount of antibody injected and the systemic innate response, as

1 shown in Fig. 1D. In conclusion, pre-existing immunity to flagellin can neutralize the
2 latter's TLR5-stimulating activity, both *in vitro* and *in vivo*.

3

4 **Deletion of flagellin's hypervariable region impairs antigenicity but does not** 5 **modify TLR5-stimulating activity**

6 Since flagellin's antigenic domain (i.e. the hypervariable central region of the
7 molecule) is not mandatory for TLR5 signaling, we sought to engineer flagellin
8 variants which could not be neutralized by antibodies (11, 24). These recombinant
9 molecules were designed on the basis of flagellin's three-dimensional structure and
10 reported immunological properties (7-9). Two novel flagellin molecules (FliC_{Δ191-352}
11 and FliC_{Δ174-400}, composed of 336 and 271 amino-acids, respectively) were
12 constructed by internal deletion (Fig. 2A). As a control, we used the previously
13 characterized variant FliC_{Δ204-292}, which has a partial deletion in the antigenic domain
14 (11) (Fig. 2A). As a negative control for *in vitro* and *in vivo* experiments, mutations
15 that impair TLR5 signaling were introduced into FliC_{Δ174-400}, yielding the recombinant
16 protein FliC_{Δ174-400/89-96*}. The predicted structures of the respective flagellins indicated
17 that the motif 89-96 and the overall structure of the conserved regions were
18 unchanged (Fig. 2A). With the exception of FliC_{Δ204-292}, the variants were unable to
19 complement the motility of flagellin-deficient bacteria and were secreted into the
20 culture supernatant.

21 Next, we assessed the intrinsic antigenicity of the recombinant flagellins. To
22 this end, saturating concentrations of flagellins were coated onto microplates and
23 probed by ELISA, using a hyperimmune serum specific for FliC or FliC_{Δ174-400}. As
24 illustrated in Fig. 2B, we observed 3- to 10-fold lower antibody titers when anti-FliC
25 serum was titrated against FliC variants than against wild type FliC. In contrast, the

1 reactivity of hyperimmune serum specific for FliC_{Δ174-400} was similar, whatever the
2 target flagellin. These results suggest that the central hypervariable region is the
3 major target for anti-flagellin antibodies.

4 Lastly, we sought to establish whether or not the recombinant molecules
5 retained any TLR5-stimulating activity. A dose-response analysis was performed
6 using Caco-Rumbo reporter cells and the lung epithelial cell line BEAS-2B. Activation
7 was assessed by measuring luciferase activity in Caco-Rumbo cells and IL-8
8 secretion by BEAS-2B cells. As shown in Fig. 3A-B, FliC_{Δ204-292}, FliC_{Δ191-352} and
9 FliC_{Δ174-400} were all potent cell activators. The flagellins' respective EC₅₀ values
10 varied slightly with the cell type but fell within the previously described ng/mL range
11 (9). The recombinant flagellins' activity was found to be fully dependent on TLR5,
12 since FliC_{Δ174-400/89-96*} was unable to activate epithelial cells. The requirement for
13 TLR5 signaling was further confirmed by using bone marrow macrophages derived
14 from TLR5-deficient mice. The cells did not synthesize any detectable IL-12 p40
15 (< 18 pg/ml) upon stimulation with 0.5 μg/mL recombinant flagellins in contrast to
16 cells derived from wild type C57BL/6 animals (ranging from 500.7 to 709.5 pg/ml IL-
17 12 p40).

18

19 Deleted flagellins stimulate TLR5-dependent mucosal innate responses

20 TLR5 stimulation by recombinant flagellins was then studied *in vivo* by the
21 mucosal route. To this end, *CCL20* and *CXCL2* expression in the lungs of mice
22 treated i.n. with flagellins was quantified using qRT-PCR (Fig. 3C). Within 2 hours,
23 *CCL20* mRNA pulmonary levels were about 30-fold higher in animals treated with
24 wild type or recombinant flagellins than in mock-treated animals. Furthermore,
25 *CCL20* chemokine production was detected at 6h post-instillation, both in lung

1 homogenates and BALs (Fig. 3D). In control experiments, FliC $_{\Delta 174-400/89-96^*}$ and
2 trypsin-digested flagellins did not induce this type of effect. Similar findings were
3 observed for CXCL2 (data not shown). These results confirmed that the *in vivo* pro-
4 inflammatory response was exclusively due to the recombinant flagellins. Overall,
5 flagellins with deletions in the hypervariable region displayed mucosal pro-
6 inflammatory properties equivalent to those of the wild type FliC counterpart.

7

8 **Recombinant flagellins exhibit mucosal adjuvant activity**

9 Intranasal administration of flagellins is known to promote mucosal adaptive
10 immunity (14, 22, 26). In order to characterize the adjuvant properties of our
11 recombinant molecules, antibody responses in serum and secretions were studied
12 after i.n. immunizations. Ovalbumin (OVA) was used as a model antigen, formulated
13 with or without the various flagellins or with cholera toxin (CT) as a gold standard
14 mucosal adjuvant. The co-administration of FliC with OVA significantly increased the
15 OVA-specific IgG response (both in serum and the BAL, about 300- and 100-fold,
16 respectively), compared with animals immunized with OVA alone (Fig. 4A-B).
17 Moreover, the OVA-specific IgA response was enhanced in BAL, thereby suggesting
18 that FliC promotes the archetypal secretory antibody response of a mucosal adjuvant
19 (Fig. 4C). Interestingly, FliC's effect was similar to that of CT. Like FliC, the
20 recombinant flagellins FliC $_{\Delta 204-292}$, FliC $_{\Delta 191-352}$ and FliC $_{\Delta 174-400}$ were thus able to
21 potentate systemic and mucosal responses. In contrast, FliC $_{\Delta 174-400/89-96^*}$ and trypsin-
22 treated flagellins lacked potency (Fig. 4 and Table 1). Hence, the deletion of
23 flagellin's hypervariable region did not significantly influence the TLR5-mediated
24 mucosal adjuvant properties. Our data also showed that the recombinant molecules'
25 respective effects on innate and adaptive immunity are correlated.

1

2 **Deletion of the hypervariable region impairs the ability to elicit anti-flagellin**
3 **antibodies.**

4 Deletion of the antigenic domain is expected to decrease the flagellin-specific
5 immune response and thereby any neutralization of TLR5-mediated immunity,
6 especially with repeated administration. We therefore decided to assess the efficacy
7 of i.n. immunization with respect to the induction of FliC-specific antibodies. As
8 expected, FliC elicited a strong IgG response in serum and BALs (Fig. 5). In contrast,
9 FliC $_{\Delta 204-292}$ triggered 10-fold lower antibody levels in both fluids than did FliC and a
10 more pronounced effect was observed after immunization with FliC $_{\Delta 191-352}$ and
11 FliC $_{\Delta 174-400}$ to reach non detectable levels as for flagellin treated with protease
12 (Table 1). In conclusion, the flagellins' antigenic and immunostimulatory domains are
13 functionally uncoupled. Therefore, FliC $_{\Delta 191-352}$ and FliC $_{\Delta 174-400}$ are molecules of
14 interest for preventing or attenuating the generation of flagellin-specific antibodies
15 with neutralizing activity.

16

17 **Removal of the hypervariable region does not impair flagellin's susceptibility to**
18 **antibody neutralization.**

19 To determine whether or not FliC $_{\Delta 174-400}$ can escape antibody-mediated
20 neutralization, we performed experiments *in vitro* and *in vivo*. First, we found that an
21 anti-FliC hyperimmune serum is able to neutralize to similar extent the stimulation of
22 epithelial cells by the TLR5 agonists FliC and FliC $_{\Delta 174-400}$ (Fig. 6A-B), indicating that
23 deletion of hypervariable domain does not impair neutralization. We further
24 investigated the capacity of neutralization *in vivo*. The effective doses needed to

1 initiate TLR5-mediated innate responses by the i.n. route was determined. FliC and
2 FliC $_{\Delta 174-400}$ displayed similar dose-response profiles and the 0.1 μ g dose was selected
3 for subsequent neutralization assays (Fig. 6C-D). To this end, animals were hyper-
4 immunized i.n. with FliC to elicit strong, FliC-specific mucosal IgG responses (mean
5 titer \sim 45,000) and then challenged i.n. with 0.1 μ g FliC or FliC $_{\Delta 174-400}$ flagellins. Pro-
6 inflammatory chemokine production in BALs was monitored. Challenge with FliC or
7 FliC $_{\Delta 174-400}$ led to CCL20 production (4.28 ± 1.98 vs 1.08 ± 0.54 ng/ml and 2.48 ± 1.22
8 vs 0.93 ± 0.48 ng/ml in mock- and FliC-immunized mice, respectively) as observed in
9 naïve animals (Fig. 6C-D). Assuming that anti-FliC ELISA titers correlate to
10 neutralizing titers (Fig. 1D), we predicted that the neutralizing activity in BALs was too
11 low to promote blockade of TLR5 signaling in the lungs, whatever the type of
12 flagellin. To definitely define whether neutralization can operate in the lungs,
13 flagellins were incubated with anti-FliC sera prior to administration (Fig. 7). Both
14 TLR5 agonistic activity of FliC and FliC $_{\Delta 174-400}$ were blocked in these conditions. In
15 conclusion, deletion of the flagellin hypervariable region did not enable the resulting
16 molecules to escape from antibody neutralization of TLR5 immune responses. These
17 data also indicated that the FliC neutralization epitopes are located within the
18 conserved sequences 1-173 and 401-494.

19

20 **Mucosal and systemic TLR5-dependent responses depend to different extents** 21 **on the hypervariable flagellin region**

22 We also wanted to study the neutralization by flagellin-specific antibodies of
23 TLR5-dependent responses induced after i.v. injection of the recombinant flagellins.
24 To analyze the systemic activation of innate immunity, the production in circulating
25 pro-inflammatory chemokines CCL20 and CXCL2 was measured by ELISA in serum

1 (Fig. 7). Unexpectedly, we observed that FliC_{Δ174-400} was about 100-fold impaired in
2 its ability to trigger systemic pro-inflammatory effects, compared with the wild type
3 FliC. Whereas 10μg FliC_{Δ174-400} stimulated a slight chemokine production, the variant
4 mutated within the TLR5 motif FliC_{Δ174-400/89-96*} was devoid of activity (0.85 ± 0.27 vs
5 0.02 ± 0.00 ng/ml for CCL20). This contrasted with FliC_{Δ204-292} and FliC_{Δ191-352}, which
6 were both potent activators like FliC (data not shown). Hence, certain molecular
7 determinants on the hypervariable region (or dependent on the latter) are required for
8 systemic TLR5 stimulation but not mucosal TLR5 stimulation. Taken as a whole, our
9 results indicate that TLR5 activation within the mucosal and the systemic
10 compartments is controlled by distinct mechanisms.

11

1 DISCUSSION

2 Over recent years, flagellins have been the focus of many studies on the role
3 of TLR5 in systemic and mucosal immunity (6). In addition to TLR5-dependent
4 stimulatory activity, flagellins display strong antigenic potency. Thus, flagellins are
5 immunodominant antigens in the body's responses to pathogenic bacteria and in
6 chronic inflammatory disorders, since they elicit prominent T-cell and antibody
7 responses (6, 27-29). This dual nature as an innate immunity activator and an
8 antigen means that flagellins are attractive immunological models. It is known that
9 flagellins are constituted by a conserved domain (with a TLR5-activating motif) and a
10 hypervariable region (assigned to antigenicity, especially antibody response) (9, 11,
11 12). Here, we sought to establish whether TLR5 signaling can be regulated by
12 flagellin-specific antibodies and whether TLR5-stimulating and antigenic activities are
13 linked and affect each other. Using truncated forms of the *S. Typhimurium* flagellin
14 FliC and anti-FliC hyperimmune serum, we showed for the first time that pre-existing
15 flagellin-specific antibodies are capable of neutralizing TLR5 signaling effects *in vivo*.
16 Additionally, we demonstrated that deletion of flagellin's hypervariable region
17 promotes escape from neutralization by decreasing the protein's potency for
18 generating antagonistic antibodies. These data support that the flagellin TLR5-
19 stimulating and antigenic domains can be dissociated but that their respective
20 activities can affect the final outcome of immune responses. Lastly, we found that
21 TLR5 signaling is compartmentalized, since the FliC $_{\Delta 174-400}$ flagellin (i.e. lacking the
22 hypervariable region) stimulated immunity in the mucosa but was devoid of any
23 systemic activity.

24 Whereas innate TLR signaling clearly orchestrates adaptive immunity, the
25 reverse process has been little explored. Although recent evidence supports an

1 antigen-independent role for T lymphocytes in the regulation of innate immunity (30),
2 the question of how B cells and, in particular, TLR agonist-specific antibodies
3 influence innate responses has not been resolved. Our study indicates that animals
4 can develop flagellin-specific antibodies that efficiently neutralize the onset of TLR5-
5 mediated responses *in vitro* and *in vivo* (Fig. 1 and 7). Therefore, *in vivo* blockade of
6 TLR signaling by MAMP-specific neutralization antibodies is a novel mechanism for
7 down-regulating innate immunity. Our results are consistent with the report by Saha
8 *et al.*, which suggested that *ex vivo* antibody blockade of the TLR5 activation motif of
9 *Pseudomonas aeruginosa* flagellin reduces its efficacy to induce lung innate
10 responses (31). Interestingly, we found that neutralizing epitopes in *S. Typhimurium*
11 FliC are embedded within the conserved region (1-173 and 401-494) that also carries
12 the activation motif 89-96 (8, 9). We did not perform any cross-neutralization
13 experiments using flagellins isolated from other bacteria: however, if neutralizing
14 antibodies indeed target the conserved TLR5 signaling motif with high affinity, one
15 can expect blockade of the innate responses to any flagellins. We further
16 demonstrated that the mechanisms of action of flagellin-specific antibodies rely on
17 immediate neutralization of TLR5 signaling, since NF- κ B-dependent chemokine gene
18 transcription was not turned on early after challenge (Fig. 3). It is known that LPS can
19 be sequestered by secretory IgA within endosomes in intestinal epithelial cells,
20 thereby blocking TLR4-mediated NF- κ B activation (32). Hence, one can assume that
21 high-affinity flagellin-specific neutralizing antibodies bind to the flagellin signaling
22 motif and thereby prevent any interaction between flagellin and its cognate detector
23 TLR5. Further investigations with flagellin-specific mAbs are needed to dissect the
24 mode of action and the antibodies' targets.

1 TLR signaling neutralization is a major strategy for managing uncontrolled
2 inflammation in sepsis or chronic disease (33). Different targets can promote a TLR
3 signaling blockade, including TLRs themselves and cognate MAMPs. Most efforts
4 seek to block the TLRs and a recent study showed that an anti-TLR4 mAb efficiently
5 inhibited LPS-induced immune responses in acute polymicrobial infections (34). As
6 shown in the present work, MAMP targeting represents an effective and attractive
7 neutralization strategy. Chronic TLR stimulation may contribute to the
8 physiopathology of some diseases and, when conjugated with the intrinsic adjuvant
9 and antigenic activities of MAMPs, it may elicit anti-MAMP neutralizing antibodies. In
10 turn, the neutralization of TLR-specific responses could fully suppress innate
11 responses. Flagellin's hypervariable region is not essential for signaling (Fig. 3 and 4)
12 - a finding which is consistent with the known TLR5 stimulatory activity of *Listeria*
13 *monocytogenes* flagellin, which almost completely lacks a variable region (5). Thus,
14 flagellated bacteria could evade host defenses by facilitating the production of
15 antibodies that reduce the host's ability to mount an innate immune response. The
16 high antigenicity of the flagellin variable domain may be critical in the potentiation of
17 this type of antibody production. Remarkably, the study by Honko *et al.* showed that
18 i.n.-administered anti-flagellin antibodies were unable to interfere with TLR5 (22).
19 Accordingly, we were unable to detect neutralization in similar conditions.

20 In contrast to profilin (that depends on TLR11 for effective antigenicity (35)),
21 flagellin's reduced immunogenicity following hypervariable region deletion does not
22 rely on a TLR5 signaling failure. The deletion of major Th or B epitopes may explain
23 the decreased ability of FliC_{Δ174-400} to elicit antibodies. Previous studies identified a
24 dominant Th epitope in flagellin's conserved domain and highlighted a major role for
25 CD4 T cells in antibody responses (29, 36). Deletion of flagellin's hypervariable

1 region is therefore not absolutely required for effective help for B cell responses.
2 Likewise, i.n. co-administration of FliC $_{\Delta 174-400}$ with OVA (which provides external help)
3 did not enhance anti-FliC antibody titers, compared with instillation of FliC $_{\Delta 174-400}$
4 alone. It seems that deletion of a dominant B cell epitope on the hypervariable region
5 is essential for presentation of a subdominant, neutralizing epitope located within the
6 conserved region.

7 We previously suggested that early epithelial CCL20 production correlates
8 with mucosal adjuvant properties - probably through DC recruitment within the
9 mucosa (19). Our study supports this paradigm, since the mucosal adjuvancy of
10 flagellin molecules correlates with early CCL20 production in lung tissue and BALs
11 (Fig. 3, 6 and 7). TLR5 signaling is absolutely required for flagellin-induced
12 enhancement of immune responses to co-instilled antigens. The deleted flagellin
13 FliC $_{\Delta 174-400}$ also retains adjuvant properties when administered s.c, suggesting that
14 mucosal and dermal responses behave similarly and thus differ from the systemic
15 response (data not shown). Studies with the *S. Typhimurium* flagellin FljB (which
16 harbors a similar deletion in the hypervariable region) have been recently performed
17 with a view to using this type of molecule as an antigen carrier (14, 21). Similar
18 findings were obtained using the deleted flagellin FljB as a carrier for foreign antigens
19 in s.c. immunization (21).

20 The use of wild type flagellin as an adjuvant could lead to harmful effects
21 because production of neutralizing antibodies may attenuate both the booster effect
22 of the adjuvant and the innate responses to pathogenic flagellated bacteria. We
23 established that FliC $_{\Delta 174-400}$ has more prominent beneficial properties, due to its poor
24 capacity to generate neutralizing antibodies. In addition, we found that FliC $_{\Delta 174-400}$ is
25 strongly attenuated for systemic signaling compared with wild type flagellin, whereas

1 mucosal activity was unaffected. This type of effect has been already observed for
2 the TLR4 agonist LPS (4). Recent observations indicated that LPS's molecular
3 features are essential for its biological activity (4, 37, 38). The LPS's O chain
4 composition, the number and the length of the acyl chains and the type of
5 substitutions all affect the outcome of TLR4 signaling. Discrimination relies on a
6 specific combination of co-receptors and adaptor molecules. Indeed the
7 monophosphoryl lipid A is a portion of LPS that preferentially signals through the
8 adaptor TRIF but not MyD88, thereby rendering the molecule less toxic but
9 nevertheless adjuvant (4). Moreover, signaling in the mucosa only has indeed been
10 observed for LPS. For instance, bladder epithelial cells are devoid of the LPS co-
11 receptor CD14 but can detect uropathogenic *Escherichia coli* LPS by using
12 alternative mechanisms involving fimbriae (38). Interestingly, asialo-GM1 has been
13 proposed as a flagellin co-receptor in the lung (39). Lastly, it has been shown that
14 intracellular detectors like IPAF and NAIP5 participate in flagellin detection (40).
15 Whether flagellin-mediated activation operates according to the same mechanisms in
16 both mucosal and systemic compartments remains to be determined.

17 Our findings open up new prospects for the development of antagonistic
18 strategies for manipulating host innate responses and specific inflammatory
19 disorders. Further studies will have to establish whether or not the neutralization of
20 various MAMPs protects or exacerbates bacterial infections or inflammatory
21 diseases.

2

3 **Figure 1. Neutralization of TLR5 signaling by flagellin-specific antibodies.** NMRI
4 mice were immunized s.c. at week 1 with 1µg flagellin FliC and CFA, followed by
5 boosts at weeks 3, 5, 7 with FliC and IFA. In mock conditions, animals were similarly
6 treated with ovalbumin and adjuvants or adjuvants alone. Experiments were carried
7 out at week 9. (A) *In vitro* TLR5-neutralizing activity of flagellin-specific immune
8 serum. Caco-Rumbo epithelial cells harboring the reporter construct *CCL20-luc* were
9 activated for 6h with the flagellin FliC incubated with 50% v/v FliC hyper-immune
10 (open circles) or mock (black circles) sera. Luciferase activity was determined and
11 normalized to the activity obtained with 100 ng/ml FliC. Results are representative of
12 1 of 3 independent experiments. (B, C) *In vivo* TLR5-neutralizing activity of flagellin-
13 specific immune serum. Immunized animals (n=3) were injected i.v. with PBS (black
14 bars) or 0.1 µg (grey bars) or 1 µg of flagellin FliC (open bars). Sera were collected
15 2h later and the concentrations of CCL20 (B) and CXCL2 (C) were determined by
16 ELISA. (D) The neutralizing activity of immune serum. Animals (n=3 per dose) were
17 passively transferred i.v. with various amounts of flagellin-specific or mock serum,
18 and treated 1h later i.v. with recombinant flagellins, as indicated. Chemokine
19 production in serum 2h post-challenge was measured by ELISA. Statistical
20 significance ($p>0.05$) was determined using a Mann-Whitney test.

21

22 **Figure 2. Characteristics and cross-reactivity of hypervariable region-deleted**
23 **flagellins.** (A) A schematic 3D view of the recombinant flagellins. The structure of
24 wild-type flagellin FliC is presented in the left-hand panel using Pymol
25 (<http://www.pymol.org>). In the monomer, terminal regions (1-170 and 400-494) are

1 tightly folded in α -helices and form a structural domain involved in flagellum function.
2 The motif 89-96 (black) is essential for TLR5 signaling. The FliC “hypervariable”
3 domain is mainly constituted of β structures and β turns. Using Swiss-Model
4 (<http://www.expasy.org/spdbv/>), an overall structure was predicted for FliC $_{\Delta 204-292}$ and
5 FliC $_{\Delta 174-400}$, showing partial and total deletion of the hypervariable region,
6 respectively. For FliC $_{\Delta 191-352}$, the positions of amino acids delineating the deletion are
7 shown on the left-hand panel. FliC $_{\Delta 174-400}$ and FliC $_{\Delta 191-352}$ contain GAAG and LELE
8 linkers at the deletion junction, respectively. (B, C) Cross-reactivity of FliC-specific
9 sera. Hyperimmune sera were obtained after s.c. administration of flagellin
10 formulated with CFA for priming, followed by IFA boosts. Serum was titrated in
11 ELISAs for FliC, FliC $_{\Delta 204-292}$, FliC $_{\Delta 191-352}$, and FliC $_{\Delta 174-400}$. The results are
12 representative of 2 experiments. (B) Cross-reactivity of anti-FliC serum. (C) Cross-
13 reactivity of anti- FliC $_{\Delta 174-400}$ serum. Statistical significance ($p > 0.05$ in a Mann-
14 Whitney test) is indicated by an asterisk.

15

16 **Figure 3. Epithelial and mucosal pro-inflammatory activity of hypervariable**
17 **region-deleted flagellins.** (A, B) Activation of epithelial cells by recombinant
18 flagellins. Human epithelial cells were activated with flagellins FliC, FliC $_{\Delta 204-292}$,
19 FliC $_{\Delta 191-352}$, FliC $_{\Delta 174-400}$ or FliC $_{\Delta 174-400/89-96^*}$ at the indicated concentrations. Caco-
20 Rumbo cells harboring the reporter fusion *CCL20-luc* were activated for 6h and
21 luciferase activity was normalized to the maximal activity measured with saturating
22 FliC levels (A). BEAS-2B bronchial epithelial cells were stimulated for 16h before
23 measuring IL-8 levels in the supernatant. Results are representative of 1 of 2
24 independent experiments. (C-D) Stimulation of the mucosal innate response by
25 deleted flagellins. Recombinant flagellins or trypsin-treated preparations (1 μ g

1 equivalent) were administrated i.n. to anesthetized mice (n=3-5). *CCL20*-specific
2 mRNA levels in the whole lungs were determined 2h later using real time qRT-PCR
3 (C). Six hours after instillation, BALs (black bars) and lungs (open bars) were
4 sampled to measure the *CCL20* concentration (D). Statistical significance ($p>0.05$)
5 was determined in a Mann-Whitney test.

6

7 **Figure 4. Adjuvant effect of flagellins with hypervariable region deletion.** Mice
8 (n=8) were immunized i.n. with ovalbumin (OVA) ± flagellins or cholera toxin (CT) on
9 days 1 and 21. On day 35, OVA-specific IgG titers were measured in the serum (A)
10 and BALs (B). The concentration of OVA-specific IgA in BALs was determined (C).
11 Results are representative of 1 of 2 independent experiments. Statistical significance
12 ($p>0.05$) was determined in a Mann-Whitney test.

13

14 **Figure 5. Intrinsic antigenic properties of flagellins lacking a hypervariable**
15 **region.** Mice (n=8) were immunized i.n. with ovalbumin (OVA) ± flagellins or cholera
16 toxin (CT) or LPS on days 1 and 21. On day 35, FliC-specific IgG titers were
17 measured in the serum (A) and BALs (B). Results are representative of 1 of 2
18 independent experiments. Statistical significance ($p>0.05$) was determined in a
19 Mann-Whitney test.

20
