SUMMARY - *Toward an European humus forms reference base* - A network of European humus researchers was founded in Trento (Italy) in 2003. The aim of the Group's work was to prepare a synthesis of the knowledge about humus forms which could be used as a field key for classifying and interpreting humus forms within an ecological framework. Stages: first European classification of terrestrial humus forms, prepared in Vienna (Austria, 2004) from a French plan, presented at EUROSOIL 2004 in Freiburg (Germany, 2004); new form (Amphi) admitted as main humus form (Italy, 2005); first European classification of semi-terrestrial humus forms, from a Dutch pattern (Italy, 2005); poster at the 18th Congress of Soil Science (USA, Philadelphia, 2006); enlargement of the Amphi category towards some Mediterranean humus forms (Italy, 2007); definitive agreement for a complete classification key, EUROSOIL (Austria, 2008). Protocols for assessment and sampling of organic and organo-mineral layers were set up, as well as definitions for specific horizons. After six years of exchanges among specialists from 12 European countries, the outcome of this European set-up is briefly presented here as a succession of figures.

RIASSUNTO – *Verso una base di riferimento per le forme di humus Europee* – Un gruppo europeo di ricercatori sull'humus nacque a Trento (Italia) nel 2003. Tale fondazione si propose di realizzare una sintesi delle conoscenze sulle forme di humus che potesse essere usata in campo come chiave di classificazione e di interpretazione di tali forme su basi ecologiche. Tappe del processo: prima classificazione europea delle forme di humus terrestri, preparata a Vienna (Austria, 2004) a partire da uno schema francese, presentata all'EUROSOIL 2004 di Friburgo (Germania, 2004); ammissione di una nuova forma (Amphi) tra le unità di primo livello (Italia, 2005); prima classificazione europea delle forme di humus semi-terrestri, a partire da uno schema Olandese (Italia, 2005); poster al 18esimo Congresso della Scienza del Suolo (USA,

Studi Trent. Sci. Nat., 85 (2009): 145-151. © Museo tridentino di Scienze Naturali, Trento, 2009. ISSN 2035-7699.

Philadelphia, 2006); allargamento della forma Amphi verso alcune forme mediterranee (Italia, 2007); definitivo consenso per una chiave di classificazione completa, EUROSOIL (Austria, 2008). I protocolli di riconoscimento e campionamento degli orizzonti organici e organo-minerali sono stati redatti insieme alle definizioni riguardanti alcuni orizzonti più specifici. Dopo sei anni di scambi tra specialisti di 12 Paesi europei, l'essenza di tale lavoro di sintesi viene qui di seguito illustrada in una successione di figure.

Key words: humus, humus classification, humus form, European Humus Group

Parole chiave: humus, classificazione di humus, forma di humus, Gruppo di Humus Europeo

1. HISTORICAL PATH

A network of European researchers working on humus forms was created in Trento (Italy) in 2003. In July 2004, the commission "Classification of (European) Humus Forms" met in Vienna (Austria) and drafted a taxonomic key to the main terrestrial humus forms based on response to environmental conditions and specific biological activities (Ponge 2003; Graefe & Beylich 2003). This draft was presented in Freiburg (Germany) at the EUROSOIL 2004 congress (Jabiol *et al*. 2004).

From this event onwards, other results have been achieved:

- the definitive admission of the *Amphi* forms at the first level of the classification during the meeting in San Vito (University of Padua, Italy, 2005). The name means "*twin* forms", differentiating from Moder because of the strong earthworm activity in the A horizon and from Mull, on the other side, because of the important accumulation of organic matter at the soil surface. The same solution has been adopted in the last version of the French Référentiel Pédologique (Baize et al. 2009);
- a draft of a European key of classification has been presented in the form of a poster (Fig. 1) at the 18th Congress of Soil Science, USA, Philadelphia (Zanella *et al.* 2006);
- the first level of the proposed classification key has been implemented and integrated into the manual of the UN-ECE–ICP Forests programme available on Internet (http://www.icp-forests.org/Manual.htm);
- an agreement has been reached for characterizing the structure of the A horizon within the European humus forms classification. The soil structure defined in the USDA Soil Survey Manual (1993), also used in the World Reference Base for Soil Resources (IUSS Working Group WRB 2006) and the FAO Guidelines 2006, has been adopted in the new characterization of the five diagnostic A horizons;
- a workshop was made to improve and extend the *Amphi* classification draft in order to include some typical Mediterranean humus forms (meeting at the University of Cagliari, Italy, 2007);

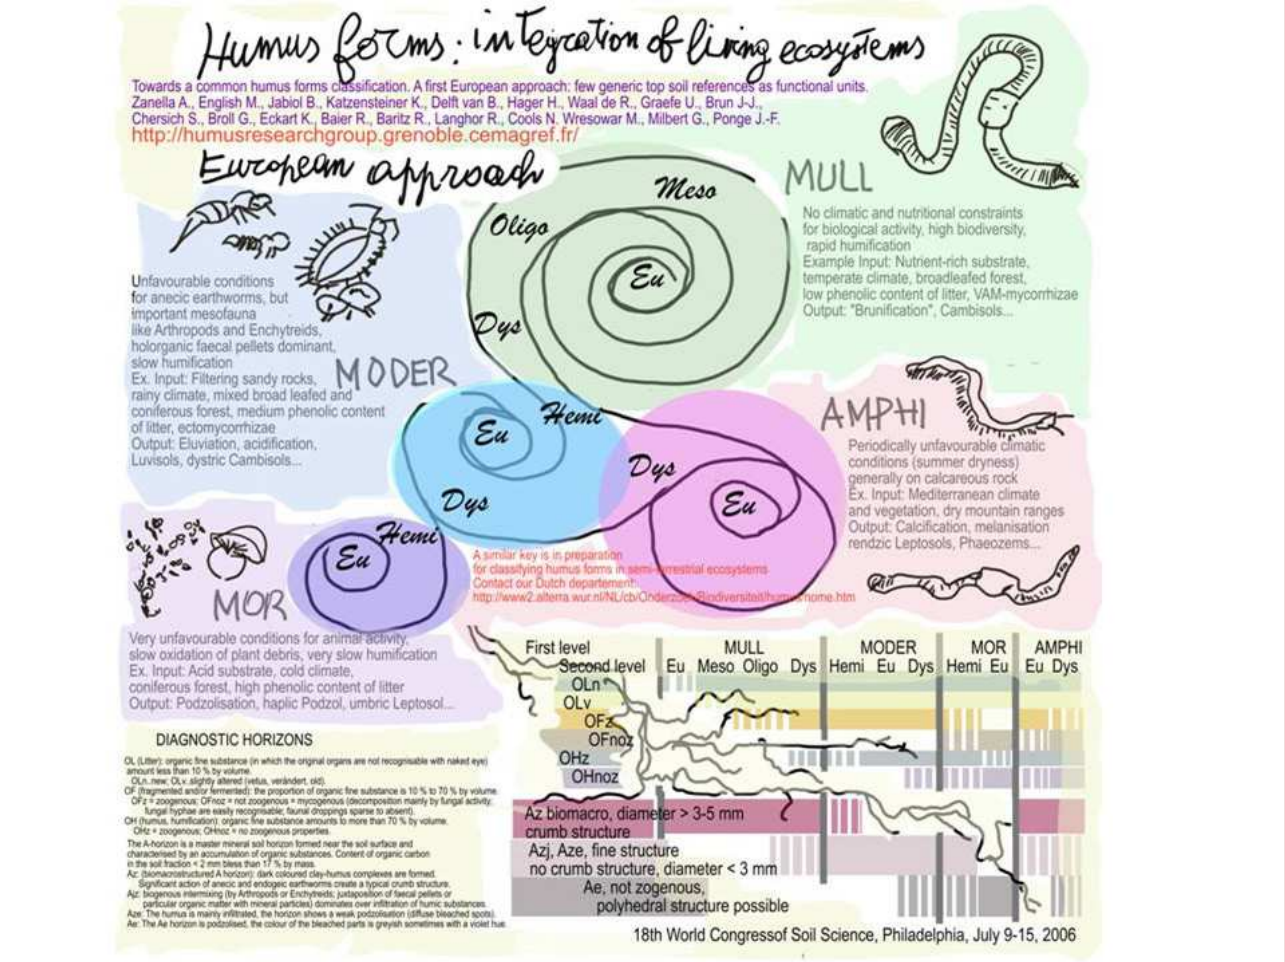

Figure 1. A poster at the World Congress of Soil Science in Philadelphia (2006), for disseminating the humus forms concept. It resumes the work about the humus forms two years after the foundation of the European Humus Group: 4 main humus forms, 11 second-level categories and a mild attempt to organize some ecological attractors around them.

- the most recent version of the key, re-elaborated thanks to a workshop organized during the EUROSOIL 2008 congress (Vienna, Austria), includes the *Tangel* humus form, which has a relatively broad distribution in the calcareous Alpine ecosystems;
- starting from a first attempt presented by the Dutch members of the humus group (Alterra) during a meeting in San Vito (Italy, 2005), the *semi-terrestrial* humus forms have been considered and included in the classification. A final agreement was found only after the Eurosoil 2008 meeting (Fig. 2). Diagnostic horizons for the first and second-level references have been established, and new *Histo* forms have been placed in synoptic tables (Fig. 3);
- with the aim to complete the humus classification panel, definitions for Hydro, Litho, Peyro, Psammo, Rhizo and Ligno forms were recently established exchanging a sharable draft (Figs 4-7).

2. THE EUROPEAN HUMUS FORMS CLASSIFICATION

The first general principles of a European classification of terrestrial haplic forms have now been finalized (Figs 8, 9). Protocols for the assessment and sampling of organic and organo-mineral horizons are set up as well as definitions of the different kinds of organic and mineral horizons and their designation. The *recognizable remains* are separated from *humic* and *mineral components.* In fact, the Babel (1980) definition of "fine organic matter", used in other systems of humus forms classification, did not work in an efficient way in order to describe the organic horizons with an appreciable content of large organo-mineral large structures (earthworm faeces). The definitions of *zoogenic* and *non zoogenic materials* allow to better differentiate between some key diagnostic horizons, improving the field estimate of the part of the organic matter degraded by fungi. Concerning Histo forms, *fibric* and *sapric components* of the horizons were defined.

The Humus Group considers the key of the humus forms classification as its common endeavour, a contribution to the understanding of ecosystem functioning (Fig. 10) and of nutrients cycling, and may introduce humus forms classification as a diagnostic tool for assessing the ecosystem health

status. The Humus Group sees the description and the study of humus forms as a tool to characterize ecosystems or biotic communities, which evolve together in response to environmental factors, and humus forms may be indicative for these (Ponge 2003). We see the very abstract and simplistic procedure of humus forms classification as our common and demanding task, which makes sense only within a functional approach. An effort was done for translating field data (Sartori *et al.* 2004) and present knowledge (humus forms structure and ecology) in graphical models or tables allowing to use these concepts in ecological procedures. Groups of animals were associated to diagnostic horizons and humus forms (Fig. 11).

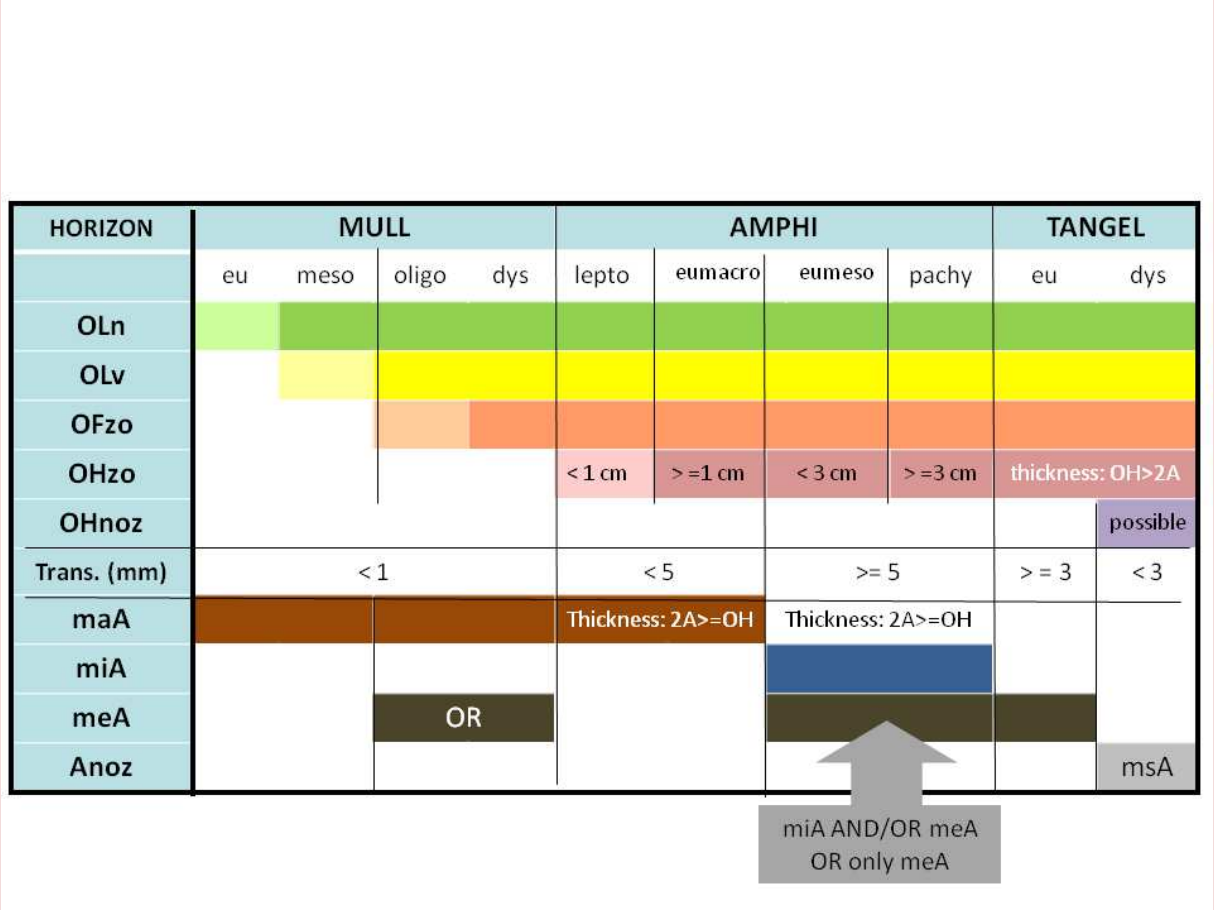

Figure 8. Terroforms on calcareous or lithologically mixed substrates. OL, OF, OH = organic horizons; n = new litter; v = old litter; A = organo-mineral horizon; zo = zoogenous; noz = non zoogenous; ma = biomacrostructured; me = biomesostructured; mi = biomicrostructured; Trans. (mm) = transition between organic and organo-mineral horizons (millimeters).

3. ISSUE

The publication is perceived by the Humus Group as a forum which allows us to introduce the wider scientific community to our work and to further our efforts towards an internationally agreed classification and standardization of defined humus forms. To achieve these goals the paper is organized as following:

- introduction and general synoptic tables of humus forms classification;
- terro forms and Histo forms classification;
- vocabulary, definition of main horizons, synoptic tables for field classification. A biological point of view is also given for linking bio-degraders and structure of the main diagnostic horizons;
- functional aspects;
- practical value of the delivered classification.
