Milstein’s type schemes for fractional SDEs

Mihai Gradinaru\textsuperscript{1} and Ivan Nourdin\textsuperscript{2}

Résumé. On étudie la vitesse exacte de convergence de certains schémas d’approximation associés à des équations différentielles stochastiques scalaires dirigées par le mouvement brownien fractionnaire $B$. On utilise le comportement asymptotique des variations à poids de $B$, et la limite de l’erreur entre la solution et son approximation est calculée de façon explicite.

Abstract: Weighted power variations of fractional Brownian motion $B$ are used to compute the exact rate of convergence of some approximating schemes associated to one-dimensional stochastic differential equations (SDEs) driven by $B$. The limit of the error between the exact solution and the considered scheme is computed explicitly.

Key words: Fractional Brownian motion - weighted power variations - stochastic differential equation - Milstein’s type scheme - exact rate of convergence.

2000 Mathematics Subject Classification: 60F15, 60G15, 60H05, 60H35.

1 Introduction

Let $B = (B_t)_{t \in [0,1]}$ be a fractional Brownian motion with Hurst index $H \in (0,1)$. That is, $B$ is a centered Gaussian process with covariance function given by

\[ \text{Cov}(B_s, B_t) = \frac{1}{2} (s^{2H} + t^{2H} - |t-s|^{2H}), \quad s, t \in [0,1]. \]

For $H = 1/2$, $B$ is a standard Brownian motion, while for $H \neq 1/2$, it is neither a semimartingale, nor a Markov process. Moreover, it holds, for any $p > 1$:

\[ E|B_t - B_s|^p = c_p|t - s|^{pH}, \quad s, t \in [0,1], \quad \text{with} \quad c_p = E(|G|^p), \quad G \sim \mathcal{N}(0,1), \]

and, consequently, almost all sample paths of $B$ are Hölder continuous of any order $\alpha \in (0,H)$.

The study of stochastic differential equations driven by $B$ has been considered by using several methods. For instance, in \cite{22} one uses fractional calculus of same type as in \cite{25}; in \cite{2} one uses rough paths theory introduced in \cite{11}, and in \cite{19} one uses regularization method used firstly in \cite{23}.

In the present paper, we consider the easiest stochastic differential equation involving fractional Brownian motion, that is

\[ dX_t = \sigma(X_t)dB_t, \quad t \in [0,1], \quad X_0 = x \in \mathbb{R}. \tag{1.1} \]

Here and in the rest of the paper, $\sigma \in C^\infty(\mathbb{R})$ stands for a real function which is bounded with bounded derivatives. Let us denote by $\phi : \mathbb{R}^2 \rightarrow \mathbb{R}$ the flow associated to $\sigma$, that is the unique solution to

\[ \phi(x, y) = x + \int_0^y \sigma(\phi(x, z))dz, \quad x, y \in \mathbb{R}. \tag{1.2} \]

Assume that the integral with respect to $B$ we consider in (1.1) verifies the following Itô-Stratonovich type formula:

$$f(B_t) = f(0) + \int_0^t f'(B_s) dB_s, \quad t \in [0, 1], \quad f : \mathbb{R} \to \mathbb{R} \text{ smooth enough.}$$

(1.3)

Then, combined with (1.2), one easily checks that

$$X_t^n = \phi(x, B_t), \quad t \in [0, 1],$$

(1.4)

is a solution to (1.1).

Approximating schemes for stochastic differential equations of the type

$$dX_t = \sigma(X_t) dB_t + b(X_t) dt, \quad t \in [0, 1], \quad X_0 = x \in \mathbb{R},$$

(1.5)

have been considered only in few articles. The first work in that direction is [10]. Precisely, whenever $H > 1/2$, it is shown that the Euler approximation of equation (1.5) — but in the particular case where $\sigma(X_t)$ is replaced by $\sigma(t)$, that is the so-called additive case — converges uniformly in probability. In [13] one introduces (see also [24]) some approximating schemes for the analogue of (1.5) where $B$ is replaced by any Hölder continuous function. One determines upper error bounds and, in particular, these results apply almost surely when the driving Hölder continuous function is a single path of the fractional Brownian motion $B$, and this for any Hurst index $H \in (0, 1)$. In [12], upper error bounds for Euler approximations of solutions of (1.3) are derived whenever $H$ is bigger than $1/2$. The convergence of Euler schemes has also been studied in [3] in the context of the rough paths theory.

Results on lower error bounds are available only since very recently: see [13] for the additive case, and [13] for equation (1.5) (see also [14] where approximation methods with respect to a mean square error are analysed). More precisely, it is proved in [15] that the Euler scheme $\hat{X} = \{\hat{X}^{(n)}\}_{n \in \mathbb{N}}$ associated to (1.3) verifies, under some classical assumptions on $\sigma$ and $b$ and whenever $H \in (1/2, 1)$, that

$$n^{2H-1} \left[ \hat{X}^{(n)}_1 - X_1 \right] \overset{a.s.}{\to} \frac{1}{2} \int_0^1 \sigma'(X_s) D_s X_1 ds, \quad n \to \infty.$$  

(1.6)

Here, $D_s X_1$ denotes the Malliavin derivatives of $X_1$ with respect to $B$. Observe that the upper and lower error bounds are obtained from an almost sure convergence, which is somewhat surprising when compared with the case $H = 1/2$, see below. In [13], it is proved that, for the so-called Crank-Nicholson scheme $\mathbf{X} = \{\mathbf{X}^{(n)}\}_{n \in \mathbb{N}}$ associated to (1.1), and defined by

$$\begin{cases}
\mathbf{X}^{(n)}_0 = x, \\
\mathbf{X}^{(n)}_{(\ell+1)/n} = \mathbf{X}^{(n)}_{\ell/n} + \frac{1}{2} \left( \sigma(\mathbf{X}^{(n)}_{\ell/n}) + \sigma(\mathbf{X}^{(n)}_{(\ell+1)/n}) \right) (B_{(\ell+1)/n} - B_{\ell/n}), \quad \ell \in \{0, \ldots, n-1\},
\end{cases}$$

(1.7)

the following convergence holds for $\sigma$ regular enough and whenever $H \in (1/3, 1/2)$:

$$n^{\alpha} \left[ \mathbf{X}^{(n)}_1 - X_1 \right] \overset{\text{Prob}}{\to} 0, \quad \forall \alpha < 3H - 1/2, \quad n \to \infty.$$  

(1.8)

In the particular case where the diffusion coefficient $\sigma$ verifies $\sigma(x)^2 = \alpha x^2 + \beta x + \gamma$, for some $\alpha, \beta, \gamma \in \mathbb{R}$, one can derive the exact rate of convergence and one proves that, as $n \to \infty$:

$$n^{3H-1/2} \left[ \mathbf{X}^{(n)}_1 - X_1 \right] \overset{\text{Law}}{\to} \frac{\alpha}{12} \sigma(X_1) G.$$  

(1.9)
Here, $G$ is a centered Gaussian random variable independent of $X_1$, whose variance depends uniquely on $H$. In particular, the upper and lower error bounds are obtained here from a convergence in law.

As we said, the convergence in (1.6) is somewhat surprising, since there is no analogue for the case of the standard Brownian motion. More precisely, when $H = 1/2$, it is proved in [8] that the Euler scheme (1.6) verifies (by denoting $X$ the case of the standard Brownian motion. More precisely, when convergence in law.

Here, $W$ is a Brownian motion independent of the Brownian motion $B$ uniquely on $\mathbb{N}$.

On the other hand, it can be proved (see Remark 4.2.2) that, for the Crank-Nicholson scheme (1.5), we have, as $n \to \infty$:

$$n \left[ \hat{X}_1^{(n)} - X_1^{\text{Str}} \right] \xrightarrow{\text{Law}} \frac{1}{\sqrt{2}} Y_1 \int_0^1 \sigma(X_1^{\text{Str}}) \sigma'(X_1^{\text{Str}}) Y_s^{-1} dW_s, \quad n \to \infty. \quad (1.10)$$

where $X_1^{\text{Str}}$ denotes the solution of (1.4) in the Stratonovich sense.

In the present paper, we are interested in a better understanding of the phenomenon observed in (1.7), (1.9), (1.10) or (1.11). What type of convergence allows to derive the upper and lower error bounds for some natural scheme of Milstein’s type? More precisely, let us define, by induction, the family of differential operators $(\mathcal{D}_j)_{j \in \mathbb{N} \cup \{0\}}$ as

$$\mathcal{D}^0 f = f, \quad \mathcal{D}^1 f = f' \sigma \quad \text{and, for } j \geq 2, \quad \mathcal{D}^j f = \mathcal{D}^1(\mathcal{D}^{j-1} f). \quad (1.12)$$

For instance, the first $\mathcal{D}^j \sigma$’s are given by:

$$\mathcal{D}^0 \sigma = \sigma, \quad \mathcal{D}^1 \sigma = \sigma \sigma', \quad \mathcal{D}^2 \sigma = \sigma \sigma' + \sigma^2 \sigma'', \quad \mathcal{D}^3 \sigma = \sigma \sigma' + 4 \sigma^2 \sigma' + 6 \sigma^3 \sigma'' \quad \text{etc.}$$

Now, let us consider the following scheme introduced in [8]:

$$\begin{align*}
\{ \hat{X}_1^{(n)} \}_{n \in \mathbb{N}} & \text{ converge? Is the limit } X_1 \text{ given by (1.4), as could be reasonably expected? What is the rate of convergence? Are upper and lower error bounds obtained from a convergence in law or rather from a pathwise type convergence?}
\end{align*}$$

The aim of the present paper is to answer the following questions. Does the sequence $(\hat{X}_1^{(n)})_{n \in \mathbb{N}}$ converge? Is the limit $X_1^\dagger$ given by (1.4), as could be reasonably expected? What is the rate of convergence? Are upper and lower error bounds obtained from a convergence in law or rather from a pathwise type convergence?

The paper is organized as follows: the next section reviews some very recent results concerning the asymptotic behavior of weighted power variations of fractional Brownian motion. In section 3, after recalling the definition and the main properties of the so-called Newton-Cotes integral, we explain how to use it in order to study (1.1). Finally, in section 4, we state and prove our results concerning the exact rate of convergence associated to (1.13).
2 Asymptotic behavior of weighted power variations

Let $\kappa \geq 2$ be an integer, and $h, g : \mathbb{R} \to \mathbb{R}$ be two functions belonging to $C^\infty$. Assume moreover that $h$ and $g$ are bounded with bounded derivatives. Denote by $\mu_{2n}$ the $2n$-moment of a random variable $G \sim \mathcal{N}(0, 1)$. The following theorem collects some very recent results about the asymptotic behavior of the so-called weighted power variations of $B$, defined by

$$\sum_{\ell=0}^{n-1} h(B_{\ell/n})(\Delta B_{\ell/n})^\kappa$$

(recall that $\Delta B_{\ell/n}$ stands for $B_{(\ell+1)/n} - B_{\ell/n}$).

**Theorem 2.1**

1. If $\kappa$ is even and $H \in (0, 1)$ then, as $n \to \infty$:

$$n^{\kappa H - 1} \sum_{\ell=0}^{n-1} h(B_{\ell/n})(\Delta B_{\ell/n})^\kappa \xrightarrow{\text{Prob}} \mu_{2n} \int_0^1 h(B_s)ds.$$  \hspace{1cm} (2.1)

2. If $\kappa$ is odd and $H \in (0, 1/2)$ then, as $n \to \infty$:

$$n^{(\kappa + 1)H - 1} \sum_{\ell=0}^{n-1} h(B_{\ell/n})(\Delta B_{\ell/n})^\kappa \xrightarrow{\text{Prob}} - \frac{\mu_{2n+1}}{2} \int_0^1 h'(B_s)ds.$$  \hspace{1cm} (2.2)

3. If $\kappa$ is odd and $H = 1/2$ then, as $n \to \infty$,

$$\left( B_1, n^{\frac{\kappa - 1}{2}} \sum_{\ell=0}^{n-1} g(B_{\ell/n})(\Delta B_{\ell/n})^\kappa, n^{\frac{\kappa - 1}{2}} \sum_{\ell=0}^{n-1} h(B_{\ell/n})(\Delta B_{\ell/n})^{\kappa + 1} \right)$$

$$\xrightarrow{\text{Law}} \left( B_1, \int_0^1 g(B_s)(\sqrt{\mu_{2n}}dW_s + \mu_{2n+1}dB_s), \mu_{2n+1} \int_0^1 h(B_s)ds \right),$$  \hspace{1cm} (2.3)

with $W$ another standard Brownian motion independent of $B$.

4. If $\kappa$ is odd and $H \in (1/2, 1)$ then, as $n \to \infty$:

$$n^{(\kappa - 1)H} \sum_{\ell=0}^{n-1} h(B_{\ell/n})(\Delta B_{\ell/n})^\kappa \xrightarrow{\text{Prob}} \mu_{2n+1} \int_0^{B_1} h(x)ds.$$  \hspace{1cm} (2.4)

**Remark 2.2**

1. For sake of conciseness, we omit the proof of Theorem 2.1. We give below some ideas and references for the proofs.

2. The convergence (2.1) is actually almost sure. Its proof is a classical result when $h \equiv 1$ (see e.g. [7] when $\kappa = 2$). If $h$ is arbitrary, the proof could be completed along the lines of the proof of Lemma 3.1, p. 7-8 in [4].

3. Proofs of (2.2) and (2.4) can be completed along the lines of [17, Corollary 2].

4. We shall see that, for the standard Brownian motion case, in order to study our Milstein’s type schemes one needs the behaviour of the triplet (2.3) and not only the behaviour of the second coordinate in (2.3). The proof of (2.3) can be completed along
the lines of [20, Corollary 2.9]. More precisely, using the methodology introduced in this latter reference, we first prove that\footnote{Using the notion of \textit{stable convergence} for random variables, \cite{20} is equivalent to say that}
\[
n^{rac{κ}{2}} \sum_{ℓ=0}^{n-1} g(B_{t_{ℓ/n}})(ΔB_{t_{ℓ/n}})^κ \xrightarrow{\text{Law}} \left( (B_t)_{t \in [0,1]}, \int_0^1 g(B_s)(\sqrt{μ_κ}dW_s + μ_{κ+1}dB_s) \right).
\]

Then, using the fact that (see (2.1)), as as \(n \to ∞\),
\[
n^{rac{κ−1}{2}} \sum_{ℓ=0}^{n-1} h(B_{t_{ℓ/n}})(ΔB_{t_{ℓ/n}})^κ \xrightarrow{\text{Prob}} \int_0^1 h(B_s)ds,
\]
and that \(μ_{κ+1} \int_0^1 h(B_s)ds\) is a random variable measurable with respect to \(B\), the desired conclusion follows easily.

5. Other results on weighted variations of fractional Brownian motion (or related processes)
can be found in [1] and [9].

3 Newton-Cotes integral and fractional SDEs

In the sequel, we will use, as integral with respect to \(B\), the so-called Newton-Cotes integral introduced in \cite{5} and studied further in [19].

**Definition 3.1** Let \(f : \mathbb{R} \to \mathbb{R}\) be a continuous function, \(X, Y\) be two continuous processes on \([0,1]\) and \(N \in \mathbb{N} \cup \{0\}\). The \(N\)-order Newton-Cotes integral of \(f(Y)\) with respect to \(X\) is defined by:
\[
\int_0^t f(Y_s)d^{NC,N}X_s := \lim_{ε \to 0} \frac{1}{ε} \int_0^t ds(X_{s+ε} - X_s) \int_0^1 f(Y_s + α(Y_{s+ε} - Y_s))ν_N(αdα), \ t \in [0,1],
\]
provided the limit exists. Here \(ν_0 = \delta_0, ν_1 = (δ_0 + δ_1)/2\) and, for \(N ≥ 2\),
\[
ν_N = \sum_{j=0}^{2N-2} \left( \int_0^1 \prod_{k \neq j} \frac{2(N-1)u - k}{j - k} \, du \right) δ_{j/(2N-2)},
\]
\(δ_a\) being the Dirac measure at point \(a\).

**Remark 3.2** 1. The 0- and 1-order Newton-Cotes integrals are nothing but the forward integral and the symmetric integral in the sense of Russo-Vallois \cite{23}, respectively:
\[
\int_0^t f(Y_s)d^{NC,0}X_s = \int_0^t f(Y_s)dX_s = \lim_{ε \to 0} \frac{1}{ε} \int_0^t f(Y_s)(X_{s+ε} - X_s)ds,
\]
\[
\int_0^t f(Y_s)d^{-}X_s = \left( \int_0^t f(Y_s) \right) \left( \int_0^1 \frac{1}{ε} \int_0^ε f(Y_s)(X_{s+ε} - X_s)ds \right)ds,
\]

\text{Here,} \(F_B\) \text{denotes the} \(\sigma\)-field generated by \((B_t)_{t \in [0,1]}\) (see also Theorem 1.1, p. 3 in [3]).
and
\[ \int_0^t f(Y_s)d^{NC,1}_sX_s = \int_0^t f(Y_s)d^r X_s = \lim_{\varepsilon \to 0} \frac{1}{\varepsilon} \int_0^t \frac{f(Y_{s+\varepsilon}) + f(Y_s)}{2} (X_{s+\varepsilon} - X_s)ds. \]

2. Another way to define \( \nu_N \) is to view it as the unique discrete signed probability carried by \( j/(2N-2) \) \( (j = 0, \ldots, 2N - 2) \), which coincides with Lebesgue measure on polynomials of degree smaller than \( 2N - 1 \).

The Newton-Cotes integral defined by (3.1) is actually a special case of so-called \( N \)-order \( \nu \)-integrals introduced in [5], p. 789. Moreover, in the same cited paper, p. 795, one proves that the \( N \)-order Newton-Cotes integral of \( f(B_t) \) with respect to \( B_t \) exists for any \( f \in C^{4N+1} \) if and only if \( H \in (1/(4n+2), 1) \). In this case, an Itô’s type change of variables formula holds: for any antiderivative \( F \) of \( f \), we can write
\[ F(B_t) - F(0) = \int_0^t f(B_s)d^{NC,N}_sB_s, \quad t \in [0, 1]. \] (3.2)

Moreover, as a consequence of (3.2), let us note that
\[ \int_0^t f(B_s)d^{NC,N}_sB_s = \int_0^t f(B_s)d^{NC,n}_sB_s = F(B_t) - F(0), \]
as soon as \( f \in C^{4N+1} \), \( n < N \) and \( H \in (1/(4n+2), 1) \). Therefore, for \( f \) regular enough, it is possible to define the Newton-Cotes integral without ambiguity by:
\[ \int_0^t f(B_s)d^{NC,n}_sB_s := \int_0^t f(B_s)d^{NC,N}_sB_s \quad \text{if} \quad H \in (1/(4n+2), 1). \] (3.3)

Set \( n_H := \inf \{ n \geq 1 : H > 1/(4n+2) \} \). Hence, an immediate consequence of (3.2) and (3.3) is that, for any \( H \in (0, 1) \) and any \( f : \mathbb{R} \to \mathbb{R} \) of class \( C^{4n+1} \), the following Itô’s type change of variables formula holds:
\[ F(B_t) = F(0) + \int_0^t f(B_s)d^{NC}_sB_s, \quad \text{for any antiderivative} \ F \ \text{of} \ f. \] (3.4)

**Remark 3.3** In the sequel we will only use the fact that the Newton-Cotes integral verifies the classical change of variable formula ([3.2] or [3.3]). Consequently, any other stochastic integral verifying (3.4) could be used in the following.

All along this paper we will work with an ellipticity assumption, and we will also need regularity for the function \( \sigma \). More precisely, we suppose
\[ (\sigma) \quad \inf_{\mathbb{R}} |\sigma| > 0 \quad \text{and} \quad \sigma \in C^\infty(\mathbb{R}) \ \text{is bounded with bounded derivatives}. \]

Under hypothesis \((\sigma)\), the flow \( \phi \) associated to \( \sigma \), given by (1.2), is well-defined and verifies the group property:
\[ \forall x, y, z \in \mathbb{R}, \quad \phi(\phi(x, y), z) = \phi(x, y + z). \] (3.5)

Note that the process \( X^x \) given by (1.4) verifies:
\[ X^x_t = x + \int_0^t \sigma(X^x_s)d^{NC}_sB_s, \quad t \in [0, 1], \] (3.6)
as we can see immediately, by applying (3.4).
Remark 3.4 In [21] (see also [20]), one studies a notion of solution for (2.6) and also the existence and the uniqueness of solution. Note however that, in the present work, we will only use the fact that there exists a natural solution to (3.6) given by (1.4).

The following result explains the definition (1.13). By using (1.12), the process $X^x$ defined by (1.4) can be expanded as follows:

**Lemma 3.5** For any integers $m \geq 0$, $n \geq 1$ and $\ell \in \{0, \ldots, n-1\}$, we have

$$
X_{\ell+1/n}^x = X_{\ell/n}^x + \sum_{j=0}^{m} \frac{1}{(j+1)!} \mathcal{D}^j \sigma(X_{\ell/n}^x) (\Delta B_{\ell/n})^{j+1}
$$

$$
+ \int_{\ell/n}^{(\ell+1)/n} d^{NC} B_{t_1} \int_{\ell/n}^{t_1} d^{NC} B_{t_2} \ldots \int_{\ell/n}^{t_m} d^{NC} B_{t_{m+1}} \int_{\ell/n}^{t_{m+1}} d^{NC} B_{t_{m+2}} \mathcal{D}^{m+1} \sigma(X_{\ell+2/m}^x) d^{NC} B_{t_{m+2}}.
$$

(3.7)

**Proof.** We proceed by induction on $m$. By applying (3.6), and then using (1.4) and (3.4), we can write:

$$
X_{\ell+1/n}^x = X_{\ell/n}^x + \sigma(X_{\ell/n}^x) \Delta B_{\ell/n} + \int_{\ell/n}^{(\ell+1)/n} (\sigma(X_{t_1}^x) - \sigma(X_{\ell/n}^x)) d^{NC} B_{t_1}
$$

$$
= X_{\ell/n}^x + \sigma(X_{\ell/n}^x) \Delta B_{\ell/n} + \int_{\ell/n}^{(\ell+1)/n} d^{NC} B_{t_1} \int_{\ell/n}^{t_1} \sigma'(X_{t_2}^x) d^{NC} B_{t_2},
$$

which is exactly (3.7) for $m = 0$.

Now, let us assume that (3.7) is true for some $m \in \mathbb{N} \cup \{0\}$. Then we can write

$$
X_{\ell+1/n}^x = X_{\ell/n}^x + \sum_{j=0}^{m} \frac{1}{(j+1)!} \mathcal{D}^j \sigma(X_{\ell/n}^x) (\Delta B_{\ell/n})^{j+1}
$$

$$
+ \mathcal{D}^{m+1} \sigma(X_{\ell/n}^x) \int_{\ell/n}^{(\ell+1)/n} d^{NC} B_{t_1} \int_{\ell/n}^{t_1} d^{NC} B_{t_{m+1}} \int_{\ell/n}^{t_{m+1}} d^{NC} B_{t_{m+2}} + \int_{\ell/n}^{(\ell+1)/n} d^{NC} B_{t_1} \int_{\ell/n}^{t_1} d^{NC} B_{t_{m+1}} \int_{\ell/n}^{t_{m+1}} (\mathcal{D}^{m+1} \sigma(X_{\ell+2/m}^x) - \mathcal{D}^{m+1} \sigma(X_{\ell/n}^x)) d^{NC} B_{t_{m+2}}.
$$

(3.8)

On one hand, using (3.4) repeatedly, it is immediate to compute that

$$
\int_{\ell/n}^{(\ell+1)/n} d^{NC} B_{t_1} \int_{\ell/n}^{t_1} d^{NC} B_{t_{m+1}} \int_{\ell/n}^{t_{m+1}} d^{NC} B_{t_{m+2}} = \frac{1}{(m+2)!} (\Delta B_{\ell/n})^{m+2}.
$$

On the other hand, using (1.4) and again (3.4), we can write

$$
\mathcal{D}^{m+1} \sigma(X_{\ell+2/m}^x) - \mathcal{D}^{m+1} \sigma(X_{\ell/n}^x) = \int_{\ell/n}^{t_{m+2}} \sigma(\mathcal{D}^{m+1} \sigma)(X_{\ell+3/m}^x) d^{NC} B_{t_{m+3}}.
$$

Finally, putting these latter two equalities in (3.8) and noting that $\sigma(\mathcal{D}^{m+1} \sigma)' = \mathcal{D}^{m+2} \sigma$ by definition, we obtain that (3.7) is true for $m+1$. The proof by induction is done. \(\square\)

Clearly, (1.13) is the natural scheme constructed from (3.3), by considering the $(m+2)$th multiple integral in the right hand side of (3.3) as a remainder.
4 Rate of convergence of the approximating schemes

4.1 Statement of the main result

Recall that we denote by \( \mu_2 \) the 2-moment of a random variable \( G \sim \mathcal{N}(0,1) \). For \( m \in \mathbb{N} \cup \{0\} \), let us introduce the functions \( g_m, h_m : \mathbb{R} \rightarrow \mathbb{R} \) given by:

\[
g_m = -\sigma' h_m + h_{m+1} \quad \text{and} \quad h_m = -\frac{(\varphi^{m+1}\sigma)/\sigma}{(m+2)!}.
\]

Our main result contains a complete answer to the questions in the introduction and can be stated as follows:

**Theorem 4.1** Assume that hypothesis \((\mathcal{E})\) is in order, and let \( m \in \mathbb{N} \cup \{0\} \). Then, for any \( H \in \left(1/(m+2), 1\right) \), the sequence \( \{\tilde{X}^{(n)}_1\}_{n \in \mathbb{N}} \) defined by (1.13) converges almost surely toward \( X_x^1 = \phi(x,B_1) \) as \( n \rightarrow \infty \). Moreover,

- when \( m \) is even and \( H \in \left(1/(m+2), 1\right) \),
  \[
n^{(m+2)H-1} \left[ \tilde{X}^{(n)}_1 - X^1_x \right] \xrightarrow{\text{Prob}} \mu_{m+2} \sigma(X_1^x) \int_0^1 h_m(X_s^x)ds;
  \]

- when \( m \) is odd and \( H \in \left(1/(m+2), 1/2\right) \),
  \[
n^{(m+3)H-1} \left[ \tilde{X}^{(n)}_1 - X^1_x \right] \xrightarrow{\text{Prob}} \mu_{m+3} \sigma(X_1^x) \int_0^1 \left(g_m - \frac{1}{2}\sigma h'_m\right)(X_s^x)ds;
  \]

- when \( m \) is odd and \( H = 1/2 \),
  \[
n^{(m+1)/2} \left[ \tilde{X}^{(n)}_1 - X^1_x \right] \xrightarrow{\text{Law}} \sigma(X_1^x) \left(\int_0^1 h_m(X_s^x)\left[\sqrt{\mu_{2m+4}}dW_s + \mu_{m+3}dB_s\right] + \mu_{m+3} \int_0^1 g_m(X_s^x)ds\right),
  \]

  with \( W \) a Brownian motion independent of \( B \).

- when \( m \) is odd and \( H \in (1/2, 1) \),
  \[
n^{(m+1)H} \left[ \tilde{X}^{(n)}_1 - X^1_x \right] \xrightarrow{\text{Prob}} \mu_{m+3} \sigma(X_1^x) \int_0^{B_1} h_m(\phi(x,y))dy.
  \]

**Remark 4.2**

1. For \( m = 0 \) and \( H > 1/2 \), one recovers the convergence \( (4.1) \).

2. With the same method used to obtain \( (4.4) \), one could prove \( (1.11) \) with the help of Lemma 3.4 in \( [19] \). Details are left to the reader.

3. Actually, we could prove that the convergence is almost sure in \( (4.2) \). Also the convergence in \( (4.3) \) is certainly almost sure, but the method of proof we have used here does not allow to deduce it. Thus it remains an open question.

4. According to Theorem 4.1, whenever \( H \in (1/(m+2), 1/2) \) the scheme \( \tilde{X} \) of size \( m = 2\kappa - 1 \) has the same rate of convergence than the scheme \( \hat{X} \) of size \( m = 2\kappa \), namely \( n^{(2\kappa+2)H-1} \). Thus, it is a priori better to use odd-size schemes.
5. With the same method (see also Theorems 2 and 4 in [13]), one could also derive the exact rate of convergence for the global error on the whole interval [0, 1].

Observe that, under \( (\xi) \), the convergences \([\text{R}3]\) and \([\text{R}4]\) give the right lower error bound if the probability that the right-hand side vanishes is strictly less than 1. Due to \([\text{I}4]\) and the fact that \(B_t\) has a Gaussian density for any \( t \in [0, 1] \), it is easy to see that this last fact is equivalent to have that the real function inside the integral, say \( f_m \), is not identically zero.

Indeed, if \( \int_0^1 g(B_s)ds = 0 \) almost surely for a certain \( g \in C^4_b(\mathbb{R}) \), then \( 0 = D_u \int_0^1 g(B_s)ds = \int_u^1 g'(B_s)ds \), for any \( u \in [0, 1] \) (here \( D \) denotes the Malliavin derivative with respect to \( B \)). We deduce that \( g'(B_u) = 0 \), for any \( u \in [0, 1] \), and, since the support of the law of \( B_1 \) (for instance) is \( \mathbb{R} \), we obtain \( g' = 0 \). The desired conclusion follows easily.

Except for \( m = 0 \), solving \( f_m = 0 \) seems complicated. Nevertheless, when \( m = 1 \), we can state:

**Proposition 4.3** Assume that \( (\xi) \) is in order, and moreover that \( \sigma \) does not vanish. Then the function \( 3\sigma^3 + 6\sigma'\sigma'' + \sigma^2\sigma''' \) (which is, up to a constant, the function appearing inside the integral of the right-hand side of \([\text{I}3]\) when \( m = 1 \)) is not identically zero.

**Remark 4.4**

1. When \( \sigma(x) = \sigma \) is constant, we have \( \hat{X}^{(m)}_t = X^x_t = x + \sigma B_t \). Consequently, the study of the rate of convergence in the case where \( \sigma \) is a constant function is not interesting.

2. A corollary of Theorem \([\text{I}1]\) and Proposition \([\text{I}3]\) is that, under the additional hypothesis that \( \sigma' \) does not vanish, the upper and lower error bounds always come from a convergence in probability whenever \( H \neq 1/2 \) and \( m = 1 \). In particular, we never observe a phenomenon of the type \([\text{I}3]\).

**Proof of Proposition 4.3** Since \( \sigma' \) does not vanish, we have either \( \sigma' > 0 \) or \( \sigma' < 0 \). Suppose for instance that \( \sigma' > 0 \), the proof for the other situation being similar. Assume for a moment that \( f := 3\sigma^3 + 6\sigma'\sigma'' + \sigma^2\sigma''' \) is identically zero. We then have \( 3\sigma^3(\sigma^2)'' = -\sigma(\sigma^2)''' \).

We deduce that the derivative of \( \sigma^3(\sigma^2)'' \) is zero and then \( (\sigma^2)'' = \alpha \sigma^{-3} \) on \( \mathbb{R} \), for some \( \alpha \neq 0 \). Set \( h = \sigma^2 \); we have \( h'' h' = \alpha h' h^{-3/2} \) or, equivalently, \( h'' = -4\alpha h^{-3/2} + \beta \) for some \( \beta \in \mathbb{R} \). In particular, we have \( \beta - 4\alpha y^{-1/2} > 0 \), for any \( y \in h(\mathbb{R}) \). Let \( F \) be defined on \( h(\mathbb{R}) \) by

\[
F(y) = \int_y^9 \frac{dz}{\sqrt{\beta - 4\alpha z^{-1/2}}}
\]

For all \( x \in \mathbb{R} \), we have

\[
F(\sigma(x)^2) = F(h(x)) = x + \gamma, \text{ for some } \gamma \in \mathbb{R}.
\]  

The function \( \sigma^2 \) being bounded, we necessarily have \( h(x) \to (4\alpha/\beta)^2 \) (in particular \( \beta \neq 0 \)) as \( x \to \infty \). Then, since \( h'' = \alpha h^{-3/2} \), this implies that \( h''(x) \to \beta^3/(4\alpha^2) \) as \( x \to \infty \), which is in contradiction with the fact that \( h = \sigma^2 \) is bounded. The proof of the proposition is done. \( \Box \)

### 4.2 Proof of Theorem 4.1

Here, and for the rest of the paper, we assume that \( H \) belongs to \((1/(m+2), 1)\) and we denote \( \Delta_n = \max_{k=0,...,n-1} |\Delta B_{k/n}| \). We split the proof of Theorem 4.1 into several steps.
1. General computations. The following lemma can be shown by using the same method as in the proof of Lemma 3.3, but with Lebesgue integral instead of Newton-Cotes integral (and by taking into account that $\sigma \in C^\infty(\mathbb{R})$ is bounded with bounded derivatives, in order to have uniform estimates):

**Lemma 4.5** As $y \to 0$, we have, uniformly in $x \in \mathbb{R}$,

$$\phi(x, y) = x + \sum_{j=0}^{m+2} \frac{1}{(j+1)!} \partial^j \sigma(x) y^{j+1} + O(y^{m+4}).$$

By applying this lemma to $x = \hat{X}^{(n)}_{k/n}$ and $y = \Delta B_{k/n}$, we obtain, using the definition of $\hat{X}^{(n)}_{(k+1)/n}$,

$$\hat{X}^{(n)}_{(k+1)/n} = \phi(\hat{X}^{(n)}_{k/n}, \Delta B_{k/n}) - \mathcal{O}^{m+1} \sigma(\hat{X}^{(n)}_{k/n}) \frac{(\Delta B_{k/n})^{m+2}}{(m+2)!}$$

By straightforward computations we get²

$$\hat{X}^{(n)}_{(k+1)/n} = \phi \left( \hat{X}^{(n)}_{k/n}, \Delta B_{k/n} + h_m(\hat{X}^{(n)}_{k/n}) (\Delta B_{k/n})^{m+2} + g_m(\hat{X}^{(n)}_{k/n}) (\Delta B_{k/n})^{m+3} + O(\Delta_n^{m+4}) \right).$$

(4.7)

with $g_m$ and $h_m$ given by (4.11). By applying the group property (3.4) repeatedly, we finally obtain that, for any $\ell \in \{1, \ldots, n\}$:

$$\hat{X}^{(n)}_{\ell/n} = \phi \left( x, B_{\ell/n} + \sum_{k=0}^{\ell-1} h_m(\hat{X}^{(n)}_{k/n}) (\Delta B_{k/n})^{m+2} + \sum_{k=0}^{\ell-1} g_m(\hat{X}^{(n)}_{k/n}) (\Delta B_{k/n})^{m+3} + O(n\Delta_n^{m+4}) \right).$$

(4.8)

Since $\partial \phi/\partial y = \sigma \circ \phi$ is bounded and (δ) is in order, we deduce, as $n \to \infty$,

$$\sup_{\ell \in \{1, \ldots, n\}} \left| \hat{X}^{(n)}_{\ell/n} - X^{x}_{\ell/n} \right| = \sup_{\ell \in \{1, \ldots, n\}} \left| \hat{X}^{(n)}_{\ell/n} - \phi(x, B_{\ell/n}) \right| = O(n\Delta_n^{m+2}).$$

(4.9)

In particular, $\hat{X}^{(n)}_1$ converges almost surely to $X^x_1$ as $n \to \infty$, since $H > 1/(m+2)$.

2. Proof of (4.3). Let $m$ be an even integer. As a consequence of (4.8) and (1.3), we can write

$$\hat{X}^{(n)}_1 = \phi \left( x, B_1 + \sum_{k=0}^{n-1} h_m(X^{x}_{k/n}) (\Delta B_{k/n})^{m+2} + O(n\Delta_n^{m+3}) + O(n^2\Delta_n^{2m+4}) \right).$$

(4.10)²

In fact, we rather obtain

$$\hat{X}^{(n)}_{(k+1)/n} = \phi \left( \hat{X}^{(n)}_{k/n}, \Delta B_{k/n} + h_m(\hat{X}^{(n)}_{k/n}) (\Delta B_{k/n})^{m+2} + g_m(\hat{X}^{(n)}_{k/n}) (\Delta B_{k/n})^{m+3} \right) + O(\Delta_n^{m+4}),$$

which is not exactly (4.7). But, in order to introduce $O(\Delta_n^{m+4}(B))$ in the argument of $\phi$, we proceed as follows, by using the ellipticity property in hypothesis (δ):

$$\phi(x, z) + O(\delta) = \phi(x, \phi^{-1}(x, \phi(x, z) + O(\delta))) = \phi(x, z + O(\delta)).$$

10
Due to (2.2) with \( \kappa = m + 2 \), and due to the fact that \( X^x_f = \phi(x, B_t) \) and \( \partial \phi / \partial y = \sigma \circ \phi \), we finally obtain (4.2).

3. **Proof of (4.3) for** \( H \in (2/(2m+3), 1/2) \). **Let** \( m \) be an odd integer and assume that \( H \in (2/(2m+3), 1/2) \). Thanks to (4.3), identity (4.8) can be transformed into

\[
\hat{X}^{(n)}_{k/n} = \phi \left( x, B_{k/n} + \sum_{j=0}^{\ell-1} \frac{1}{j!} \frac{\partial^j \phi}{\partial y^j} (x, B_{k/n}) \left( \sum_{k_1=0}^{k-1} h_m(\hat{X}^{(n)}_{k_1/n})(\Delta B_{k_1/n})^{m+2} + O(n\Delta_{n}^{m+3}) \right) \right) + O(n^{M+1} \Delta_{n}^{(m+2)(M+1)}). \tag{4.11}
\]

On the other hand, due to (4'), we have, for any fixed \( M \geq 1 \) and uniformly in \( x \in \mathbb{R} \),

\[
\phi(x, y) = \phi(x, y_1) + \sum_{j=1}^{M} \frac{1}{j!} \frac{\partial^j \phi}{\partial y^j} (x, y_1)(y_2 - y_1)^j + O((y_2 - y_1)^{M+1}).
\]

Combined with (4.3), it yields

\[
\hat{X}^{(n)}_{k/n} = x_{k/n} + \sum_{j=1}^{M} \frac{1}{j!} \frac{\partial^j \phi}{\partial y^j} (x, B_{k/n}) \left( \sum_{k_1=0}^{k-1} h_m(\hat{X}^{(n)}_{k_1/n})(\Delta B_{k_1/n})^{m+2} + O(n\Delta_{n}^{m+3}) \right) \right) + O(n^{M+1} \Delta_{n}^{(m+2)(M+1)}). \tag{4.12}
\]

By using (4.12) with \( M = 1 \) as well as the equality \( \partial \phi / \partial y = \sigma \circ \phi \), we get

\[
\hat{X}^{(n)}_{k/n} = x_{k/n} + \sigma(X_{k/n}) \left( \sum_{k_1=0}^{k-1} h_m(\hat{X}^{(n)}_{k_1/n})(\Delta B_{k_1/n})^{m+2} + O(n^2 \Delta_{n}^{2m+4}) + O(n\Delta_{n}^{m+3}) \right)
\]

and then, by (4.9),

\[
\hat{X}^{(n)}_{k/n} = x_{k/n} + \sigma(X_{k/n}) \left( \sum_{k_1=0}^{k-1} h_m(\hat{X}^{(n)}_{k_1/n})(\Delta B_{k_1/n})^{m+2} + O(n^2 \Delta_{n}^{2m+4}) + O(n\Delta_{n}^{m+3}) \right)
\]

By inserting the previous equality in (4.11) with \( \ell = n \), we obtain

\[
\hat{X}^1_f = \phi(x, B_1) + \sum_{k=0}^{n-1} h_m(X_{k/n})(\Delta B_{k/n})^{m+2} + \sum_{k=0}^{n-1} g_m(X_{k/n})(\Delta B_{k/n})^{m+3}
\]

\[
+ \sum_{k=0}^{n-1} \sigma h_m'(X_{k/n})(\Delta B_{k/n})^{m+2} \sum_{j=0}^{k-1} h_m(X_{j/n})(\Delta B_{j/n})^{m+2}
\]

\[
+ O(n^2 \Delta_{n}^{3m+6}) + O(n^2 \Delta_{n}^{2m+5}) + O(n\Delta_{n}^{m+4}) \tag{4.13}
\]

Due to (2.2) with \( \kappa = m + 2 \) we have, as \( n \to \infty \),

\[
n^{(m+3)H-1} \sum_{k=0}^{n-1} h_m(X_{k/n})(\Delta B_{k/n})^{m+2} \xrightarrow{\text{Prob}} - \frac{\mu_{m+3}}{2} \int_0^1 \sigma h_m'(X_s)ds
\]

11
and also, due this time to \( (2.1) \) with \( \kappa = m + 3 \), as \( n \to \infty \),

\[
n^{(m+3)H-1} \sum_{k=0}^{n-1} g_m(X_{i/k}) (\Delta B_{i/k})^{m+3} \to_{\text{Prob}} \mu_{m+3} \int_0^1 g_m(X^x_s) ds.
\]

Moreover, since we assume in this step that \( H > \frac{2}{(2m+3)} \), we have, as \( n \to \infty \),

\[
n^{(m+3)H} \Delta_n^{m+4} \to 0, \quad n^{(m+3)H+1} \Delta_n^{2m+5} \to 0 \quad \text{and} \quad n^{(m+3)H+2} \Delta_n^{3m+6} \to 0.
\]

At this level, we need the following result which is contained in \cite[Proposition 7]{17}:

**Lemma 4.6** Fix an integer \( q \geq 2 \) and denote by \( H_q \) the \( q \)th Hermite polynomial. Let \( f \in C^{2q}(\mathbb{R}) \) be bounded with bounded derivatives and, for \( k \in \{1, \ldots, n\} \), denote

\[
S_k^{(q)}(f) := \sum_{j=0}^{k-1} f(B_{j/n}) H_q(n^H \Delta B_{j/n}).
\]

Then

\[
E|S_k^{(q)}(f)|^2 = O(n^{1/2(2-2HQ)}) \quad \text{as} \quad n \to \infty, \quad \text{uniformly in} \quad k.
\] (4.14)

Recall also that, since \( m+2 \) is odd, the monomial \( x^{m+2} \) may be expanded in terms of the Hermite polynomials as follows:

\[
x^{m+2} - \mu_{m+3} x = \sum_{q=1}^{(m+1)/2} a_{m+2,2q+1} H_{2q+1}(x), \quad \text{for some universal constants} \quad a_{m+2,2q+1}.
\] (4.15)

Therefore, for \( k \in \{1, \ldots, n\} \),

\[
n^{(m+3)H-1} \sum_{j=0}^{k-1} h_m(X_{j/n}^x) (\Delta B_{j/n})^{m+2} - \mu_{m+3} n^{2H-1} \sum_{j=0}^{k-1} h_m(X_{j/n}^x) \Delta B_{j/n} = n^{H-1} \sum_{q=1}^{(m+1)/2} a_{m+2,2q+1} S_k^{(2q+1)}(h_m(\phi(x, \cdot)))
\]

and, by (4.14),

\[
E \left| n^{(m+3)H-1} \sum_{j=0}^{k-1} h_m(X_{j/n}^x) (\Delta B_{j/n})^{m+2} - \mu_{m+3} n^{2H-1} \sum_{j=0}^{k-1} h_m(X_{j/n}^x) \Delta B_{j/n} \right|^2 = O(n^{(2H-1)\sqrt{(-4H)}}).
\]

Hence

\[
E \left| n^{(m+3)H-1} \sum_{k=0}^{n-1} \sigma h_m'(X_{i/k}^x) (\Delta B_{i/k})^{m+2} \sum_{j=0}^{k-1} h_m(X_{j/n}^x) (\Delta B_{j/n})^{m+2} - \mu_{m+3} n^{2H-1} \sum_{k=0}^{n-1} \sigma h_m'(X_{i/k}^x) \Delta B_{i/k} \right| = O(n^{\frac{1}{2}H-mH)\sqrt{(1-4H-mH)}}
\]
which tends to zero as $n \to \infty$, because $H > 2/(2m+3)$ implying $H > 1/(2m+2)$ and $H > 1/(m+4)$.

Moreover, by the mean value theorem:

$$\sum_{j=0}^{k-1} h_m(X_{ij/n}^x) \Delta B_{ij/n} = \int_0^{B_{ij/n}} h_m(\phi(x,z)) dz - \frac{1}{2} \sum_{j=0}^{k-1} \sigma h_m^2(X_{ij/n}^x) (\Delta B_{ij/n})^2,$$

for some $\theta_{ij/n}$ between $j/n$ and $(j+1)/n$. Consequently, since $H < 1/2$, we have

$$E \left| \sum_{j=0}^{k-1} h_m(X_{ij/n}^x) \Delta B_{ij/n} \right|^2 = O(n^{2-4H})$$

so that

$$E \left| n^{2H-1} \sum_{k=0}^{n-1} \sigma h_m^k(X_{ij/n}^x) (\Delta B_{ij/n})^{m+2} \frac{1}{2} \sum_{j=0}^{k-1} h_m(X_{ij/n}^x) \Delta B_{ij/n} \right| = O(n^{-(m+2)H}) \to 0.$$

Finally, by combining all these convergences to zero together, we get

$$n^{(m+3)H-1} \sum_{k=0}^{n-1} \sigma h_m^k(X_{ij/n}^x) (\Delta B_{ij/n})^{m+2} \sum_{j=0}^{k-1} h_m(X_{ij/n}^x) \Delta B_{ij/n} \to 0,$$

so that the proof of (4.3) is done in the case where $H > 2/(2m+3)$.

4. Proof of (4.3) for $H \in (1/(m+2), 2/(2m+3)]$. It suffices to use (4.13) with the appropriate $M$ for the considered $H$ and then to proceed as in the previous step. The remaining details are left to the reader.

5. Proof of (4.4). By going one step further in (4.11) using (4.9), we get

$$\hat{X}_1^{(n)}(x) = \phi(x,B_1) + \sum_{k=0}^{n-1} h_m(X_{ij/n}^x) (\Delta B_{ij/n})^{m+2} + \sum_{k=0}^{n-1} g_m(X_{ij/n}^x) (\Delta B_{ij/n})^{m+3}$$

$$+ O(n^2 \Delta_{n}^{2m+4}) + O(n^3 \Delta_{n}^{m+4}).$$

Whenever $m \geq 3$ and since $H = 1/2$, we have, as $n \to \infty$:

$$n^{(m+1)/2+1} \Delta_n^{m+4} \overset{\text{Prob}}{\to} 0 \quad \text{and} \quad n^{(m+1)/2+2} \Delta_n^{2m+4} \overset{\text{Prob}}{\to} 0.$$

Hence, for $m \geq 3$, (4.4) is an immediate consequence of (2.3) and of the previous two relations.

If $m = 1$, we rather need to use (4.13). Since $H = 1/2$, we have, as $n \to \infty$:

$$n^2 \Delta_n^5 \overset{\text{Prob}}{\to} 0, \quad n^3 \Delta_n^7 \overset{\text{Prob}}{\to} 0 \quad \text{and} \quad n^4 \Delta_n^9 \overset{\text{Prob}}{\to} 0.$$

Finally, combining these convergences with (2.1) (for $H = 1/2$), (2.3) and the fact that

$$E \left| n \sum_{k=0}^{n-1} \sigma h_1(X_{ij/n}^x) (\Delta B_{ij/n})^{m+2} \sum_{j=0}^{k-1} h_1(X_{ij/n}^x) (\Delta B_{ij/n})^{m+3} \right|^2$$

$$= n^2 \sum_{k=0}^{n-1} \sum_{j=0}^{k-1} E \left| \sigma h_1(X_{ij/n}^x) (\Delta B_{ij/n})^{m+2} \right|^2 = O(n^{-2}) \to 0 \quad \text{as} \quad n \to \infty,$$
we obtain (4.4) also for $m = 1$.

6. Proof of (4.5). By combining (4.10) with the fact that $X_t^x = \phi(x, B_t)$ and $\partial \phi / \partial y = \sigma \circ \phi$, we get

$$\hat{X}_1^{(n)} = X_1^x + \sigma(X_1^x) \sum_{k=0}^{n-1} h_m(X_{k/n}^x) (\Delta B_{k/n})^{m+2} + O(n \Delta_n^{m+3}) + O(n^2 \Delta_n^{2m+4}).$$

Since $H > 1/2$, we have, as $n \to \infty$,

$$n^{(m+1)H+1} \Delta_n^{m+3} \overset{\text{Prob}}{\to} 0 \quad \text{and} \quad n^{(m+1)H+2} \Delta_n^{2m+4} \overset{\text{Prob}}{\to} 0.$$

Hence (4.3) is an immediate consequence of (2.4).

Acknowledgement: We thank Jean Jacod for helpful discussion about stable convergence and especially about reference [6] and Serge Cohen for its suggestion of reference [7].
