## Abstract

We present a version of system  $F_\omega$ , called  $F_\omega^C$ , in which the layer of type constructors is essentially the traditional one of  $F_\omega$ , whereas provability of types is classical. The proof-term calculus accounting for the classical reasoning is a variant of Barbanera and Berardi's symmetric  $\lambda$ -calculus.

We prove that the whole calculus is strongly normalising. For the layer of type constructors, we use Tait and Girard's reducibility method combined with orthogonality techniques. For the (classical) layer of terms, we use Barbanera and Berardi's method based on a symmetric notion of reducibility candidate. We prove that orthogonality does not capture the fixpoint construction of symmetric candidates.

We establish the consistency of  $F_\omega^C$ , and relate the calculus to the traditional system  $F_\omega$ , also when the latter is extended with axioms for classical logic.

## 1 Introduction

Approaches to a Curry-Howard correspondence for classical logic seem to converge towards the idea of programs equipped with some notion of control [Par92, BB96, Urb00, Sel01, CH00]. The general notion of reduction/computation is non-confluent but there are possible ways to restrict reductions and thus recover confluence.<sup>1</sup>

It is then tempting to try and build, on such a correspondence for classical logic, powerful type theories, such as those developed in intuitionistic logic (Pure Type Systems [Bar91, Bar92], Martin-Löf type theories [ML84]). Approaches to this task (in natural deduction) can be found in [Ste00], in a framework *à la* Martin-Löf, and in [BHS97] (but with a confluent restriction of the reductions of classical logic).

---

<sup>1</sup>Two such canonical ways are related to CBV and CBN, with associated semantics given by CPS-translations, which correspond to the usual encodings of classical logic into intuitionistic logic known as “not-not”-translations.

Intuitionistic type theories, however, exploit the fact that predicates are pure functions, which, when fully applied, give rise to formulae with logical meanings. The Curry-Howard correspondence in intuitionistic logic can then describe these pure functions as the inhabitants of implicative types in a higher type layer (often called the layer of kinds).

On the other hand, inhabitants of implicative types in classical logic can be much wilder than pure functions (owing to the aforementioned notion of control), so it is not clear what meaning could be given to those simili-predicates, built from classical inhabitants of implicative types, and whose reductions may not even be confluent. However, such an issue is problematic only in the layer of types, a.k.a the *upper layer*, which various type theories “cleanly” separate from the layer of terms, a.k.a the *lower layer*.

This paper, which extends [LM06], shows that it is perfectly safe to have cohabiting layers with different logics, provided that the layer of types is free from any dependency on terms, i.e. that the system has no dependent types. For that we chose to tackle System  $F_\omega$  [Gir72]. We present here a version of it called  $F_\omega^C$  that is classical in the following sense:

The upper layer is purely functional, i.e. intuitionistic: it is in fact the lambda-calculus extended with constants for logical connectives. Then, for those objects of the layer that are *types* (a.k.a. *formulae*), we have a notion of provability with proof derivations and proof-terms in the lower layer, which is here classical instead of intuitionistic.

The motivation for the choice of tackling  $F_\omega$  is threefold:

- System  $F_\omega$  is indeed the most powerful corner of Barendregt’s Cube without dependent types [Bar91, Bar92].
- System  $F$  and the simply-typed  $\lambda$ -calculus also cleanly separate the lower layer from the upper layer, but the latter is trivial as no computation happens there, in contrast to System  $F_\omega$  which features computation in both layers, both strongly normalising.
- The version  $F_\omega^C$  with a classical lower layer, in contrast to the intuitionistic one, features two *different* notions of computation (one intuitionistic and confluent, the other one classical and non-confluent), also both strongly normalising. Hence,  $F_\omega^C$  represents an excellent opportunity to express and compare two techniques to prove strong normalisation that are based on the method of reducibility of Tait and Girard [Gir72] and that look very similar, and solve a conjecture raised in [LM06] about one technique not capturing the other.

The strong normalisation of the upper layer (section 3.1) represents an opportunity to rephrase the reducibility method [Gir72] with the concepts and terminology of *orthogonality*, which provides a high level of abstraction and potential for modularity, but has a sparse literature (which includes [MV05]).

The technique for the strong normalisation of the lower layer (section 3.2) adapts Barbanera and Berardi’s method based on a symmetric notion of reducibility candidate [BB96] and a fixpoint construction. Previous works (e.g.

[Pol04, DGLL05]) adapt it to prove the strong normalisation of various sequent calculi, but (to our knowledge) not pushing it to such a typing system as that of  $F_\omega^C$  (with a notion of computation on types). Note that we also introduce the notion of orthogonality in the proof technique (to elegantly express it and compare it to the proof for the upper layer).

The method works in fact without any surprise. Difficulties would come with dependent types (the only feature of Barendregt’s Cube missing here), precisely because they would pollute the layer of types with non-confluence and unclear semantics.

The main purpose of presenting together the two proof techniques described above is in fact to express them whilst pointing out similarities, and to examine whether or not the concepts of the symmetric candidates method can be captured by the concept of orthogonality. In this paper we solve the conjecture of [LM06] by proving that it cannot.

Finally we prove the consistency of  $F_\omega^C$ , and establish a formal connection with the traditional system  $F_\omega$ , also when the latter uses extra axioms to allow classical reasoning.

Section 2 introduces  $F_\omega^C$ . Section 3 establishes the strong normalisation of the layer of types, and that of the layer of terms. Section 4 compares the two proofs and solves the conjecture of [LM06]. Section 5 establishes some logical properties of  $F_\omega$  such as consistency.

## 2 Syntax, Reduction and Typing of $F_\omega^C$

### 2.1 Syntax

$F_\omega^C$  distinguishes four syntactic categories: *kinds*, *type constructors* (or *constructors* for short), *terms* and *programs*:

<b>Kinds</b>	$K, K' ::= \star \mid K \rightarrow K'$
<b>Constructors</b>	$A, B, C, \dots ::= \alpha \mid \alpha^\perp \mid \lambda\alpha : K . B \mid B A$ $\mid A \wedge B \mid A \vee B$ $\mid \forall\alpha : K . B \mid \exists\alpha : K . B$
<b>Terms</b>	$t, u, v, \dots ::= x \mid \mu x^A . p$ $\mid \langle t, u \rangle \mid \lambda x^A y^B . c$ $\mid \Lambda\alpha : K . t \mid \langle A, t \rangle$
<b>Programs</b>	$p ::= \{t \mid u\}$

*Kinds*, that are exactly the same as in system  $F_\omega$  [Gir72, BG01], are a system of simple types for type constructors. (We use the word ‘kind’ to distinguish kinds from the types which appear at the level of type constructors.) The basic kind  $\star$  is the kind of *types*, that is, the kind of all type constructors that represent types of terms—or *propositions/formulae* through the Curry-Howard correspondence.

*Type constructors*, often shortened as *constructors*, are basically simply-typed  $\lambda$ -terms with two binary operators  $A \wedge B$  (conjunction),  $A \vee B$  (dis-

junction) and two extra binders  $\forall\alpha : K . A$  and  $\exists\alpha : K . A$  to represent universal and existential quantification. (There is no primitive implication in the system.)

As in linear logic [Gir87], *negation*  $\alpha \mapsto \alpha^\perp$  is only primitive on variables, but the extension as an involution  $A \mapsto A^\perp$  on all type constructors is defined via de Morgan laws:

$$\begin{array}{ll}
(\alpha)^\perp = \alpha^\perp & (\alpha^\perp)^\perp = \alpha \\
(A \wedge B)^\perp = A^\perp \vee B^\perp & (A \vee B)^\perp = A^\perp \wedge B^\perp \\
(\forall\alpha : K . B)^\perp = \exists\alpha : K . B^\perp & (\exists\alpha : K . B)^\perp = \forall\alpha : K . B^\perp \\
(\lambda\alpha : K . B)^\perp = \lambda\alpha : K . B^\perp & (B A)^\perp = B^\perp A
\end{array}$$

Notice how negation propagates through  $\lambda$ -abstraction and application. In our calculus, the notation  $A^\perp$  is not only meaningful for types (that is, constructors of kind  $\star$ ), but it is defined for all type constructors.

With negation extended to all type constructors we can define implication  $A \Rightarrow B$  as  $(A^\perp) \vee B$ .

However, one must take care in the way constructor variables are bound. In what follows, we assume that the constructions  $\forall\alpha : K . B$ ,  $\exists\alpha : K . B$  and  $\lambda\alpha : K . B$  bind all free occurrences of the variable  $\alpha$  in  $B$ , including those which correspond to a subterm of the form  $\alpha^\perp$ . (In other words, the syntactic construction  $\alpha^\perp$  is not a variable.) For instance, the type constructor

$$\neg = \lambda\alpha : \star . \alpha^\perp$$

is closed; this is the type constructor which represents negation as a function (of kind  $\star \rightarrow \star$ ). The computation rules of negation are incorporated into the calculus by extending the definition of the (external) operation of substitution written  $B\{\alpha \setminus A\}$  to the case where  $B$  is a negated variable, as shown in Fig. 1.

---

---

$$\begin{array}{ll}
(\lambda\alpha : K . A)\{\beta \setminus C\} & = \lambda\alpha : K . A\{\beta \setminus C\} \\
\alpha\{\beta \setminus C\} & = \alpha \quad (\text{if } \beta \neq \alpha) \\
\beta\{\beta \setminus C\} & = C \\
\alpha^\perp\{\beta \setminus C\} & = \alpha^\perp \quad (\text{if } \beta \neq \alpha) \\
\beta^\perp\{\beta \setminus C\} & = C^\perp \\
(A \wedge B)\{\beta \setminus C\} & = A\{\beta \setminus C\} \wedge B\{\beta \setminus C\} \\
(A \vee B)\{\beta \setminus C\} & = A\{\beta \setminus C\} \vee B\{\beta \setminus C\} \\
(\forall\alpha : K . A)\{\beta \setminus C\} & = \forall\alpha : K . A\{\beta \setminus C\} \\
(\exists\alpha : K . A)\{\beta \setminus C\} & = \exists\alpha : K . A\{\beta \setminus C\}
\end{array}$$

---

---

Figure 1: Substitution in the upper layer

This (extended) notion of substitution satisfies the following properties:

**Remark 1**

1.  $(A\{\alpha\backslash B\})^\perp = A^\perp\{\alpha\backslash B\}$ .
2.  $A\{\alpha\backslash B\}\{\beta\backslash C\} = A\{\beta\backslash C\}\{\alpha\backslash B\{\beta\backslash C\}\}$

The (proof-)terms of our calculus are basically the terms of Barbanera and Berardi's symmetric  $\lambda$ -calculus, with the difference that connectives are treated multiplicatively. In particular, disjunction is treated as a negative connective whose proofs are built using a double binder written  $\lambda x^A y^B . p$ . On the other hand, proofs of conjunction are introduced as usual, using the pairing construct written  $\langle t, u \rangle$ .

Finally, programs are built by making two terms  $t$  and  $u$  interact using a construction written  $\{t \mid u\}$ , where each term can be understood as the evaluation context of the other term. We assume that this construction is symmetric, that is, that  $\{t \mid u\}$  and  $\{u \mid t\}$  denote the same program. Henceforth, terms and programs are considered up to this equality together with  $\alpha$ -conversion.

## 2.2 Reduction and Typing for Types

The reduction relation on the layer of type constructors is  $\beta$ -reduction, which is defined as usual as the contextual closure of the relation

$$(\lambda\alpha : K . B)A \longrightarrow_\beta B\{\alpha\backslash A\}.$$

However, the extension of the definition of substitution to negated variables mechanically enhances  $\beta$ -reduction in such a way that we get de Morgan equalities for free:

$$\begin{aligned} \neg(A \wedge B) &=_\beta \neg A \vee \neg B & \neg(A \vee B) &=_\beta \neg A \wedge \neg B \\ \neg(\forall\alpha : K . B) &=_\beta \exists\alpha : K . \neg B & \neg(\exists\alpha : K . B) &=_\beta \forall\alpha : K . \neg B \end{aligned}$$

(Here,  $\neg$  denotes the type constructor  $\lambda\alpha : \star . \alpha^\perp$ , and  $=_\beta$  denotes the symmetric transitive and reflexive closure of  $\longrightarrow_\beta$ .)

**Proposition 2** — *The (enhanced)  $\beta$ -reduction on type constructors is confluent.*

**Proof:** This is proved by introducing the corresponding notion of parallel reduction, following Tait and Martin-Löf [Bar84].  $\square$

---

---

$\frac{}{\Sigma \vdash \alpha : K} (\alpha : K) \in \Sigma$	$\frac{}{\Sigma \vdash \alpha^\perp : K} (\alpha : K) \in \Sigma$
$\frac{\Sigma, \alpha : K \vdash B : K'}{\Sigma \vdash \lambda \alpha : K . B : K \rightarrow K'}$	$\frac{\Sigma \vdash B : K \rightarrow K' \quad \Sigma \vdash A : K}{\Sigma \vdash B A : K'}$
$\frac{\Sigma \vdash A : \star \quad \Sigma \vdash B : \star}{\Sigma \vdash A \wedge B : \star}$	$\frac{\Sigma \vdash A : \star \quad \Sigma \vdash B : \star}{\Sigma \vdash A \vee B : \star}$
$\frac{\Sigma, \alpha : K \vdash B : \star}{\Sigma \vdash \forall \alpha : K . B : \star}$	$\frac{\Sigma, \alpha : K \vdash B : \star}{\Sigma \vdash \exists \alpha : K . B : \star}$

---

---

Figure 2: Typing rules for type constructors

Typing contexts for variables of type constructors, that we call *signatures*, are (unordered) lists of declarations of the form  $(\alpha : K)$ :

**Signatures**  $\Sigma ::= \alpha_1 : K_1, \dots, \alpha_n : K_n$

The inference rules of the typing judgement  $\Sigma \vdash A : K$  ('In the signature  $\Sigma$ ,  $A$  is a constructor of kind  $K$ ') are given in Fig. 2.

The typing system satisfies the following properties:

- Proposition 3**
1. (*Weakening*) If  $\Sigma \vdash A : K$  then  $\Sigma, \alpha : K' \vdash A : K$ .
  2. (*Negation preserves typing*) If  $\Sigma \vdash A : K$  then  $\Sigma \vdash A^\perp : K$ .
  3. (*Substitution is well-typed*) If  $\Sigma \vdash A : K$  and  $\Sigma, \alpha : K \vdash B : K'$  then  $\Sigma \vdash B\{\alpha \setminus A\} : K'$ .

It also satisfies Subject reduction:

**Proposition 4 (Subject reduction)** — If  $\Sigma \vdash A : K$  and if  $A \longrightarrow_\beta A'$ , then  $\Sigma \vdash A' : K$ .

### 2.3 Reduction and Typing for Terms and Programs

The reduction system of the lower layer of  $F_\omega^C$ , presented in Fig. 3, applies on programs, but the contextual closure equip both programs and terms with a reduction relation. Recall that the programs  $\{t \mid u\}$  and  $\{u \mid t\}$  are identified, so we consider the reduction relation *modulo* the congruence defined by this identity and we denote it  $\longrightarrow_{F_\omega^C}$ .

---

---

$\{\mu x^A.p \mid t\}$	$\longrightarrow_\mu$	$p\{x \setminus t\}$
$\{\langle t_1, t_2 \rangle \mid \lambda x_1^A x_2^B.p\}$	$\longrightarrow_{\wedge \vee_l}$	$\{t_1 \mid \mu x_1^A.\{t_2 \mid \mu x_2^B.p\}\}$
	or	$\{t_2 \mid \mu x_2^B.\{t_1 \mid \mu x_1^A.p\}\}$
$\{\Lambda \alpha : K . t \mid \langle A, u \rangle\}$	$\longrightarrow_{\vee \exists}$	$\{t\{\alpha \setminus A\} \mid u\}$

---

---

Figure 3: Reduction rules on terms and programs

As in Barbanera and Berardi's symmetric  $\lambda$ -calculus [BB96] or in Curien and Herbelin's  $\lambda\mu\tilde{\mu}$ -calculus [CH00], the critical pair

$$\begin{array}{ccc}
 & \{\mu x^A.p \mid \mu y^{A'}.q\} & \\
 & \swarrow \quad \searrow & \\
 p\{x \setminus \mu y^{A'}.q\} & & q\{y \setminus \mu x^A.p\}
 \end{array}$$

cannot be joined, and in fact reduction is not confluent in general in this layer (see Example 2 below).

Typing contexts for variables of terms, that we simply call *contexts*, are lists of declarations of the form  $(x : A)$ :

**Contexts**  $\Gamma ::= x_1 : A_1, \dots, x_n : A_n$

Since types  $A$  that appear in a context may depend on constructor variables, each context  $\Gamma$  only makes sense in a given signature  $\Sigma$ . In what follows, we say that a context  $\Gamma$  is *well-formed* in a signature  $\Sigma$  and write  $\text{wf}_\Sigma(\Gamma)$  if for all declarations  $(x : A) \in \Gamma$ , the judgement  $\Sigma \vdash A : \star$  is derivable.

From this, we define two judgements, namely:

$\Gamma \vdash_\Sigma t : A$  'In the signature  $\Sigma$  and context  $\Gamma$ , the term  $t$  has type  $A$ '  
 $\Gamma \vdash_\Sigma p \diamond$  'In the signature  $\Sigma$  and context  $\Gamma$ , the program  $p$  is well-formed'

Both judgements are defined by mutual induction from the rules given in Fig. 4.

This typing system satisfies the following properties:

- Proposition 5**
1. (*Weakening of signature*) If  $\Gamma \vdash_\Sigma t : B$  (resp.  $\Gamma \vdash_\Sigma p \diamond$ ) then  $\Gamma \vdash_{\Sigma, \alpha : K} t : B$  (resp.  $\Gamma \vdash_{\Sigma, \alpha : K} p \diamond$ ).
  2. (*Weakening of context*) If  $\Gamma \vdash_\Sigma t : B$  (resp.  $\Gamma \vdash_\Sigma p \diamond$ ) and  $\Sigma \vdash A : K$  then  $\Gamma, x : A \vdash_\Sigma t : B$  (resp.  $\Gamma, x : A \vdash_\Sigma p \diamond$ ).
  3. (*Substitution of constructors is well-typed*) If  $\Sigma \vdash A : K$  and  $\Gamma \vdash_{\Sigma, \alpha : K} t : B$  (resp.  $\Gamma \vdash_{\Sigma, \alpha : K} p \diamond$ ) then  $\Gamma\{\alpha \setminus A\} \vdash_\Sigma t\{\alpha \setminus A\} : B\{\alpha \setminus A\}$  (resp.  $\Gamma\{\alpha \setminus A\} \vdash_\Sigma p\{\alpha \setminus A\} \diamond$ ).
  4. (*Substitution of terms is well-typed*) If  $\Gamma \vdash_\Sigma u : A$  and  $\Gamma, x : A \vdash_\Sigma t : B$  (resp.  $\Gamma, x : A \vdash_\Sigma p \diamond$ ) then  $\Gamma \vdash_\Sigma t\{x \setminus u\} : B$  (resp.  $\Gamma \vdash_\Sigma p\{x \setminus u\} \diamond$ ).

$$\begin{array}{c}
\frac{\text{wf}_\Sigma(\Gamma)}{\Gamma \vdash_\Sigma x : A} (x : A) \in \Gamma \qquad \frac{\Gamma, x : A \vdash_\Sigma p \diamond}{\Gamma \vdash_\Sigma \mu x^A.p : A^\perp} \\
\frac{\Gamma \vdash_\Sigma t : A \quad \Gamma \vdash_\Sigma u : B}{\Gamma \vdash_\Sigma \langle t, u \rangle : A \wedge B} \qquad \frac{\Gamma, x : A, y : B \vdash_\Sigma p \diamond}{\Gamma \vdash_\Sigma \lambda x^A y^B.p : A^\perp \vee B^\perp} \\
\frac{\Gamma \vdash_{\Sigma, \alpha : K} t : B}{\Gamma \vdash_\Sigma \Lambda \alpha : K . t : \forall \alpha : K . B} \qquad \frac{\Sigma \vdash A : K \quad \Gamma \vdash_\Sigma u : B \{ \alpha \setminus A \}}{\Gamma \vdash_\Sigma \langle A, u \rangle : \exists \alpha : K . B} \\
\frac{\Gamma \vdash_\Sigma t : A \quad \Sigma \vdash A' : \star}{\Gamma \vdash_\Sigma t : A'} A =_\beta A' \qquad \frac{\Gamma \vdash_\Sigma t : A \quad \Gamma \vdash_\Sigma u : A^\perp}{\Gamma \vdash_\Sigma \{t \mid u\} \diamond}
\end{array}$$

Figure 4: Typing rules for terms and programs

And again it also satisfies Subject reduction, despite the non-deterministic nature of reduction:

**Proposition 6 (Subject-reduction)**

1. If  $\Gamma \vdash_\Sigma t : A$  and  $t \longrightarrow_{F\mathcal{C}} t'$ , then  $\Gamma \vdash_\Sigma t' : A$ .
2. If  $\Gamma \vdash_\Sigma p \diamond$  and  $p \longrightarrow_{F\mathcal{C}} p'$ , then  $\Gamma \vdash_\Sigma p' \diamond$ .

**Proof:** By simultaneous induction on the judgements  $\Gamma \vdash_\Sigma t : A$  and  $\Gamma \vdash_\Sigma p \diamond$ .  $\square$

**Example 1** Here is a proof of the Law of excluded middle:

$$\frac{\frac{\frac{x : \alpha^\perp, y : \alpha \vdash_\alpha : \star \quad x : \alpha^\perp \quad x : \alpha^\perp, y : \alpha \vdash_\alpha : \star \quad y : \alpha}{x : \alpha^\perp, y : \alpha \vdash_\alpha : \star \{x \mid y\} \diamond}}{\vdash_\alpha : \star \lambda x^{\alpha^\perp} y^\alpha . \{x \mid y\} : \alpha \vee (\alpha^\perp)}}{\vdash \Lambda \alpha : \star . \lambda x^{\alpha^\perp} y^\alpha . \{x \mid y\} : \forall \alpha : \star . \alpha \vee (\alpha^\perp)}$$

**Example 2** Here is Lafont's example of non-confluence. Suppose  $\Gamma \vdash_\alpha : \star p_1 \diamond$  and  $\Gamma \vdash_\alpha : \star p_2 \diamond$ . With  $x \notin \mathcal{FV}(p_1)$  and  $y \notin \mathcal{FV}(p_2)$ , by weakening we get

$$\frac{\frac{\Gamma, x : \alpha \vdash_\alpha : \star p_1 \diamond}{\Gamma \vdash_\alpha : \star \mu x^\alpha . p_1 : \alpha^\perp} \quad \frac{\Gamma, y : \alpha^\perp \vdash_\alpha : \star p_2 \diamond}{\Gamma \vdash_\alpha : \star \mu y^{\alpha^\perp} . p_2 : \alpha}}{\Gamma \vdash_\alpha : \star \{ \mu x^\alpha . p_1 \mid \mu y^{\alpha^\perp} . p_2 \} \diamond}$$

But  $\{ \mu x^\alpha . p_1 \mid \mu y^{\alpha^\perp} . p_2 \} \longrightarrow_\mu^* p_1$  or  $\{ \mu x^\alpha . p_1 \mid \mu y^{\alpha^\perp} . p_2 \} \longrightarrow_\mu^* p_2$ . And unless the system is proof-irrelevant,  $p_1$  and  $p_2$  can be completely different.

Note that, in contrast to Barbanera and Berardi’s symmetric  $\lambda$ -calculus, our design choices for the typing rules are such that, by constraining terms and programs to be linear, we get exactly the multiplicative fragment of linear logic [Gir87].

### 3 Strong normalisation

In this section we prove the strong normalisation of the two layers of  $F_\omega^C$ . In both cases the method is based on the reducibility technique of Tait and Girard [Gir72].

This consists in building a strongly normalising model of the calculus, interpreting kinds (resp. types) as sets of strongly normalising type constructors (resp. pairs of strongly normalising terms). By definition, these sets (resp. pairs of sets) contain the basic constructs that introduce a connective (resp. that introduce dual connectives).

This is sufficient to treat most cases of the induction to prove the soundness theorem (which roughly states that being typed implies being in the model, hence being strongly normalising), but for the other cases we need the property that the interpretation of kinds (resp. types) is *saturated*, so we extend these interpretations by a completion process.

Now the completion process is precisely where the proofs of strong normalisation of the two layers differ: For the upper layer we simply use a completion by bi-orthogonality and this gives us the desired saturation property. For the lower layer, the completion process is obtained by Barbanera and Berardi’s fixpoint construction. We discuss this difference in section 4.

#### 3.1 Strong normalisation of type constructors

In this section we prove that all well-typed constructors are strongly normalisable. For that, let us write  $\text{SN}_C$  the set of all strongly normalisable type constructors.

We call a *stack* (of type constructors) any finite sequence  $S = (A_1, \dots, A_n)$  of type constructors. Given a type constructor  $B$  and a stack  $S = (A_1, \dots, A_n)$ , we define the application  $BS$  by setting  $BS = BA_1 \cdots A_n$ .

We say that a stack  $S = (A_1, \dots, A_n)$  is strongly normalisable when all its elements  $A_1, \dots, A_n$  are strongly normalisable. The set of all strongly normalisable stacks is written  $\text{SN}_C^*$ . In general, applying a strongly normalisable constructor  $B \in \text{SN}_C$  to a strongly normalisable stack  $S \in \text{SN}_C^*$  does not yield a strongly normalisable constructor  $BS$ . In the case where  $BS \in \text{SN}_C$ , we thus say that  $B$  and  $S$  are *orthogonal*, and write  $B \perp S$ .

Given a subset  $X \subset \text{SN}_C$ , we write  $X^\perp$  the subset of  $\text{SN}_C^*$  called the *orthogonal of  $X$*  and defined by

$$X^\perp = \{S \in \text{SN}_C^* \mid B \perp S \text{ for all } B \in X\}.$$

Similarly, the orthogonal  $Y^\perp \subset \text{SN}_C$  of a subset  $Y \subset \text{SN}_C^*$  is defined as

$$Y^\perp = \{B \in \text{SN}_C \mid B \perp S \text{ for all } S \in Y\}.$$

The operation  $X \mapsto X^\perp$  fulfils the usual properties of orthogonality on  $\text{SN}_C$  (as well as on  $\text{SN}_C^*$ ):

1.  $X \subset X'$  entails  $X'^\perp \subset X^\perp$  (contravariance)
2.  $X \subset X^{\perp\perp}$  (closure)
3.  $X^{\perp\perp\perp} = X^\perp$  (tri-orthogonal)

**Definition 1 (Reducibility candidate)** — We call a *reducibility candidate* any subset  $X \subset \text{SN}_C$  such that  $X = X^{\perp\perp}$ .

Notice that reducibility candidates are precisely the subsets  $X \subset \text{SN}_C$  of the form  $X = Y^\perp$  for some subset  $Y \subset \text{SN}_C^*$ . In particular,  $\text{SN}_C$  is a reducibility candidate, since  $\text{SN}_C = \{()\}^\perp$  (writing  $()$  for the empty stack).

Reducibility candidates enjoy the following properties:

**Proposition 7** — *For all reducibility candidates  $X$ :*

1.  $X \subset \text{SN}_C$ ;
2.  $X$  contains all variables  $\alpha$  and negated variables  $\alpha^\perp$ ;
3.  $X$  is closed under  $\beta$ -reduction, that is:  
if  $B \in X$  and  $B \rightarrow_\beta B'$ , then  $B' \in X$ ;
4.  $X$  is saturated, i.e. closed under head  $\beta$ -expansion:  
if  $B\{\alpha \setminus A\} \in X$  and  $A \in \text{SN}_C$ , then  $(\lambda\alpha : K . B)A \in X$ .

**Proof:** Item 1 holds by definition. Item 2 holds since  $\alpha S$  (resp.  $\alpha^\perp S$ ) is strongly normalisable as soon as the stack  $S$  is strongly normalisable. Item 3 holds since strongly normalisable type constructors are closed under  $\beta$ -reduction. Finally, item 4 is a consequence of the following property: If the type constructors  $A$  and  $B\{\alpha \setminus A\}A_1 \cdots A_n$  are strongly normalisable, then so is  $(\lambda\alpha : K . B)AA_1 \cdots A_n$ .  $\square$

**Definition 2 (Set constructions)** We define the following abbreviations:

$$\begin{aligned} X \rightarrow X' &= \{B \in \text{SN}_C \mid \forall A \in X, (BA) \in X'\} \\ \lambda X . X' &= \{\lambda\alpha : K . B \in \text{SN}_C \mid \forall A \in X, B\{\alpha \setminus A\} \in X'\} \end{aligned}$$

**Lemma 8** — *For all subsets  $X \subset \text{SN}_C$  and  $Y \subset \text{SN}_C^*$ ,*

$$X \rightarrow Y^\perp = (\lambda X . Y^\perp)^{\perp\perp}$$

**Proof:** Since  $Y^\perp$  is a reducibility candidate ( $Y^\perp = Y^{\perp\perp\perp}$ ), it is saturated, that is, if  $B\{\alpha \setminus A\} \in Y^\perp$  then  $(\lambda\alpha : K . B) A \in Y^\perp$ . Hence, we get  $\lambda X . Y^\perp \subset X \rightarrow Y^\perp$ .

Now notice that  $X \rightarrow Y^\perp = \{A :: S \mid A \in X, S \in Y^\perp\}^\perp$  (where  $A :: S$  denotes the consing operation on stacks), so it is a reducibility candidate as well, and thus  $(\lambda X . Y^\perp)^{\perp\perp} \subset X \rightarrow Y^\perp$ .

This direction is enough for the proof of strong normalisation, but the reverse direction can also be proved:

Assuming  $C \in X \rightarrow Y^\perp$  and  $S \in (\lambda X . Y^\perp)^\perp$ , we want to show  $C \perp S$ . Since  $C \in \text{SN}_C$  and  $S \in \text{SN}_C^*$ , any infinite reduction sequence would start with:

$$C S \longrightarrow_\beta^* (\lambda\alpha : K . B) S'$$

with  $S \longrightarrow_\beta^* S' \in (\lambda X . Y^\perp)^\perp$  and  $C \longrightarrow_\beta^* \lambda\alpha : K . B \in (X \rightarrow Y^\perp)$ , for which  $\lambda\alpha : K . B \in \lambda X . Y^\perp$ .  $\square$

From this, we interpret each kind  $K$  as a reducibility candidate:

**Definition 3 (Interpretation of kinds)** The interpretation  $[K]$  of a kind  $K$  is a reducibility candidate defined by induction on  $K$  as follows:

$$\begin{aligned} [\star] &= \text{SN}_C \\ [K \rightarrow K'] &= [K] \rightarrow [K'] = (\lambda[K] . [K'])^{\perp\perp} \end{aligned}$$

**Lemma 9** — *If the typing judgment  $\alpha_1 : K_1, \dots, \alpha_n : K_n \vdash B : K$  is derivable, then for all  $A_1 \in [K_1], \dots, A_n \in [K_n]$  one has*

$$B\{\alpha_1, \dots, \alpha_n \setminus A_1, \dots, A_n\} \in [K]$$

(where  $B\{\alpha_1, \dots, \alpha_n \setminus A_1, \dots, A_n\}$  denotes the parallel substitution of the type constructors  $A_1, \dots, A_n$  to the variables  $\alpha_1, \dots, \alpha_n$  in the type constructor  $B$ ).

**Proof:** By induction on the derivation of  $\alpha_1 : K_1, \dots, \alpha_n : K_n \vdash B : K$ .  $\square$

From this we get:

**Theorem 10** — *It  $\Sigma \vdash B : K$ , then  $B$  is strongly normalisable.*

**Proof:** Apply lemma 9 with  $A_1 = \alpha_1, \dots, A_n = \alpha_n$  (identity substitution), using item 2 of Prop. 7.  $\square$

## 3.2 Strong normalisation of terms

This proof is adapted from those of [BB96, Pol04, DGLL05] for the symmetric  $\lambda$ -calculus [BB96], the  $\bar{\lambda}\mu\tilde{\mu}$ -calculus [CH00], and the *dual calculus* [Wad03] (which are based on a bi-sided sequent calculi), respectively. They all use Barbanera and Berardi's *symmetric candidates*, with a fixpoint construct to capture the non-confluence of classical logic.

As usual with the reducibility method we construct a model of the calculus by interpreting types (here, type constructors and type lists) as sets of terms. However, the second-order quantification that appears in System  $F$  or  $F_\omega$  is conveniently interpreted as a set intersection only if terms do not display type annotations. We therefore start by defining such term and programs, i.e. Curry-style terms and programs:

$$\begin{array}{ll} \text{Curry-style terms} & t, u, v, \dots ::= x \mid \mu x.p \mid \langle t, u \rangle \mid \lambda xy.p \mid \Lambda_.t \mid \langle \_, t \rangle \\ \text{Curry-style programs} & p ::= \{t \mid u\} \end{array}$$

The corresponding reduction rules, that are shown in Fig. 5, define the reductions  $\longrightarrow_{F_\omega^c}$  and the set SN of Curry-style terms and Curry-style programs.

$$\begin{array}{ll} \hline \hline \{\mu x.p \mid t\} & \longrightarrow p\{x \setminus t\} \\ \{\langle t_1, t_2 \rangle \mid \lambda x_1 x_2.p\} & \longrightarrow \{t_1 \mid \mu x_1.\{t_2 \mid \mu x_2.p\}\} \\ & \text{or} \\ & \{t_2 \mid \mu x_2.\{t_1 \mid \mu x_1.p\}\} \\ \{\Lambda_.t \mid \langle \_, u \rangle\} & \longrightarrow \{t \mid u\} \\ \hline \hline \end{array}$$

Figure 5: Reductions without types

**Definition 4** — The type-erasure operation from terms (resp. programs) to Curry-style terms (resp. Curry-style programs) is recursively defined by:

$$\begin{array}{ll} \|x\| & = x \\ \|\langle t, u \rangle\| & = \langle \|t\|, \|u\| \rangle \\ \|\lambda x^A y^B.p\| & = \lambda xy.\|p\| \\ \|\mu x^A.p\| & = \mu x.\|p\| \\ \|\Lambda\alpha : K.t\| & = \Lambda_.\|t\| \\ \|\langle A, t \rangle\| & = \langle \_, \|t\| \rangle \\ \|\{t \mid u\}\| & = \{\|t\| \mid \|u\|\} \end{array}$$

Note that by erasing the types we still keep, in Curry-style programs, a trace of the constructs introducing the  $\forall$  and  $\exists$  quantifiers. Thus, it is slightly different from the traditional Curry-style polymorphism of system  $F$  or  $F_\omega$ , but this trace turns out to be important in classical logic: if we removed it, we could make some  $\mu$ - $\mu$  critical pair appear that was not present in the original program with type annotations, and one of the two reductions might not satisfy subject reduction.<sup>2</sup>

<sup>2</sup>This is a general problem of polymorphism and classical logic with non-confluent reduction: for instance the spirit of *intersection types* [CD78], which represent finite polymorphism, is to give several types to *the same program*, free from any trace of where the typing rules for intersection types have been used in its typing derivation. In that case again, non-confluent reductions of classical logic often fail to satisfy subject reduction.

**Lemma 11** — *Provided all types in a term  $t$  are strongly normalising (for  $\beta$ ), if  $\|t\| \in \text{SN}$  then  $t \in \text{SN}$ .*

**Proof:** Let  $\mathcal{M}(t)$  be the multiset of all the types and kinds appearing in  $t$ , equipped with the multiset order based on the terminating  $\beta$ -reduction on types.

Every reduction from  $t$  decrease the pair  $(\|t\|, \mathcal{M}(t))$  in lexicographic order.  $\square$

**Definition 5 (Orthogonality)**

- We say that that a Curry-style term  $t$  is *orthogonal* to a Curry-style term  $u$ , written  $t \perp u$ , if  $\{t \mid u\} \in \text{SN}$ .
- We say that that a set  $\mathcal{U}$  of Curry-style terms is *orthogonal* to a set  $\mathcal{V}$  of Curry-style terms, written  $\mathcal{U} \perp \mathcal{V}$ , if  $\forall t \in \mathcal{U}, \forall u \in \mathcal{V}, t \perp u$ .

**Remark 12** — If  $t\{x \setminus v\} \perp u\{x \setminus v\}$ , then  $t \perp u$  and  $\mu x.\{t \mid u\} \in \text{SN}$ .

**Definition 6** — A set  $\mathcal{U}$  of Curry-style terms is *simple* if it is non-empty and it contains no Curry-style term of the form  $\mu x.p$ .

**Definition 7** — A pair  $(\mathcal{U}, \mathcal{V})$  of sets of Curry-style terms is *saturated* if:

- $\text{Var} \subseteq \mathcal{U}$  and  $\text{Var} \subseteq \mathcal{V}$
- $\{\mu x.\{t \mid u\} \mid \forall v \in \mathcal{V}, t\{x \setminus v\} \perp u\{x \setminus v\}\} \subseteq \mathcal{U}$   
 $\{\mu x.\{t \mid u\} \mid \forall v \in \mathcal{U}, t\{x \setminus v\} \perp u\{x \setminus v\}\} \subseteq \mathcal{V}$ .

**Definition 8** — Whenever  $\mathcal{U}$  is simple, we define the following function  $\Phi_{\mathcal{U}}(\mathcal{V}) = \mathcal{U} \cup \text{Var} \cup \{\mu x.\{t \mid u\} \mid \forall v \in \mathcal{V}, t\{x \setminus v\} \perp u\{x \setminus v\}\}$ .

**Remark 13** — For all simple  $\mathcal{U}$ ,  $\Phi_{\mathcal{U}}$  is anti-monotone. Hence, for any simple  $\mathcal{U}$  and  $\mathcal{V}$ ,  $\Phi_{\mathcal{U}} \circ \Phi_{\mathcal{V}}$  is monotone, so it admits a fixpoint  $\mathcal{U}' \supseteq \mathcal{U}$ .

**Theorem 14** — *Assume that  $\mathcal{U}$  and  $\mathcal{V}$  are simple with  $\mathcal{U} \perp \mathcal{V}$ . There exist  $\mathcal{U}'$  and  $\mathcal{V}'$  such that  $\mathcal{U} \subseteq \mathcal{U}'$  and  $\mathcal{V} \subseteq \mathcal{V}'$ ,  $\mathcal{U}' \perp \mathcal{V}'$  and  $(\mathcal{U}', \mathcal{V}')$  is saturated.*

**Proof:** Let  $\mathcal{U}'$  be a fixed point of  $\Phi_{\mathcal{U}} \circ \Phi_{\mathcal{V}}$ , and let  $\mathcal{V}' = \Phi_{\mathcal{V}}(\mathcal{U}')$ . We have

$$\begin{aligned} \mathcal{U}' &= \Phi_{\mathcal{U}}(\mathcal{V}') = \mathcal{U} \cup \text{Var} \cup \{\mu x.\{t \mid u\} \mid \forall v \in \mathcal{V}', t\{x \setminus v\} \perp u\{x \setminus v\}\} \\ \mathcal{V}' &= \Phi_{\mathcal{V}}(\mathcal{U}') = \mathcal{V} \cup \text{Var} \cup \{\mu x.\{t \mid u\} \mid \forall v \in \mathcal{U}', t\{x \setminus v\} \perp u\{x \setminus v\}\} \end{aligned}$$

It is clearly saturated. We now prove that  $\mathcal{U}' \perp \mathcal{V}'$ .

Since  $\mathcal{U} \perp \mathcal{V}$  and  $\mathcal{U}$  and  $\mathcal{V}$  are non-empty, we have  $\mathcal{U} \subseteq \text{SN}$  and  $\mathcal{V} \subseteq \text{SN}$ . We also have  $\text{Var} \subseteq \text{SN}$ . Finally, by Remark 12, we conclude  $\mathcal{U}' \subseteq \text{SN}$  and  $\mathcal{V}' \subseteq \text{SN}$ .

Now assume  $u \in \mathcal{U}'$  and  $v \in \mathcal{V}'$ . We show  $u \perp v$  by lexicographical induction on the length of the longest derivation starting from  $u \in \text{SN}$  and that of the longest derivation starting from  $v \in \text{SN}$ .

If  $u \in \mathcal{U}$  and  $v \in \mathcal{V}$  then  $u \perp v$  because  $\mathcal{U} \perp \mathcal{V}$ . If not, we prove  $u \perp v$  by showing that whenever  $\{u \mid v\} \rightarrow_{F_{\mathcal{C}}} p$ , then  $p \in \text{SN}$ .

- If  $\{u \mid v\} \longrightarrow_{F_\omega^c} \{u' \mid v\}$  or  $\{u \mid v\} \longrightarrow_{F_\omega^c} \{u \mid v'\}$ , the induction hypothesis applies.
- The only other case is  $u = \mu x.p$  (resp.  $v = \mu x.p$ ) and  $\{u \mid v\} \longrightarrow_{F_\omega^c} p\{x \setminus v\}$  (resp.  $\{u \mid v\} \longrightarrow_{F_\omega^c} p\{x \setminus u\}$ ). But since  $u \in \mathcal{U}'$  and  $v \in \mathcal{V}'$ , we know that  $p\{x \setminus v\} \in \text{SN}$  (resp.  $p\{x \setminus u\} \in \text{SN}$ ).

□

**Definition 9** — Now we interpret kinds:

- The interpretation  $\llbracket K \rrbracket$  of a kind  $K$  is defined by induction on  $K$  as follows:

$$\begin{aligned} \llbracket \star \rrbracket &= \{(\mathcal{U}, \mathcal{V}) \mid \mathcal{U} \perp \mathcal{V} \text{ and } (\mathcal{U}, \mathcal{V}) \text{ is saturated}\} \\ \llbracket K \rightarrow K' \rrbracket &= \llbracket K' \rrbracket^{\llbracket K \rrbracket} \end{aligned}$$

where  $\llbracket K' \rrbracket^{\llbracket K \rrbracket}$  is simply the set of (total) functions from  $\llbracket K \rrbracket$  to  $\llbracket K' \rrbracket$ .

- Given a pair  $p \in \llbracket \star \rrbracket$ , we write  $p^+$  (resp.  $p^-$ ) its first (resp. second) component.
- We also define the function  $\text{swap}_K : \llbracket K \rrbracket \rightarrow \llbracket K \rrbracket$  by induction on  $K$ :

$$\begin{aligned} \text{swap}_\star(\mathcal{U}, \mathcal{V}) &= (\mathcal{V}, \mathcal{U}) \\ \text{swap}_{K \rightarrow K'}(f) &= \text{swap}_{K'} \circ f \end{aligned}$$

- Let  $\text{swap} : (\bigcup_K \llbracket K \rrbracket) \rightarrow (\bigcup_K \llbracket K \rrbracket)$  be the disjoint union of all the  $\text{swap}_K$ .

**Definition 10** — Let  $\mathcal{U}$  and  $\mathcal{V}$  be sets of Curry-style terms. We set the following definitions:

$$\begin{aligned} \langle \mathcal{U}, \mathcal{V} \rangle &= \{\langle u, v \rangle \mid u \in \mathcal{U}, v \in \mathcal{V}\} \\ \lambda \mathcal{U} \mathcal{V} . \diamond &= \{\lambda x y . p \mid \forall u \in \mathcal{U} \forall v \in \mathcal{V} p\{x, y \setminus u, v\} \in \text{SN}\} \\ \Lambda \_ . \mathcal{U} &= \{\Lambda \_ . u \mid u \in \mathcal{U}\} \\ \langle \_ , \mathcal{U} \rangle &= \{\langle \_ , u \rangle \mid u \in \mathcal{U}\} \end{aligned}$$

**Remark 15**

1. The sets  $\langle \mathcal{U}, \mathcal{V} \rangle$ ,  $\lambda \mathcal{U} \mathcal{V} . \diamond$ ,  $\Lambda \_ . \mathcal{U}$  and  $\langle \_ , \mathcal{U} \rangle$  are always simple.
2. If  $\mathcal{U} \subseteq \text{SN}^{F_\omega^c}$  and  $\mathcal{V} \subseteq \text{SN}^{F_\omega^c}$  then  $\langle \mathcal{U}, \mathcal{V} \rangle \perp \lambda \mathcal{U} \mathcal{V} . \diamond$ .
3. If  $\mathcal{U} \perp \mathcal{V}$  then  $\Lambda \_ . \mathcal{U} \perp \langle \_ , \mathcal{V} \rangle$ .

**Definition 11** — We say that a mapping  $\rho : \text{Var}^T \rightarrow \bigcup_K \llbracket K \rrbracket$  is *compatible* with  $\Sigma$  if  $\forall (\alpha : K) \in \Sigma, \rho(\alpha) \in \llbracket K \rrbracket$ .

**Definition 12** — For each  $A$  such that  $\Sigma \vdash A : K$  for some  $K$ , and for each  $\rho$  compatible with  $\Sigma$ , we define  $\llbracket A \rrbracket_\rho \in \llbracket K \rrbracket$  as follows:

$$\begin{aligned}
\llbracket \alpha \rrbracket_\rho &= \rho(\alpha) \\
\llbracket \alpha^\perp \rrbracket_\rho &= \text{swap}(\rho(\alpha)) \\
\llbracket A \wedge B \rrbracket_\rho &= \text{any saturated } (\mathcal{U}, \mathcal{V}) \text{ such that} \\
&\quad \langle \llbracket A \rrbracket_\rho^+, \llbracket B \rrbracket_\rho^+ \rangle \subseteq \mathcal{U} \\
&\quad \lambda \llbracket A \rrbracket_\rho^+ \llbracket B \rrbracket_\rho^+ . \diamond \subseteq \mathcal{V} \\
&\quad \mathcal{U} \perp \mathcal{V} \\
\llbracket A \vee B \rrbracket_\rho &= \text{any saturated } (\mathcal{U}, \mathcal{V}) \text{ such that} \\
&\quad \lambda \llbracket A \rrbracket_\rho^- \llbracket B \rrbracket_\rho^- . \diamond \subseteq \mathcal{U} \\
&\quad \langle \llbracket A \rrbracket_\rho^-, \llbracket B \rrbracket_\rho^- \rangle \subseteq \mathcal{V} \\
&\quad \mathcal{U} \perp \mathcal{V} \\
\llbracket \forall \alpha : K' . A \rrbracket_\rho &= \text{any saturated } (\mathcal{U}, \mathcal{V}) \text{ such that} \\
&\quad \Lambda_- . \bigcap_{h \in \llbracket K' \rrbracket} \llbracket A \rrbracket_{\rho, \alpha \mapsto h}^+ \subseteq \mathcal{U} \\
&\quad \langle \_ , \bigcup_{h \in \llbracket K' \rrbracket} \llbracket A \rrbracket_{\rho, \alpha \mapsto h}^- \rangle \subseteq \mathcal{V} \\
&\quad \mathcal{U} \perp \mathcal{V} \\
\llbracket \exists \alpha : K' . A \rrbracket_\rho &= \text{any saturated } (\mathcal{U}, \mathcal{V}) \text{ such that} \\
&\quad \langle \_ , \bigcup_{h \in \llbracket K' \rrbracket} \llbracket A \rrbracket_{\rho, \alpha \mapsto h}^+ \rangle \subseteq \mathcal{U} \\
&\quad \Lambda_- . \bigcap_{h \in \llbracket K' \rrbracket} \llbracket A \rrbracket_{\rho, \alpha \mapsto h}^- \subseteq \mathcal{V} \\
&\quad \mathcal{U} \perp \mathcal{V} \\
\llbracket \lambda \alpha : K' . A \rrbracket_\rho &= h \in \llbracket K' \rrbracket \mapsto \llbracket A \rrbracket_{\rho, \alpha \mapsto h} \\
\llbracket A B \rrbracket_\rho &= (\llbracket A \rrbracket_\rho)(\llbracket B \rrbracket_\rho)
\end{aligned}$$

The soundness of the definition inductively relies on the fact that  $\llbracket A \rrbracket_\rho \in \llbracket K \rrbracket$ ,  $\rho$  keeps being compatible with  $\Sigma$ , and  $\llbracket A \rrbracket_\rho^+ \perp \llbracket A \rrbracket_\rho^-$ . The existence of the saturated extensions in the case of  $A \wedge B$ ,  $A \vee B$ ,  $\forall \alpha : K' . A$  and  $\exists \alpha : K' . A$  is given by Theorem 14.

**Remark 16** • Note that  $\llbracket A^\perp \rrbracket_\rho = \text{swap} \llbracket A \rrbracket_\rho$ .

- $\llbracket A \rrbracket_{\rho, \alpha \mapsto \llbracket B \rrbracket_\rho} = \llbracket A \{ \alpha \setminus B \} \rrbracket_\rho$
- If  $A \longrightarrow_\beta B$  then  $\llbracket A \rrbracket_\rho = \llbracket B \rrbracket_\rho$ .
- If  $\Sigma \vdash A : \star$ , then  $\llbracket A \rrbracket_\rho$  is saturated, with  $\llbracket A \rrbracket_\rho^+ \subseteq \text{SN}$  and  $\llbracket A \rrbracket_\rho^- \subseteq \text{SN}$ .

**Theorem 17** — If  $x_1 : A_1, \dots, x_n : A_n \vdash_\Sigma t : A$  then for all  $\rho$  compatible with  $\Sigma$ , and for all  $t_1 \in \llbracket A_1 \rrbracket_\rho^+, \dots, t_n \in \llbracket A_n \rrbracket_\rho^+$  we have:

$$\|t\| \{x_1, \dots, x_n \setminus t_1, \dots, t_n\} \in \llbracket A \rrbracket_\rho^+$$

**Proof:** By induction on the typing tree. □

**Corollary 18** — If  $x_1 : A_1, \dots, x_n : A_n \vdash_\Sigma t : A$  then  $t \in \text{SN}$ .

**Proof:** We first prove that we can find a  $\rho$  compatible with  $\Sigma$  (for  $\alpha : \star$ , take  $\rho(\alpha)$  to be any saturated extension of  $(\text{Var}, \text{Var})$ ). Then we can apply Theorem 17 and conclude by Lemma 11. □

## 4 Orthogonality and saturation

As mentioned in the introduction of section 3, the similarity between the proof of strong normalisation of the upper layer and that of the lower layer is striking.

However, while in the upper layer the saturation of the interpretation of kinds is obtained by a bi-orthogonal completion, it is important to understand why, for the lower layer, we used another notion of completion using fixpoints instead.

The reason is that in general, if the pair  $(\mathcal{U}, \mathcal{V})$  is simple and orthogonal, the extension  $(\mathcal{U}^{\perp\perp}, \mathcal{V}^{\perp\perp})$  might not be saturated in the sense of Definition 7 (while in the upper layer such a completion by bi-orthogonality ensures the corresponding notion of saturation). This was a conjecture set in [LM06], which we prove in this section by providing counter-examples.

Technically, the presence of the  $\mu$ - $\mu$  critical pair makes the proof of Theorem 7.3 impossible to adapt to the non-confluent case of the lower layer. This lack of saturation is the motivation for the fixpoint construction in the interpretation of types, instead of the bi-orthogonal construction.

Note that [DN05b] already notices that “the technique using the usual candidates of reducibility does not work” for the non-confluent reductions of classical logic (that they express in the  $\lambda\mu$ -calculus [Par92]). However, their counter-examples translate in our setting to the fact that even if  $t$  and  $p\{x \setminus t\}$  are in SN,  $\{\mu x.p \mid t\}$  need not be in SN. This is quite direct, but the method of completion by bi-orthogonality is more subtle: Indeed, we claim here that a bi-orthogonal extension  $(\mathcal{U}^{\perp\perp}, \mathcal{V}^{\perp\perp})$  (with  $\mathcal{V}^{\perp\perp} = \mathcal{U}^{\perp}$  and  $\mathcal{U}^{\perp\perp} = \mathcal{V}^{\perp}$ ) need not be saturated. In other words, there exist  $t \in \mathcal{V}^{\perp\perp}$  and  $p\{x \setminus t\} \in \text{SN}$ , such that  $\mu x.p \notin \mathcal{U}^{\perp\perp}$  (or the symmetric situation, swapping  $\mathcal{U}$  and  $\mathcal{V}$ ). Indeed, we do obtain this from  $\{\mu x.p \mid t\} \notin \text{SN}$ , but the counter-examples of [DN05b] only provide this with  $t \in \text{SN}$  instead of  $t \in \mathcal{V}^{\perp\perp} \subseteq \text{SN}$ .

### 4.1 A counter-example

**Remark 19** — We have the following equivalences for all programs  $p, q$  and for all terms  $t$ :

1.  $\{\mu x.p \mid \mu y.q\} \in \text{SN}$  iff  $p\{x \setminus \mu y.q\} \in \text{SN}$  and  $q\{y \setminus \mu x.p\} \in \text{SN}$ .
2. If the term  $t$  is not a  $\mu$ -abstraction, then  
 $\{\mu x.p \mid t\} \in \text{SN}$  iff  $t \in \text{SN}$  and  $p\{x \setminus t\} \in \text{SN}$ .

We write  $p + q$  for the non-deterministic composition of programs  $\{\mu \_ .p \mid \mu \_ .q\}$ . (where  $\_$  denotes any fresh variable), which reduces to both  $p$  and  $q$ . We have the equivalence:

$$(p + q) \in \text{SN} \quad \text{iff} \quad p \in \text{SN} \quad \text{and} \quad q \in \text{SN}.$$

Let  $\delta = \mu x.\{x \mid x\}$ . The counter-example is the following:

**Proposition 20 (Counter-example to saturation)**

— The pair  $(\{\delta\}^\perp, \{\delta\}^{\perp\perp})$  is not saturated.

To prove this proposition, let us consider the program

$$p = \{x \mid a\} + \{x \mid b\},$$

where  $a$  and  $b$  are two normal terms such that

$$\{a, b\} \perp \delta \quad \text{and} \quad a \not\perp b.$$

Obvious choices for  $a$  and  $b$  are  $\langle \delta, \delta \rangle$  and  $\lambda x_1 x_2. \{x_1 \mid x_2\}$ , respectively.

**Lemma 21** — For all  $t \in \{\delta\}^{\perp\perp}$ , we have  $p\{x \setminus t\} \in \text{SN}$ .

**Proof:** Let  $t \in \{\delta\}^{\perp\perp}$ . Since  $a, b \in \{\delta\}^\perp$ , we have  $\{t \mid a\} \in \text{SN}$  and  $\{t \mid b\} \in \text{SN}$ , hence  $p\{x \setminus t\} = \{t \mid a\} + \{t \mid b\} \in \text{SN}$  from Prop. 19.  $\square$

**Lemma 22** —  $\mu x.p \notin \{\delta\}^\perp$ .

**Proof:** Reduction of  $\{\mu x.p \mid \delta\}$  yields the following sequence:

$$\begin{aligned} \{\mu x.p \mid \delta\} &\longrightarrow_{F_\omega^c} \{\mu x.p \mid \mu x.p\} \\ &\longrightarrow_{F_\omega^c} \{\mu x.p \mid a\} + \{\mu x.p \mid b\} \\ &\longrightarrow_{F_\omega^c} \{\mu x.p \mid a\} \\ &\longrightarrow_{F_\omega^c} \{a \mid a\} + \{a \mid b\} \\ &\longrightarrow_{F_\omega^c} \{a \mid b\} \notin \text{SN}, \end{aligned}$$

hence  $\mu x.p \notin \{\delta\}^\perp$ .  $\square$

Lemmas 21 and 22 complete the proof of Prop. 20.

## 4.2 Perfect normalisation and a refined counter-example

The counter-example presented in section 4.1 relies on two terms  $a$  and  $b$  that are orthogonal to  $\delta$ , that is, such that

$$\{a \mid \delta\} \in \text{SN} \quad \text{and} \quad \{b \mid \delta\} \in \text{SN}.$$

It is interesting to notice that for the choice of  $a$  and  $b$  we gave above, the strong normalisation of both programs  $\{a \mid \delta\}$  and  $\{b \mid \delta\}$  relies on the fact that all reduction sequences eventually block on an ‘incestuous program’ of the form  $\{\langle t_1, t_2 \rangle \mid \langle u_1, u_2 \rangle\}$  or  $\{\lambda x_1 x_2.p \mid \lambda y_1 y_2.q\}$ , that is, on a program formed by applying two constructions related to the same connective (instead of constructions related to dual connectives):

$$\begin{aligned} \{a \mid \delta\} &= \{\langle \delta, \delta \rangle \mid \delta\} \longrightarrow_{F_\omega^c} \{\langle \delta, \delta \rangle \mid \langle \delta, \delta \rangle\} \quad \text{and} \\ \{b \mid \delta\} &= \{\lambda x_1 x_2. \{x_1 \mid x_2\} \mid \delta\} \longrightarrow_{F_\omega^c} \{\lambda x_1 x_2. \{x_1 \mid x_2\} \mid \lambda x_1 x_2. \{x_1 \mid x_2\}\} \end{aligned}$$

Of course, the computations above should be considered as ill-typed in any reasonable typing system, and thus should be rejected.

On the other hand, the orthogonality relation  $t \perp u$  is intended to express some kind of correctness about the execution of the program  $\{t \mid u\}$ . Thus if we consider that the strong normalisation of  $\{a \mid \delta\}$  and  $\{b \mid \delta\}$  is purely artificial, one should restrict the definition of orthogonality in such a way that the pairs  $(a, \delta)$  and  $(b, \delta)$  are rejected. This naturally leads to the following definition:

**Definition 13 (Perfectly normalising program)** — A program  $p$  (resp. a term  $t$ ) is said to be *perfectly normalising* if it is strongly normalising, and if for all  $p'$  such that  $p \xrightarrow{*}_{F\omega} p'$  (resp. all  $t'$  such that  $t \xrightarrow{*}_{F\omega} t'$ ), the program  $p'$  (the term  $t'$ ) contains no incestuous program as a sub-term.

The set of all perfectly normalising programs and terms —which is a subset of the set SN of all strongly normalising programs and terms— is written PN. Perfect normalisation enjoys similar properties as strong normalisation:

**Remark 23** — We have the following equivalences for all programs  $p, q$  and for all terms  $t$ :

1.  $\{\mu x.p \mid \mu y.q\} \in \text{PN}$  iff  $p\{x \setminus \mu y.q\} \in \text{PN}$  and  $q\{y \setminus \mu x.p\} \in \text{PN}$ .
2. If the term  $t$  is not a  $\mu$ -abstraction, then  $\{\mu x.p \mid t\} \in \text{PN}$  iff  $t \in \text{PN}$  and  $p\{x \setminus t\} \in \text{PN}$ .

The notion of perfect normalisation induces a new orthogonality relation —still written  $t \perp u$ — on the set PN of perfectly normalising terms, setting:

$$t \perp u = \{t \mid u\} \in \text{PN}.$$

In this setting, the counter-example of section 4.1 does not work anymore, since  $a, b \notin \{\delta\}^\perp$  (using the new definition of the operator  $\mathcal{U} \mapsto \mathcal{U}^\perp$ ).

Thus, we can still ask the question whether pairs of sets of terms of the form  $(\mathcal{U}^{\perp\perp}, \mathcal{V}^{\perp\perp})$  (according to the new definition of orthogonality) are always saturated or not.

Again, the answer is negative, but the counter-example is more subtle. We replace the symmetric self-application  $\delta = \mu x.\{x \mid x\}$  by a notion of self-application coming from the  $\lambda$ -calculus

$$\delta = \mu x.\{x \mid \langle x, z \rangle\},$$

where  $z$  denotes a fixed free variable.

**Proposition 24** — *The pair  $(\{\delta\}^\perp, \{\delta\}^{\perp\perp})$  is not saturated. (Where  $\perp$  refers to perfectly normalising orthogonality.)*

Again, the idea is to consider two terms  $a$  and  $b$  such that  $\{a \mid \delta\} \in \text{PN}$ ,  $\{b \mid \delta\} \in \text{PN}$  (intuitively: the  $\lambda$ -terms  $aa$  and  $bb$  strongly normalise), but such that  $\{b \mid \langle a, z \rangle\} \notin \text{PN}$  (intuitively: the  $\lambda$ -term  $ba$  diverges). For that, consider the following terms

$$\begin{aligned}\Delta &= \lambda xy. \{x \mid \langle x, y \rangle\} && (\approx \lambda x. xx) \\ a &= \lambda _y. \{\Delta \mid y\} && (\approx \mathbf{K}\Delta) \\ b &= \lambda xy. \{x \mid \langle z, \langle \Delta, y \rangle \rangle\} && (\approx \lambda x. xz\Delta)\end{aligned}$$

and set again

$$p = \{a \mid x\} + \{b \mid x\}.$$

**Lemma 25** — For all  $t \in \{\delta\}^{\perp\perp}$ , we have  $p\{x \setminus t\} \in \text{PN}$ .

**Proof:** In order to check that  $\{a \mid \delta\} \in \text{PN}$  and  $\{b \mid \delta\} \in \text{PN}$ , we now have to check that these programs do not reduce to programs containing incestuous pairs. Indeed, the only reductions of these programs are:

$$\begin{aligned}\{a \mid \delta\} &\longrightarrow_{F_\omega^c} \{a \mid \langle a, z \rangle\} \longrightarrow_{F_\omega^c} \{\Delta \mid z\} \\ \{b \mid \delta\} &\longrightarrow_{F_\omega^c} \{b \mid \langle b, z \rangle\} \longrightarrow_{F_\omega^c} \{b \mid \langle z, \langle \Delta, z \rangle \rangle\} \longrightarrow_{F_\omega^c} \{z \mid \langle z, \langle \Delta, \langle \Delta, z \rangle \rangle \rangle\}\end{aligned}$$

Hence  $a, b \in \{\delta\}^\perp$ . Assume that  $t \in \{\delta\}^{\perp\perp}$ . We thus have  $\{a \mid t\} \in \text{PN}$  and  $\{b \mid t\} \in \text{PN}$ , hence  $\{a \mid t\} + \{b \mid t\} = p\{x \setminus t\} \in \text{PN}$  from Prop. 23.  $\square$

**Lemma 26** —  $\mu x.p \notin \{\delta\}^\perp$ .

**Proof:** Reduction of  $\{\mu x.p \mid \delta\}$  yields the following sequence:

$$\begin{aligned}\{\mu x.p \mid \delta\} &\longrightarrow_{F_\omega^c} \{\mu x.p \mid \langle \mu x.p, z \rangle\} \\ &\longrightarrow_{F_\omega^c} \{a \mid \langle \mu x.p, z \rangle\} + \{b \mid \langle \mu x.p, z \rangle\} \\ &\longrightarrow_{F_\omega^c} \{b \mid \langle \mu x.p, z \rangle\} \\ &\longrightarrow_{F_\omega^c} \{\mu x.p \mid \langle z, \langle \Delta, z \rangle \rangle\} \\ &\longrightarrow_{F_\omega^c} \{a \mid \langle z, \langle \Delta, z \rangle \rangle\} + \{b \mid \langle z, \langle \Delta, z \rangle \rangle\} \\ &\longrightarrow_{F_\omega^c} \{a \mid \langle z, \langle \Delta, z \rangle \rangle\} \\ &\longrightarrow_{F_\omega^c} \{\Delta \mid \langle \Delta, z \rangle\} \\ &\longrightarrow_{F_\omega^c} \{\Delta \mid \langle \Delta, z \rangle\} \notin \text{PN}\end{aligned}$$

hence  $\mu x.p \notin \{\delta\}^\perp$ .  $\square$

Lemmas 25 and 26 complete the proof of Prop. 24.

## 5 Logical Properties

### 5.1 Consistency

The consistency of  $F_\omega^C$  follows from Corollary 18 using a simple combinatorial argument. Let us first notice that all untyped programs that are in normal form are of one of the following thirteen forms:

VARIABLE-VARIABLE	$\{x \mid y\}$
VARIABLE-PAIR	$\{x \mid \lambda x^A y^B . p\}$
VARIABLE-LAMBDA	$\{x \mid \langle t, u \rangle\}$
VARIABLE- $\forall$ LAMBDA	$\{x \mid \Lambda \alpha : K . t\}$
VARIABLE- $\exists$ WITNESS	$\{x \mid \langle A, t \rangle\}$
PAIR-PAIR	$\{\langle t_1, u_1 \rangle \mid \langle t_2, u_2 \rangle\}$
LAMBDA-LAMBDA	$\{\lambda x_1^{A_1} y_1^{B_1} . p_1 \mid \lambda x_2^{A_2} y_2^{B_2} . p_2\}$
$\forall$ LAMBDA- $\forall$ LAMBDA	$\{\Lambda \alpha_1 : K . t_1 \mid \Lambda \alpha_2 : K . t_2\}$
$\exists$ WITNESS- $\exists$ WITNESS	$\{\langle A_1, t_1 \rangle \mid \langle A_2, t_2 \rangle\}$
LAMBDA- $\forall$ LAMBDA	$\{\lambda x_1^{A_1} y_1^{B_1} . p_1 \mid \Lambda \alpha : K . t_2\}$
PAIR- $\forall$ LAMBDA	$\{\langle t_1, u_1 \rangle \mid \Lambda \alpha : K . t_2\}$
LAMBDA- $\exists$ WITNESS	$\{\lambda x_1^{A_1} y_1^{B_1} . p_1 \mid \langle A_2, t_2 \rangle\}$
PAIR- $\exists$ WITNESS	$\{\langle t_1, u_1 \rangle \mid \langle A_2, t_2 \rangle\}$

However, the last eight forms are incestuous, so if we consider only typed programs, they are ruled out for typing reasons, indeed:

**Lemma 27** *There is no closed typed program in normal form.*

**Proof:** In each of the eight last forms, both members introduce a main connective or quantifier which is not the dual of the one introduced on the other side, which contradicts the typing rule of programs. All the remaining forms have a free variable, namely  $x$ .  $\square$

Hence we get the logical consistency of system  $F_\omega^C$ .

**Theorem 28 (Consistency)** *There is no closed typed program in  $F_\omega^C$ .*

**Proof:** It suffices to combine Lemma 27 with Corollary 18 and Theorem 6.  $\square$

### 5.2 Translating $F_\omega + \text{DNE}$ into $F_\omega^C$

The definition of implication  $A \Rightarrow B$  as  $(A^\perp) \vee B$  naturally suggests a translation from system  $F_\omega$  to system  $F_\omega^C$ . We annotate sequents in  $F_\omega$  using  $\vdash^{F_\omega}$ .

The translation proceeds as follows: each kind of  $F_\omega$  is translated as itself, and each type constructor  $A$  of  $F_\omega$  is translated as a type constructor  $A^*$  of  $F_\omega^C$

by the equations

$$\begin{aligned}
\alpha^* &= \alpha \\
(\forall \alpha : K . A)^* &= \forall \alpha : K . A^* \\
(A \Rightarrow B)^* &= A^* \perp \vee B^* \\
(\lambda \alpha : K . B)^* &= \lambda \alpha : K . B^* \\
(B A)^* &= B^* A^*
\end{aligned}$$

We then easily check that

**Proposition 29** — *If  $\Sigma \vdash^{F_\omega} A : K$ , then  $\Sigma \vdash A^* : K$ .*

**Proposition 30** — *If  $A \longrightarrow_\beta B$ , then  $A^* \longrightarrow_\beta B^*$ .*

We now translate proof-terms, adapting Prawitz’s translation of natural deduction into sequent calculus, this time using Curry-style terms and programs, because without a typing derivation for the terms of  $F_\omega$  we lack some type annotations to place in the encoding.

**Definition 14 (Encoding of terms)** The encoding  $u^*$  of a term  $u$  of  $F_\omega$  is defined by induction on  $u$  as described in Fig. 6. It relies on an auxiliary encoding that maps  $u$  to a program  $u_t^*$  and that is parameterised by a term  $t$  of  $F_\omega^C$ .

$x^*$	$=$	$x$
$\lambda x^A . u^*$	$=$	$\lambda xy . u_y^*$
$\Lambda \alpha : K . u^*$	$=$	$\Lambda \_ . u^*$
$u^*$	$=$	$\mu y . u_y^*$ otherwise
$(u u')_t^*$	$=$	$u_{\langle u', t \rangle}^*$
$(u A)_t^*$	$=$	$u_{\langle \_, t \rangle}^*$
$v_t^*$	$=$	$\{v^* \mid t\}$ otherwise

Figure 6: Encoding of terms

**Remark 31** For a Curry-style term  $t$  and a Curry-style program  $p$  of  $F_\omega^C$ ,

1. If  $t \longrightarrow_{F_\omega^C} t'$  then  $u_t^* \longrightarrow_{F_\omega^C} u_{t'}^*$ .
2.  $\{u^* \mid t\} \longrightarrow_{F_\omega^C}^* u_t^*$
3.  $u_t^* \{x \setminus u'^*\} \longrightarrow_{F_\omega^C}^* u \{x \setminus u'\}_{t \setminus \{x \setminus u'^*\}}^*$  and  
 $u^* \{x \setminus u'^*\} \longrightarrow_{F_\omega^C}^* u \{x \setminus u'\}^*$ .

The encoding of terms allows the simulation of reductions:

**Theorem 32 (Simulation of  $\beta$  for terms)**

*If  $u \longrightarrow_{F_\omega} u'$ , then  $u_t^* \longrightarrow_{F_\omega^C}^+ u_{t'}^*$  and  $u^* \longrightarrow_{F_\omega^C}^+ u'^*$ .*

**Proof:** By simultaneous induction on the derivation of the reduction step, using Remark 31.  $\square$

The translation preserves typing:

**Theorem 33 (Preservation of typing for terms)**

1. If  $\Gamma \vdash_{\Sigma}^{F_{\omega}} u : A$ , then there exists a term  $t$  of system  $F_{\omega}^{\mathcal{C}}$  (with type annotations) such that  $\|t\| = u^*$  and  $\Gamma^* \vdash_{\Sigma} t : A$ .
2. If  $\Gamma \vdash_{\Sigma}^{F_{\omega}} u : A$  and  $\Gamma^*, \Delta \vdash_{\Sigma} t : A^{*\perp}$ , then there exists a program  $p$  of system  $F_{\omega}^{\mathcal{C}}$  (with type annotations) such that  $\|p\| = u_{\|t\|}^*$  and  $\Gamma^*, \Delta \vdash_{\Sigma} p \diamond$ .

**Proof:** By induction on derivations, using Theorem 30 for the conversion rule.  $\square$

Since  $F_{\omega}^{\mathcal{C}}$  is classical, we have a proof of the axiom of double negation elimination:

Let  $\perp = \forall \alpha : \star. \alpha$  (in  $F_{\omega}$  and  $F_{\omega}^{\mathcal{C}}$ ) and  $\top = \exists \alpha : \star. \alpha$  (in  $F_{\omega}^{\mathcal{C}}$ ), and let  $\text{DNE} = \forall \alpha : \star. ((\alpha \Rightarrow \perp) \Rightarrow \perp) \Rightarrow \alpha$  in system  $F_{\omega}$ . We have

$\text{DNE}^* = \forall \alpha : \star. ((\alpha^{\perp} \vee \perp) \wedge \top) \vee \alpha$ . Let

$\mathbf{C} = \Lambda \alpha : \star. \lambda x^B y^{\alpha^{\perp}}. \{x \mid \langle \lambda x'^{\alpha} y'^{\top}. \{x' \mid y\}, \langle \alpha^{\perp}, y \rangle \rangle\}$ , where  $B = (\alpha \wedge \top) \vee \perp$ .

We have

$$\vdash \mathbf{C} : \text{DNE}^*$$

Hence, provable propositions of system  $F_{\omega} + \text{DNE}$  become provable propositions of system  $F_{\omega}^{\mathcal{C}}$ :

**Theorem 34 ( $F_{\omega}$  captures  $F_{\omega} + \text{DNE}$ )** For all derivable judgements of the form

$$z : \text{DNE}, \Gamma \vdash_{\Sigma}^{F_{\omega}} u : A$$

there exists a term  $t$  of system  $F_{\omega}^{\mathcal{C}}$  (with type annotations) such that  $\|t\| = u^*$  and we have

$$\Gamma^* \vdash_{\Sigma} t\{z \setminus \mathbf{C}\} : A^*$$

Through the translation  $A \mapsto A^*$ , system  $F_{\omega}^{\mathcal{C}}$  appears as an extension of system  $F_{\omega} + \text{DNE}$ , and hence the consistency of  $F_{\omega}^{\mathcal{C}}$ , proved in section 5.1, implies that of  $F_{\omega} + \text{DNE}$ .

We then set the following conjecture:

**Conjecture 35 ( $F_{\omega}^{\mathcal{C}}$  is a conservative extension of  $F_{\omega} + \text{DNE}$ )**

There exists a mapping  $\mathcal{B}$  of the upper layer of  $F_{\omega}^{\mathcal{C}}$  into that of  $F_{\omega}$  such that:

1. If  $\Sigma \vdash^{F_{\omega}} A : \star$ , then there exist two terms  $u$  and  $u'$  such that  $\vdash_{\Sigma}^{F_{\omega}} u : A \rightarrow \mathcal{B}(A^*)$  and  $\vdash_{\Sigma}^{F_{\omega}} u' : \mathcal{B}(A^*) \rightarrow A$ .
2. If  $\Gamma \vdash_{\Sigma} t : A$  then there exists a term  $u$  of  $F_{\omega}$  such that  $\mathcal{B}(\Gamma), z : \text{DNE} \vdash_{\Sigma} u : \mathcal{B}(A)$ .

As mentioned in section 4, the mapping that forgets the information about duality is obviously not a good candidate to prove this conjecture, but ongoing work is about refining it for that purpose.

## 6 Conclusion

In this paper we have introduced a classical version of system  $F_\omega$ , called  $F_\omega^C$ . Its upper layer is intuitionistic, its lower layer is classical, and both are strongly normalising.

We have adapted Tait and Girard’s reducibility methods for the two strong normalisation results, using orthogonality and, for the lower layer, Barbanera and Berardi’s symmetric candidates.

$F_\omega^C$  thus provides an opportunity to tackle the two variants of the reducibility method, which we do in section 4, proving the conjecture set in [LM06] that orthogonality does not capture the fixpoint completion of the symmetric candidates. It is worth noting that the counter-examples are not specific to  $F_\omega^C$  at all. First, they hold in propositional logic (they do not involve polymorphism or type constructors), and second they could easily be given for other symmetric calculi for classical logic such as the symmetric  $\lambda$ -calculus [BB96], the  $\bar{\lambda}\mu\tilde{\mu}$ -calculus [CH00] or the dual calculus [Wad03], as long as their untyped versions feature some infinite computations related to the  $\lambda$ -term  $\Delta\Delta$ .

This point being made, it is clear that alternative proofs could have been given instead. For the upper layer we could simply have simulated the reduction in the simply-typed  $\lambda$ -calculus, forgetting all the information about duality ( $A$  and  $A^\perp$  would be mapped to the same term) which plays no computational role in this layer.<sup>3</sup>

However, such an encoding, while preserving the notion of computation, loses all information about duality. This has two consequences:

- It cannot be used to establish a reflection between the upper layer of  $F_\omega^C$  and the simply-typed  $\lambda$ -calculus (or the upper layer of  $F_\omega$ ).
- Since it loses all the logical meaning of type constructors, it cannot be used for a type-preserving encoding of  $F_\omega^C$  into e.g.  $F_\omega + \text{DNE}$ , which we need to prove the conservativity conjecture (Conjecture 35 of section 5.2).

Ongoing work is about refining this forgetful mapping by encoding in  $\lambda$ -terms the information about duality, i.e. some notion of “polarity”, in a way that is useful for the above two points.

For the lower layer we could try to adapt to  $F_\omega$  simpler proofs of strong normalisation of symmetric and non-confluent calculi for classical logic, such as those of [DN05a] or [Dou06] which do not involve the fixpoint construction. We do not know whether these proofs break, for a typing system as strong as that of  $F_\omega^C$ . While we have seen that the fixpoint completion is not captured by orthogonality, it would be interesting to see whether these simpler proofs are captured by it (although they are not expressed in the framework of reducibility to which orthogonality pertains).

---

<sup>3</sup>For instance,  $\alpha$  and  $\alpha^\perp$  would be mapped to the same term,  $A \wedge B$  and  $A \vee B$  would both be mapped to  $x_{\wedge\vee} A B$  and  $\forall\alpha : K . B$  and  $\exists\alpha : K . A$  would both be mapped to  $x_{\forall\exists} \lambda\alpha . A$  for two particular variables  $x_{\wedge\vee}$  and  $x_{\forall\exists}$  that are never bound because they represent the logical connectives.
