Novel Half-Bridge Inductive DC–DC Isolated Converters for Fuel Cell Applications

Yves Lembeye, Viet Dang Bang, Guillaume Lefèvre, and Jean-Paul Ferrieux

Abstract—This paper proposes a new class of converters based on the inductive input converters for the design of a power electronic interface for fuel cell (FC) applications. After studying the half-bridge structure, two soft-switching dc–dc converters are analyzed: one operating in zero-voltage-switching (ZVS) mode and the other in zero-current-switching (ZCS) mode. The ZVS converter can overcome the drawbacks of the original structure but is more complicated. The ZCS converter cannot operate at duty cycles below 0.5, but is simpler and more suitable for FC applications. Flexible choice of components, low losses, high efficiency, and modular converter possibility are all interesting characteristics of these converters. Their operation principle and characteristics are presented in this paper. Experimental results on 2 kW converters of each structure validate the theoretical analysis.

Index Terms—Fuel cell (FC), isolated dc–dc converter, low losses, zero current switching (ZCS), zero voltage switching (ZVS).

I. INTRODUCTION

THE FUEL CELL (FC) is nowadays well known as an effective generator using hydrogen that is considered as an interesting energy source for the future. An FC produces continuous energy at the output. However, its output characteristics are not linear and depend on the operating point. It is thus necessary to introduce a power electronics interface between this type of generator and the load, so as to stabilize the power supply and improve its efficiency [1], [2]. To ensure the operation in steady state, the interface is composed of a dc–dc converter followed by a dc–ac inverter (Fig. 1). This paper will discuss new dc–dc converters based on the half-bridge inductive converter dedicated to this interface. First, the basic topology is analyzed to introduce the two proposed soft-switching structures: the first one operating in zero-voltage-switching (ZVS) mode and the second in zero-current-switching (ZCS) mode. Both structures exhibit some advantages. The complete description of operation of each converter, as well as its operating condition limits, is presented. This study highlights their advantages and drawbacks. Two prototypes of these two structures validate this theoretical study.

II. HALF-BRIDGE INDUCTIVE DC–DC CONVERTER

The basic half-bridge inductive dc–dc converter (Fig. 2) is obtained from an interleaved boost converter by introducing a transformer and a diode bridge at its output. It indicates many interesting characteristics regarding the constraints imposed by the FC [3]. In fact, the inductive nature and the interleaved technique help to achieve low current ripple with small inductors. The transformer facilitates the boost function and optimizes the choice of switches on the primary side. However, the duty cycle must be greater than 0.5 (as explained in the following section). The leakage inductor of the transformer constitutes the main drawback of this structure. The two proposed structures account for this problem.

The main advantage of the chosen structure concerns the possibility of obtaining high voltage ratio by using not only the boost behavior (gain $\propto 1/(1-\alpha)$, where α is the duty cycle), but also the high-frequency transformer ratio (gain $\propto m$). It should be noticed that input current ripple ($\Delta I \propto 2\alpha - 1$) becomes zero for a duty cycle $\alpha = 0.5$.

A. Operation

Here, we briefly give some elements necessary for the good understanding of the steady-state operation as well as the limits of this converter. To this end, inductors are replaced by current sources and capacitors by voltage sources. The various topologies and the corresponding waveforms are described in Fig. 3.

The MOSFET (V_{MOS1} , I_{MOS1}), input inductance (L_{L1}), and FC (I_{FC}) voltage and current waveforms are represented in Fig. 4.

This structure does not function well for $\alpha \leq 0.5$. Indeed, during the phases where $t \in [\alpha T - T/2, T/2]$ as well as $t \in$

TABLE I
CONSTRAINTS ON SEMICONDUCTORS

MOSFETs	
Maximum current	$I_{Tmax} = \frac{m.I_S}{1-\alpha} + (2\alpha-1)\frac{V_{FC}}{2.L_1.F}$
Average current	$I_{Tav} = \frac{m.I_S}{2.(1-\alpha)}$
RMS current	$I_{Trms} = \frac{m.I_S}{2.(1-\alpha)}\sqrt{3-2\alpha}$
Maximum voltage	$V_{Tmax} = \frac{V_S}{m}$
Output rectifier diodes	
Maximum current	$I_{Dmax} = \frac{I_S}{1-\alpha} + (1-\alpha)\frac{V_{FC}}{2.m.L_1.F}$
Average current	$I_{Dav} = \frac{I_S}{2}$
RMS current	$I_{Drms} = \frac{m.I_S}{2.\sqrt{1-\alpha}}$
Maximum voltage	$V_{Dmax} = V_S$

$[\alpha T, T]$, the topology of the circuit requires that the input inductors should be in series, which is strictly forbidden. As a consequence, the duty cycle will be chosen greater than 0.5 in order to avoid this problem.

B. Characteristics and Constraints

The output voltage expression in continuous conduction mode should be estimated by using the average voltage on the MOSFET switches

$$V_{MOS1-AV} = (1 - \alpha) \frac{V_S}{m} = V_{FC} \Rightarrow V_S = m \frac{V_{FC}}{1 - \alpha}. \quad (1)$$

The input current ripple is reduced with regard to the ripples of each inductor; it will be null for $\alpha = 0.5$

$$I_{FC} = \frac{m I_S}{1 - \alpha} \quad \text{with} \quad \Delta I_{FC} = (2\alpha - 1) \frac{V_{FC}}{L_1 F}. \quad (2)$$

The constraints on the semiconductor components are summarized in Table I.

Output characteristics are plotted in Fig. 5 in continuous conduction mode (CCM). For low-load conditions, a classical phenomenon of discontinuous conduction mode (DCM) occurs, which is similar to that obtained with the single-switch boost chopper. As a result, the output voltage depends on the current and increases for low output currents. At the same time, this phenomenon is amplified by the FC voltage increase. The output voltage (V_S) can be expressed, in reduced coordinates, by

$$y = 1 + \frac{\alpha^2}{2x} \quad (3)$$

Fig. 5. Output characteristics.

Fig. 6. RCD passive clamp.

where x and y represent the output current and output voltage, respectively

$$x = \frac{mL_f I_S}{V_{FC}} \quad (4)$$

$$y = \frac{V_S}{mV_{FC}}. \quad (5)$$

The limit between CCM and DCM is plotted in Fig. 5; the black dots have been obtained by simulation and confirm the theoretical analysis.

Due to the leakage inductance of the transformer, a specific network, active or passive, is required to limit MOSFET over-voltage [4]. Two alternatives are proposed next: the first one dissipative and the second one using energy recovery.

C. Two Variants of the Proposed Converter

- 1) *RCD passive clamp*: The classical RCD network is used for both MOSFET where the resistance is connected to the input source in order to limit the dissipated power (Fig. 6). The main drawback concerns efficiency that is limited by the dissipated energy stored in the leakage inductor.
- 2) *Nondissipative active clamp*: A small buck converter is introduced between the capacitance clamp and the input source (Fig. 7). Thus, the voltage clamp can be controlled by the duty cycle of the additional step-down converter.

This solution provides better efficiency than the earlier topology, but indicates a slight increase in volume [5]. From a func-

Fig. 7. Nondissipative active clamp.

Fig. 8. ZVS half-bridge inductive dc-dc converter.

tional point of view, the operation for duty cycles less than 0.5 becomes possible due to energy recovery, as shown in Fig. 5.

III. SOFT-SWITCHING DC–DC CONVERTERS: DESCRIPTION AND OPERATION ANALYSIS

The half-bridge inductive dc–dc converter obtained from the interleaved boost converter indicates many interesting characteristics relative to the constraints imposed by the FC. However, the leakage inductor of the transformer remains the main drawback of this structure. The following two structures are proposed to deal with these weaknesses [6]–[8].

A. ZVS Half-Bridge Inductive DC–DC Converter

The ZVS structure, presented in Fig. 8, allows the operation with a duty cycle α less than 0.5, and the leakage inductor is used to form the ZVS circuit [6]. Depending on the duty cycle (greater or less than 0.5) and the demagnetization current (total or partial), one of the following four behaviors can occur [9]:

- Case 1: $\alpha > 0.5$ and total demagnetization;
- Case 2: $\alpha > 0.5$ and partial demagnetization;
- Case 3: $\alpha < 0.5$ and total demagnetization;
- Case 4: $\alpha < 0.5$ and partial demagnetization.

We now describe these possible behaviors. In each case, we will consider only the first half period, the second one being identical.

- 1) *Case 1: $\alpha > 0.5$ and Total Demagnetization (Fig. 9):*

Step 1: The voltage on the primary side of the transformer is initially V_{out}/m , and the current in the transformer is positive. This current decreases linearly to zero at βT

$$L_f \frac{dI_{TR}}{dt} = -\frac{V_S}{m}. \quad (6)$$

Fig. 9. Case 1—main waveforms.

Fig. 10. Case 2—main waveforms.

Step 2: When this current reaches zero, diodes D_1 and D_4 do not conduct yet: the diode bridge is blocked. This phase ends with T_2 being switched off.

Step 3: Switch T_4 is on. The voltage on the primary side is imposed by V_{CE} of the capacitor. The current of the transformer becomes negative. The voltage and the current in the primary side of the transformer can be expressed by

$$L_f \frac{di_{TR}}{dt} = -V_{CE} + \frac{V_s}{m} \quad (7)$$

$$V_{TR} = -\frac{V_s}{m}. \quad (8)$$

2) Case 2: $\alpha > 0.5$ and Partial Demagnetization: In this case, the demagnetization of the transformer is partial (Fig. 10).

Step 1: This step happens identically as in case 1. The current of the transformer i_{TR} decreases linearly and continuously but does not reach zero as in case 1.

Fig. 11. Case 3—main waveforms.

Step 2: Switch M_2 is switched off, and i_{TR} is still positive and continues to decrease. The evolution of this current can be expressed by

$$L_f \frac{di_{TR}}{dt} = -\left(V_{CE} + \frac{V_s}{m}\right). \quad (9)$$

Step 3: i_{TR} changes sign. The conduction of D_2 and D_3 leads to the inversion of the transformer voltage. The evolution law of current and voltage during this step is identical to that in case 1.

3) Case 3: $\alpha < 0.5$ and Total Demagnetization (Fig. 11):

Step 1: The current in the transformer is initially zero. Switching T_1 on leads to the decrease of i_{TR} . This current becomes negative

$$L_f \frac{di_{TR}}{dt} = \frac{V_s - mV_{CE}}{m} \quad (10)$$

and

$$V_{TR} = -\frac{V_s}{m}. \quad (11)$$

Step 2: Switching M_1 off leads to switching T_3 on. The short circuit of TR and L_f by the conduction of T_3 and T_4 leads to demagnetization of the transformer until the current reaches zero

$$L_f \frac{di_{TR}}{dt} = \frac{V_s}{m}. \quad (12)$$

4) Case 4: $\alpha < 0.5$ and Partial Demagnetization (Fig. 12):

Step 1: i_{TR} is initially positive. It decreases when M_1 is switched on

$$L_f \frac{di_{TR}}{dt} = -\frac{V_s + mV_{CE}}{m}. \quad (13)$$

Step 2: When demagnetization is complete, i_{TR} becomes negative, and diodes D_2 and D_3 conduct. The voltage of the transformer is reversed and the current can be expressed by

$$L_f \frac{di_{TR}}{dt} = -V_{CE} + \frac{V_s}{m}. \quad (14)$$

Fig. 12. Case 4—main waveforms.

 TABLE II
OUTPUT CHARACTERISTICS

	Output characteristics	Valid field
Case n°1	$y = \frac{1}{x + (1 - \alpha)}$	$y \geq 2$ $\alpha \geq 1/2$
Case n°2	$y = 2 \cdot \sqrt{\frac{2 \cdot x - \alpha}{\alpha - 1}}$	$y \leq 2$ $\alpha \geq 1/2$
Case n°3	$y = \frac{\alpha}{(1 - \alpha) \cdot (\alpha + (1 - \alpha) \cdot x)}$	$y \geq 2 \cdot \alpha / (1 - \alpha)$ $\alpha \leq 1/2$
Case n°4	$y = 2 \cdot \sqrt{\frac{2 \cdot x - \alpha}{\alpha - 1}}$	$y \leq 2 \cdot \alpha / (1 - \alpha)$ $\alpha \leq 1/2$

Output characteristics: To analyze the output characteristics, we use variables x and y defined as

$$y = \frac{V_S}{mV_{FC}} \quad (15)$$

$$x = \frac{mL_f f I_S}{V_{FC}}. \quad (16)$$

The characteristics corresponding to different cases are presented in Table II and Fig. 13.

B. ZCS Half-Bridge Inductive Converter

The ZCS structure (Fig. 14) is obtained from the interleaved boost converter by introducing a transformer and a diode bridge at its output [10]. The leakage inductor of the transformer is used to create the resonance circuit while the capacitor is placed on the secondary side of the transformer. However, for the analysis of the operation, this capacitor is considered as being on the primary side. In addition, the leakage inductor also plays an additional role as that of a soft-switching circuit. On the secondary side, the diode bridge rectifier exhibits low losses due to the weaker current. A drawback of this topology is that the duty cycle must be greater than 0.5. Nevertheless, this is not the case for project specification because of the low input voltage of FC and the requirement of high output voltage.

Fig. 13. Output characteristics.

Fig. 14. ZCS half-bridge inductive dc–dc converter.

One complete switching cycle can be divided into four steps. Each step is briefly described as follows.

1) **Initial Condition:** The circuit is in steady state. T_1 , D_1 , and D_3 are conducting. So

$$i_L = I = \frac{I_{FC}}{2} \quad V_C = \frac{V_S}{m}.$$

Step 1: $t \in [0, t_1]$, T_2 is switched on at 0

$$V_L = L \frac{di_L}{dt} = -\frac{V_S}{m} \Rightarrow i_L = -\frac{V_S}{mL} t + I. \quad (17)$$

This phase finishes when $i_L = 0$ and the diodes on the secondary side are switched off

$$t_1 = \frac{I_{FC}}{2} \frac{mL}{V_S}.$$

Step 2: $t \in [t_1, t_2]$: beginning of the resonance

$$\begin{cases} V_C = \frac{V_S}{m} \cos(\omega_r t) \\ i_L = -\frac{V_S}{mZ} \sin(\omega_r t) \end{cases} \quad (18)$$

with

$$Z = \sqrt{\frac{L}{C}} \quad T_r = 2\pi\sqrt{LC}$$

Switch T_1 is turned off if $i_{T_1} = 0 = I + i_L \Leftrightarrow i_L = -I$. So

$$t_2 = t_1 + \frac{1}{\omega_r} \left[\pi - \arcsin \left(\frac{I_{FC} mZ}{2V_S} \right) \right].$$

Fig. 15. Waveforms in resonant circuit (L - C).

Fig. 16. Output current.

Fig. 17. Switches currents.

Step 3: $t \in [t_2, t_3]$: T_1 is turned off.

The capacitor discharges with a constant current

$$V_C = V_C(t_2) - \frac{I}{C}t. \quad (19)$$

When $V_C = -V_S/m$, diodes D_2 and D_4 begin to conduct

$$t_3 = t_2 + \frac{2C}{I_e} \left[\frac{V_S}{m} \left(1 + \cos \left(\pi - \arcsin \left(\frac{I_{FC} m Z}{2V_S} \right) \right) \right) \right].$$

Step 4: $t \in [t_3, T/2]$: steady state established.

Primary voltage and output current are calculated by

$$V_c = \frac{-V_S}{m} \quad \text{and} \quad I_S = \frac{-I}{m}. \quad (20)$$

At $t = T/2$, T_1 is turned on: it is the start of an opposite cycle.

2) *Voltage and Current Waveforms*: The main current and voltage waveforms are presented in Figs. 15–18. An interesting feature to be noted is that the overcurrent during the commutation is limited to a value near the current in the switched mode. This current is much lower than the overcurrent in a classical resonance-switch converter.

3) *Output Characteristics*: Note that $T_r = 2\pi\sqrt{LC}$ and $T_0 = t_3 - t_1$.

Fig. 18. Switch voltage.

Fig. 19. Output voltage versus switching frequency.

The average output current can be calculated approximately

$$I_S = 2 \frac{I_{FC}}{2m} \frac{(T/2) - T_0}{T} = \frac{I_{FC}}{2m} \left(1 - \frac{2T_0}{T} \right) = \frac{I_{FC}}{2m} \left(1 - \frac{f}{f_r} \right). \quad (21)$$

As for voltage, by applying power conservation

$$V_S \cdot I_S = V_{FC} \cdot I_{FC} \Rightarrow \frac{V_S}{m V_{FC}} = \frac{2}{1 - (f/f_r)}$$

$$\text{with} \quad f_r = \frac{1}{2\pi\sqrt{LC}}.$$

The output voltage characteristic is illustrated in Fig. 19. This figure is reminiscent of the output characteristic of the hard-switching converter, by replacing the duty cycle by the ratio f/f_r . Thus, the output voltage can be controlled by only adjusting the ratio between the switching frequency f and the resonance frequency f_r . In addition, as the switching frequency is variable, it might create the risk of parasite resonance due to L and C_{oss} from the MOSFET.

4) *Essential Relations and Constraints (Table III)*: As the leakage inductor is used as a resonance inductor, the resonance capacitor must be placed on the secondary side.

IV. EXPERIMENTAL RESULTS

Two converters were built corresponding to the two structures presented so as to validate the earlier analysis.

TABLE III
SEMICONDUCTORS AND CAPACITOR CONSTRAINTS

T_1 and T_2	Output diodes

 Fig. 20. MOSFET current and voltage ($P = 2$ kW, $\alpha > 0.5$).

A. ZVS Half-Bridge Inductive Converter

A 2-kW prototype is designed according to Table I. The output voltage is controlled to 370 V and switching frequency is 50 kHz.

References and characteristics of the main components are listed in Table IV.

The main waveforms are shown in Figs. 20 and 21; efficiency at nominal load is 95.8%.

B. ZCS Half-Bridge Inductive Converter

A 2-kW prototype of ZCS converter has been built. The output voltage is controlled at 350 V. Main characteristics of passive components are given in Table V.

An overvoltage of about 50 V can be noticed during turn-off time. This phenomenon is due to capacitor C_{OSS} of the MOSFET and the resonance inductor. Consequently, a clamped-voltage RCD circuit is introduced. Fig. 22 shows the effect of this clamp on voltage v_T that is primary transformer voltage when resonant capacitor is placed on the secondary side of the transformer. The overcurrent can also be explained by the recov-

ery phenomenon of the MOSFET diode. This can be reduced by using MOSFETs with better body diode. The measured efficiency is 96%.

V. CONCLUSION

In this paper, after a review of well-suited dc–dc converter for FC applications, we have developed two soft-switching dc–dc converters based on the half-bridge inductive converter. The ZVS converter overcomes the duty cycle limit of the original structure and avoids the effects from the leakage inductor by using it in the resonance circuit. The ZCS converter uses

Fig. 23. Compared efficiency of the three converters. Output power (in kilowatts).

the transformer leakage inductor to create the resonance circuit, but still cannot operate at duty cycle below 0.5. However, it is suitable for FC applications because its output voltage is relatively high in comparison with the FC voltage. Moreover, the structure is simple and uses less components. Low losses are incurred in the semiconductors because the controlled semiconductors (MOSFET) are used only on the primary side (low voltage side) and diodes are used on the high voltage side. Soft switching reduces switching losses. A high ratio between output and FC voltages is obtained while ensuring a high efficiency: modularity is thus possible. The efficiency was compared between the three structures at nominal power (Fig. 23). First, the efficiency in ZVS mode remains lower than that of the basic structure because of the conduction losses. In addition, ZCS mode exhibits a slightly better efficiency at full power.
