Optimal convergence analysis for the eXtended Finite Element Method

Serge Nicaise 1, Yves Renard 2, Elie Chahine 3

Abstract
We establish some optimal a priori error estimate on some variants of the eXtended Finite Element Method (Xfem), namely the Xfem with a cut-off function and the standard Xfem with a fixed enrichment area. The results are established for the Lamé system (homogeneous isotropic elasticity) and the Laplace problem. The convergence of the numerical stress intensity factors is also investigated. We show some numerical experiments which corroborate the theoretical results.

Keywords: extended finite element method, error estimates, stress intensity factors.

1 Introduction
Inspired by the Pufem [26], the Xfem (extended finite element method) was introduced by Moës et al. in 1999 [28, 27] for plane linear isotropic elasticity problems (Lamé system) in cracked domains. The main advantage of this method is the ability to take into account the discontinuity across the crack and the asymptotic displacement at the crack tip by addition of special functions into the finite element space. It allows the use of a mesh which is independent of the geometry of the crack. This avoids the remeshing operations when the crack propagates and the corresponding re-interpolation operations which can cause numerical instabilities. In the original method, the asymptotic displacement is incorporated into the finite element space multiplied by the shape function of a background Lagrange finite element method. However, we deal also with a variant, introduced in [12], where the asymptotic displacement is multiplied by a cut-off function. This variant is similar to the classical singular enrichment method introduced in 1973 by Strang and Fix [32] but it additionally preserves the independence of the mesh to the geometry of the crack which is indeed the essential contribution of Xfem.

Another classical method to take into account a singular behavior of the solution is the dual singular function method introduced by M. Dobrowolski et al. in [5] (see also [19, 10]) or a more recent variant the singular complement method introduced by P. Ciarlet Jr. et al. in [17] (for a L-shape domain, see [29]). These methods require the use of dual singular functions which can be difficult to obtain in some situations (even for the Lamé system) or quite impossible to obtain when just the asymptotic behavior is known (for non-linear elasticity [2] or Mindlin plate model for instance).

The Xfem strategy can be adapted to various situations. See among many other references [3, 6, 7, 8, 23, 25, 36, 37, 35, 38]. In particular, a fictitious domain method can be

derived from the principle of Xfem (see [24, 4]) and it is possible to adapt some strategies when the asymptotic behavior is unknown or only partially known (see [11, 13, 14]).

In the present paper, we improve the results given in [12] concerning the variant which uses a cut-off function. We also give some additional error estimates concerning the stress intensity factors and the standard Xfem. The theoretical results are established for both the Lamé system and the Laplace problem. Some numerical tests that illustrate and confirm the theoretical results are presented.

2 The model problems

The analysis will be performed on a cracked domain $\Omega \subset \mathbb{R}^2$ for two model problems: The Laplace equation and the Lamé system. The crack $\Gamma_C$ is assumed to be straight. In both cases, the boundary $\partial \Omega$ of $\Omega$ is partitioned into $\Gamma_D$, $\Gamma_N$ and $\Gamma_C$ (see Fig. 1). A Dirichlet condition is prescribed on $\Gamma_D$, a Neumann one on $\Gamma_N$ while on the crack $\Gamma_C$ we consider an homogeneous Neumann condition.

![Figure 1: The cracked domain $\Omega$.](image)

The weak formulation of the (scalar) Laplace equation on this domain reads as follows:

$$
\begin{align*}
\text{Find } u \in V \text{ such that } & a(u, v) = l(v) \quad \forall v \in V, \\
a(u, v) &= \int_{\Omega} \nabla u \cdot \nabla v \, dx, \\
l(v) &= \int_{\Omega} fv \, dx + \int_{\Gamma_N} gv \, d\Gamma, \\
V &= \{v \in H^1(\Omega); \quad v = 0 \text{ on } \Gamma_D\}. 
\end{align*}
$$

(1)

While the one of the Lamé (vectorial) system (linear elasticity problem on this domain for an isotropic material) is:

$$
\begin{align*}
\text{Find } u \in V \text{ such that } & a(u, v) = l(v) \quad \forall v \in V, \\
a(u, v) &= \int_{\Omega} \sigma(u) : \varepsilon(v) \, dx, \\
l(v) &= \int_{\Omega} f \cdot v \, dx + \int_{\Gamma_N} g \cdot v \, d\Gamma, \\
\sigma(u) &= \lambda \text{tr}(\varepsilon(u)) I + 2\mu \varepsilon(u), \\
V &= \{v \in H^1(\Omega; \mathbb{R}^2); \quad v = 0 \text{ on } \Gamma_D\},
\end{align*}
$$

(2)

where $\sigma(u)$ denotes the stress tensor, $\varepsilon(u) = \frac{1}{2}(\nabla u + \nabla u^T)$ is the linearized strain tensor,
\( f \) and \( g \) are some external load densities on \( \Omega \) and \( \Gamma_N \) respectively, and \( \lambda > 0, \mu > 0 \) are the Lamé coefficients.

In both cases, we suppose \( \Omega, f \) and \( g \) smooth enough for the solution \( u \) of Problem (1) or (2) to be written as a sum of a singular part \( u_s \) and a regular part \( u - u_s \) (see [22, 21]) satisfying:

\[
    u - u_s \in H^2(\Omega; \mathbb{R}^d), \tag{3}
\]

with

\[
    d = 1 \quad \text{and} \quad u_s = K_L u_L, \tag{4}
\]

for the solution to the Laplace equation (1), and

\[
    d = 2 \quad \text{and} \quad u_s = K_I u_I + K_{II} u_{II}, \tag{5}
\]

for the solution to the Lamé system (2). The scalars \( K_L, K_I \) and \( K_{II} \) are the so-called stress intensity factors and the functions \( u_L, u_I \) and \( u_{II} \) are given in polar coordinates relatively to the crack tip (Fig. 2) by:

\[
    u_L(r, \theta) = \sqrt{r} \sin \frac{\theta}{2}, \tag{6}
\]

\[
    u_I(r, \theta) = \frac{1}{E} \sqrt{\frac{r}{2\pi}} (1 + \nu) \left( \cos \frac{\theta}{2} (\delta - \cos \theta) \right) \left( \sin \frac{\theta}{2} (\delta - \cos \theta) \right), \tag{7}
\]

\[
    u_{II}(r, \theta) = \frac{1}{E} \sqrt{\frac{r}{2\pi}} (1 + \nu) \left( \sin \frac{\theta}{2} (\delta + 2 + \cos \theta) \right) \left( \cos \frac{\theta}{2} (\delta - 2 + \cos \theta) \right), \tag{8}
\]

where \( \nu = \frac{\lambda}{\lambda + 2\mu} \) denotes the Poisson ratio, \( E = \frac{4\mu(\lambda + \mu)}{\lambda + 2\mu} \) the Young modulus and \( \delta = 3 - 4\nu \) (plane stress approximation). Note that \( u_L, u_I \) and \( u_{II} \) belong to \( H^{3/2-\eta}(\Omega) \) for any \( \eta > 0 \) (see [22]) which limits the order of the convergence rate of a classical finite element method to \( O(h^{1/2}) \) where \( h \) is the mesh parameter.

![Figure 2: Polar coordinates respectively to the crack tip \( \Omega \).](image)

### 3 Xfem with a cut-off function

The Xfem variant which uses a cut-off function was proposed in [12]. The principle of the standard Xfem (see [28, 27]) is to consider a mesh independent of the crack geometry. An Heaviside type function is used to represent the discontinuity across the straight crack:

\[
    H(x) = \begin{cases} 
    +1 & \text{if } (x - x^*) \cdot n \geq 0, \\
    -1 & \text{elsewhere},
    \end{cases} \tag{9}
\]
where $x^*$ denotes the crack tip and $n$ is a given normal to the crack. Moreover, the nonsmooth functions $u_L$, $u_I$ and $u_{II}$ are integrated to the discrete space to take into account the asymptotic behavior at the crack tip.

We consider an affine Lagrange finite element method defined on a regular triangulation $\mathcal{T}_h$ (in the sense of the Ciarlet [16]) of the non-cracked domain $\Omega$, $h$ being the mesh parameter i.e. the largest diameter of the elements of $\mathcal{T}_h$. The piecewise $P_1$ basis functions are denoted $\varphi_i$. In this section, we consider the variant of Xfem proposed in [12] for which a whole area around the crack tip is enriched by using a cut-off function denoted $\chi$. The approximation of the Laplace equation reads as

$$
\begin{align*}
\text{Find } & \ u^h \in V^h \text{ such that } a(u^h, v^h) = l(v^h) \quad \forall v^h \in V^h, \\
a(u^h, v^h) & = \int_{\Omega} \nabla u^h \cdot \nabla v^h \, dx, \\
l(v^h) & = \int_{\Omega} f v^h \, dx + \int_{\Gamma_N} g v^h \, d\Gamma,
\end{align*}
$$

$$V^h = \left\{ v^h = \sum_{i \in I} a_i \varphi_i + \sum_{i \in I_H} b_i H \varphi_i + K_{L,h} \chi u_L; \ a_i, b_i, K_{L,h} \in \mathbb{R} \right\}.
$$

(10)

where $I$ is the set of node indices of the $P_1$ finite element method, $I_H$ is the sub-set of node indices whose corresponding shape functions have their supports completely cut by the crack and $\chi$ is a $W^{2,\infty}(\Omega)$ cut-off function verifying for fixed $0 < r_0 < r_1$

$$
\begin{align*}
\chi(r) & = 1 \text{ if } r < r_0, \\
0 & < \chi(r) < 1 \text{ if } r_0 < r < r_1, \\
\chi(r) & = 0 \text{ if } r_1 < r.
\end{align*}
$$

(11)

Concerning now the Lamé system, we consider two different ways to incorporate the asymptotic displacement. The first one is directly based on a vectorial enrichment with $u_t$ and

![Figure 3: Enrichment strategy.](image)
where

\[ u(2), \] satisfies Condition (3). Then, the following estimate holds

\[ \| u - u^h \|_{1, \Omega} \lesssim h \| u - \chi u_s \|_{2, \Omega}, \] (15)

where \( u^h \) is the solution to Problem (10) (resp. Problem (12) or to Problem (13)), \( u_s \) is the singular part of \( u \) (see (5)) and \( \chi \) is the \( W^{2,\infty}(\Omega) \) cut-off function introduced before.

The outline of the proof globally follows the one of Theorem 1 in [12]. Some sub-optimal intermediary results are here replaced by optimal ones.

4 Optimal Error estimate for the Xfem with a cut-off function

We use the notation \( \alpha \lesssim \beta \) to signify that there exists a constant \( C > 0 \) independent of the mesh parameter and of the solution such that \( \alpha \leq C \beta \). For a non negative real number \( s \) let \( H^s(D) \) denote the standard Sobolev space of order \( s \) in \( D \) of norm (resp. semi-norm) denoted by \( \| \cdot \|_{s,D} \) (resp. \( | \cdot |_{s,D} \)), see for instance [1].

The aim of this section is to establish the following result which is the optimal version of Theorem 1 in [12]:

**Theorem 1** Assume that the displacement field \( u \), solution to Problem (1) (resp. Problem (2)), satisfies Condition (3). Then, the following estimate holds

\[ \| u - u^h \|_{1, \Omega} \lesssim h \| u - \chi u_s \|_{2, \Omega}, \] (15)

where \( u^h \) is the solution to Problem (10) (resp. to Problem (12) or to Problem (13)), \( u_s \) is the singular part of \( u \) (see (5)) and \( \chi \) is the \( W^{2,\infty}(\Omega) \) cut-off function introduced before.

The outline of the proof globally follows the one of Theorem 1 in [12]. Some sub-optimal intermediary results are here replaced by optimal ones.
We recall the definition of the adapted interpolation operator $\Pi^h$. The interpolation error estimates are then computed locally over every different type of triangles: triangles totally enriched by the Heaviside function, triangles partially enriched by the Heaviside function and the triangle containing the crack-tip.

The domain $\Omega$ is divided into $\Omega_1$ and $\Omega_2$ according to the crack and a straight extension of the crack (Fig.4) such that the value of $H$ is $(-1)^k$ on $\Omega_k$, $k = 1, 2$. Let us denote $u_r = u - \chi u_s$, and $u^k_r$ the restriction of $u_r$ to $\Omega_k$, $k \in \{1, 2\}$. Then, there exists in $H^2(\Omega; \mathbb{R}^d)$ an extension $\tilde{u}^k_r$ of $u^k_r$ on $\Omega$ such that (see [1])

$$\|\tilde{u}^1_r\|_{2,\Omega_1} \lesssim \|u^1_r\|_{2,\Omega_1}, \quad (16)$$

$$\|\tilde{u}^2_r\|_{2,\Omega_2} \lesssim \|u^2_r\|_{2,\Omega_2}. \quad (17)$$

Definition 1 (from [12]) Given a displacement field $u$ satisfying (3) and two extensions $\tilde{u}^1_r$ and $\tilde{u}^2_r$ respectively of $u^1$ and $u^2$ in $H^2(\Omega; \mathbb{R}^d)$, we define $\Pi^h u$ as the element of $V^h$ such that

$$\Pi^h u = \sum_{i \in I} a_i \varphi_i + \sum_{i \in I_H} b_i H \varphi_i + \chi u_s,$$  

(18)

where $a_i, b_i$ are given as follows ($x_i$ denotes the node associated to $\varphi_i$):

- if $i \in \{I \setminus I_H\}$ then $a_i = u_r(x_i)$,
- if $i \in I_H$ and $x_i \in \partial \Omega_k$ then $(k \in \{1, 2\}, l \neq k) \left\{ \begin{array}{ll}
    a_i = \frac{1}{2} \left( u^k_r(x_i) + \tilde{u}^l_r(x_i) \right), \\
    b_i = \frac{1}{2} \left( u^k_r(x_i) - \tilde{u}^l_r(x_i) \right) (-1)^k.
  \end{array} \right.$ (19)

From this definition, the following result holds:

Lemma 1 (from [12]) The function $\Pi^h u$ satisfies

(i) $\Pi^h u = I^h u_r + \chi u_s$ over a triangle non-enriched by $H$,
(ii) $\Pi^h u|_{K \cap \Omega_k} = I^h \tilde{u}^k_r + \chi u_s$ over a triangle $K$ totally enriched by $H$,

where $I^h$ denotes the classical interpolation operator for the associated finite element method.
For $K$ a subset of $\Omega$, we denote $h_K = \text{diam}(K) = \max_{x_1, x_2 \in K} |x_1 - x_2|$ and $\rho_K = \{\text{sup}(\text{diam}(B)) : B \text{ ball of } \mathbb{R}^2, B \subset K\}$. The following lemma, established in [12], derives simply from the classical interpolation of the extensions of $u^1_r$ and $u^2_r$.

**Lemma 2** (from [12]) Let $\mathcal{T}_h^H$ be the set of triangles totally enriched by $H$ (Fig.3) and $\sigma_K = h_K \rho_K^1$. For all $K$ in $\mathcal{T}_h^H$, and for all $u$ satisfying (3) we have the estimates

\[
\|u - \Pi_h u\|_{1, K \cap \partial \Omega} \lesssim h_K \sigma_K \|\tilde{u}^1_r\|_{2, K},
\]

and

\[
\|u - \Pi_h u\|_{1, K \cap \partial \Omega} \lesssim h_K \sigma_K \|\tilde{u}^2_r\|_{2, K}.
\]

The optimal convergence is of course obtained for non enriched triangles. It remains to treat the partially enriched triangles and the triangle containing the crack tip. We will now detailed the optimal intermediary results which are original in this paper.

Let us start with the Laplace equation and recall that in that case $u^1_r$ and $u^2_r$ satisfy

\[
\partial_n u^1_r = \partial_n u^2_r = 0 \text{ on } \Gamma_C.
\]

Since the extension $\tilde{u}^1_r$ and $\tilde{u}^2_r$ are $H^2(\Omega)$ extension, they also satisfy the Neumann boundary condition on $\Gamma_C$, namely

\[
\partial_n \tilde{u}^1_r = \partial_n \tilde{u}^2_r = 0 \text{ on } \Gamma_C.
\]

We now give the main technical result.

**Lemma 3** Assume that $x_1 \in \Omega_1$ is a node belonging to a triangle $K$ containing the crack tip. Then

\[
|u^1_r(x_1) - \tilde{u}^2_r(x_1)| \lesssim h_K |\tilde{u}^1_r - \tilde{u}^2_r|_{L^2(B(0, h_K)}.
\]

**Proof:** For shortness write $v = \tilde{u}^1_r - \tilde{u}^2_r$. Using a Taylor expansion, we have

\[
v(x_1) = \int_0^1 (x_1^{(1)} \partial_1 v(tx_1) + x_1^{(2)} \partial_2 v(tx_1)) dt,
\]

where $x_1 = (x_1^{(1)}, x_1^{(2)})$. Without loss of generality and modulo an orthonormal change of coordinates we assume that the position of the crack tip is $(0, 0)$ and the crack $\Gamma_C$ is a part of $(\mathbb{R}_-, 0)$. By setting $v^{(1)} = \partial_1 v$ and $v^{(2)} = \partial_2 v$, and making the change of variable $s = tx_1$, the above identity is equivalent to

\[
v(x_1) = \int_e (n_2 v^{(1)}(s) - n_1 v^{(2)}(s)) ds,
\]

where $e$ is the edge joining the crack tip and $x_1$ and $n = (n_1, n_2)$ is (one of) the normal vector to $e$. Denote by $C$ the truncated sector determined by $e$ and the crack:

\[
C = \{(r \cos \theta, r \sin \theta) : 0 < r < h_1, \theta_0 < \theta < \pi\},
\]

when $x_1 = (h_1 \cos \theta_0, h_1 \sin \theta_0)$, see Fig. 6. Now setting $e_2 = \{(h_1 \cos \theta, h_1 \sin \theta) : \theta_0 < \theta < \pi\}$, by Green’s formula we remark that

\[
\int_C \partial_1 v^{(2)} dx = \int_{\partial C} n_1 v^{(2)} ds = \int_e n_1 v^{(2)} ds + \int_{e_2} n_1 v^{(2)} ds,
\]

because $n_1 = 0$ on $\Gamma_C$. Hence

\[
\int_e n_1 v^{(2)} ds = \int_C \partial_1 v^{(2)} dx - \int_{e_2} n_1 v^{(2)} ds.
\]
The first term of this right-hand side will be estimated by a simple Cauchy-Schwarz inequality. For the second term by a scaling argument, we show that

\[ \int_{e_2} |v^{(2)}| \, ds \lesssim h_1 \| \nabla v^{(2)} \|_{B(0,h_1)}. \]  

(27)

\[ \begin{align*}
\Omega_1 & \quad \Omega_2 \\
\Gamma_C & \quad \theta = -\pi & \tilde{\Gamma}_C & \quad \theta = \pi \\
x_1 & \quad e_2 & \quad C & \quad D
\end{align*} \]

Figure 6: The truncated sector C.

Indeed by construction \( v^{(2)} \) satisfies

\[ v^{(2)} = 0 \text{ on } \Gamma_C. \]

Therefore the change of variable \( x = h_1 \hat{x} \) maps \( B(0,h_1) \) to the unit ball. By setting \( \hat{\phi}^{(2)}(\hat{x}) = v^{(2)}(x) \), we deduce that

\[ \int_{e_2} |v^{(2)}| \, ds \leq \int_{\partial B(0,h_1)} |\hat{\phi}^{(2)}| \, d\hat{s} \]

\[ = h_1 \int_{\partial B(0,1)} |\hat{\phi}^{(2)}| \, d\hat{s} \]

\[ \lesssim h_1 \left( \int_{B(0,1)} |\nabla \hat{\phi}^{(2)}|^2 \, d\hat{x} \right)^{\frac{1}{2}}. \]

This last estimate follows from the property

\[ \hat{\phi}^{(2)}(\hat{x}) = 0 \text{ on } \{(x_1,0) : -1 < x_1 < 0\}, \]

and the compact embedding of \( H^1(B(0,1)) \) into \( L^2(B(0,1)) \). Coming back to \( B(0,h_1) \), we obtain (27).

Using the estimate (27) into (26) and Cauchy-Schwarz inequality, we have shown that

\[ |\int_{e_1} n_1 v^{(2)} \, ds| \lesssim h_1 \| \nabla v^{(2)} \|_{B(0,h_1)}. \]  

(28)

Let us now pass to the estimate of \( \int_{e} n_2 v^{(1)}(s) \, ds \): Denote by \( D \) the truncated sector determined by \( e \) and the extended crack:

\[ D = \{(r \cos \theta, r \sin \theta) : 0 < r < h_1 \quad 0 < \theta < \theta_0\}, \]

when we recall that \( x_1 = (h_1 \cos \theta_0, h_1 \sin \theta_0) \) (see Fig. 6). As before setting \( e_3 = \{(h_1 \cos \theta, h_1 \sin \theta) : 0 < \theta < \theta_0\} \), we remark that

\[ \int_D \partial_2 v^{(1)} \, dx = \int_{\partial D} n_2 v^{(1)} \, ds = \int_{e} n_2 v^{(1)} \, ds + \int_{e_3} n_2 v^{(1)} \, ds, \]
because \( v^{(1)} = 0 \) on \( \tilde{\Gamma}_C = \{(x_1,0) : x_1 > 0\} \), the extension of the crack \( \Gamma_C \) to \( x_1 > 0 \). Hence

\[
\int_{e} n_2 v^{(1)} \, ds = \int_D \partial_2 v^{(1)} \, dx - \int_{e_3} n_2 v^{(1)} \, ds.
\]

(29)

It suffices to estimate the second term of this right-hand side. Again using a scaling argument, we show that

\[
\int_{e_3} |v^{(1)}| \, ds \lesssim h_1 \| \nabla v^{(1)} \|_{B(0,h_1)}.
\]

(30)

Indeed by construction \( v^{(1)} \) satisfies

\[
v^{(1)} = 0 \text{ on } \tilde{\Gamma}_C.
\]

Therefore the same scaling arguments as before lead to (30).

Using the estimate (30) into (29) and Cauchy-Schwarz inequality, we have shown that

\[
|\int_{e} n_2 v^{(1)} \, ds| \lesssim h_1 \| \nabla v^{(1)} \|_{B(0,h_1)}.
\]

(31)

The estimates (28) and (31) into the identity (25) lead to the estimate (24) because \( h_1 \leq h_K \).

\[\Box\]

Let us go on with the Lamé system and recall that in that case \( u_1^r \) and \( u_2^r \) satisfy

\[
\sigma(u_1^r) \cdot n = \sigma(u_2^r) \cdot n = 0 \text{ on } \Gamma_C.
\]

(32)

Since the extension \( \tilde{u}_1^r \) and \( \tilde{u}_2^r \) belong to \( H^2(\tilde{\Omega}; \mathbb{R}^2) \), they also satisfy the traction free boundary condition on \( \Gamma_C \), namely

\[
\sigma(\tilde{u}_1^r) \cdot n = \sigma(\tilde{u}_2^r) \cdot n = 0 \text{ on } \Gamma_C.
\]

(33)

Lemma 4 Assume that \( x_1 \in \Omega_1 \) is a node belonging to a triangle \( K \) containing the crack tip. Then the estimate (24) holds.

Proof: The proof starts as before with the identity (25).

We notice that by (33) and since \( n = (0,1)^\top \) on \( \Gamma_C \), \( v = \tilde{u}_1^r - \tilde{u}_2^r \) satisfies

\[
\lambda(\partial_1 v_1 + \partial_2 v_2) + \mu(\partial_1 v_2 + \partial_2 v_1) = 0 \text{ on } \Gamma_C,
\]

(34)

\[
(\lambda + 2\mu)\partial_2 v_2 + \lambda \partial_1 v_1 = 0 \text{ on } \Gamma_C,
\]

(35)

where \( v_1, v_2 \) are the two components of \( v \), i.e., \( v = (v_1, v_2)^\top \). Note that by construction, we also have \( v = 0 \) on \( \tilde{\Gamma}_C \) and therefore

\[
\partial_1 v_1 = \partial_1 v_2 = 0 \text{ on } \tilde{\Gamma}_C.
\]

(36)

Since \( v^{(1)} \) still satisfies

\[
v^{(1)} = 0 \text{ on } \tilde{\Gamma}_C,
\]

the arguments of the previous lemma show that (31) is valid.

For the estimate of the term involving \( v^{(1)} \), since \( n_1 = 0 \) on \( \Gamma_C \), as before the identity (26) holds. To estimate the second term of the right-hand side of (26), we again use a scaling argument: The change of variable \( x = h_1 \hat{x} \) maps \( B(0,h_1) \) to the unit ball and by setting \( \hat{w}(\hat{x}) = \nabla v(x) \), where

\[
\nabla v = \begin{pmatrix} \partial_1 v_1 & \partial_2 v_1 \\ \partial_1 v_2 & \partial_2 v_2 \end{pmatrix},
\]
we deduce that
\[ \int_{\Omega} |v^{(2)}| \, ds \leq \int_{\partial B(0,h_1)} |v^{(2)}| \, ds \]
\[ \leq \int_{\partial B(0,h_1)} |\nabla v| \, ds \]
\[ \leq h_1 \int_{\partial B(0,1)} |\tilde{w}| \, ds. \]

Now we notice that the conditions (34), (35) and (36) satisfied by \( v \) lead to
\[ \lambda(\tilde{w}_{11} + \tilde{w}_{22}) + \mu(\tilde{w}_{21} + \tilde{w}_{12}) = 0 \text{ on } \{(x_1,0) : -1 < x_1 < 0\}, \quad (37) \]
\[ (\lambda + 2\mu)\tilde{w}_{22} + \lambda\tilde{w}_{11} = 0 \text{ on } \{(x_1,0) : -1 < x_1 < 0\}, \quad (38) \]
\[ \tilde{w}_{11} = \tilde{w}_{12} = 0 \text{ on } \{(x_1,0) : 0 < x_1 < 1\}. \quad (39) \]

Hence the compact embedding of \( H^1(B(0,1)) \) into \( L^2(B(0,1)) \) and a contradiction argument lead to
\[ \int_{\partial B(0,1)} |\tilde{w}| \, ds \lesssim \|w\|_{1,B(0,1)} \lesssim |w|_{1,B(0,1)}. \]

This last estimate holds since otherwise we would find a vector field \( v \in H^1(B(0,1))^{2\times 2} \) satisfying (37) to (39) such that
\[ |w|_{1,B(0,1)} = 0 \text{ and } \|w\|_{0,B(0,1)} = 1. \]

Such a matrix field does not exist because \( w \) would be a constant matrix and by (37) to (39), it would be zero.

This estimate leads to (27) and we conclude as in the previous Lemma. \( \Box \)

These lemmas allow to treat the non-optimal cases from [12] as follows:

**Corollary 1** Let \( K \) be a triangle partially enriched and let \( K^* = K \setminus \Gamma_C \). Then
\[ ||u - \Pi^h u||_{1,K^*} \lesssim h_K (|\tilde{u}_r^{1,1,2,B(0,2h_K)}| + |\tilde{u}_r^{2,1,2,B(0,2h_K)}|). \]

**Proof:** It is sufficient to estimate \( ||u_r - \Pi^h u_r||_{1,K^*} \) since the singular part of \( u - \Pi^h u \) vanishes. We treat the situation of Fig. 5 (b). Other situations can be treated similarly.

We have
\[ \Pi^h u_r = u_r^1(x_1)\varphi_1 + u_r^2(x_2)\varphi_2 + \tilde{u}_r^2(x_3)\varphi_3 \text{ on } K_2 = K \cap \Omega_2, \]

or equivalently
\[ \Pi^h u_r = \tilde{u}_r^2(x_1)\varphi_1 + u_r^2(x_2)\varphi_2 + \tilde{u}_r^2(x_3)\varphi_3 + (u_r^1(x_1) - \tilde{u}_r^2(x_1))\varphi_1 \text{ on } K_2 \]
\[ = \Pi^h \tilde{u}_r^2 + (u_r^1(x_1) - \tilde{u}_r^2(x_1))\varphi_1 \text{ on } K_2. \]

By the triangular inequality, we may write
\[ ||u_r - \Pi^h u_r||_{1,K_2} \leq ||u_r^1 - \Pi^h \tilde{u}_r^2||_{1,K_2} + ||u_r^1(x_1) - \tilde{u}_r^2(x_1)||_1 \varphi_1||_{1,K_2} \]
\[ \lesssim ||\tilde{u}_r^2 - \Pi^h \tilde{u}_r^2||_{1,K} + ||u_r^1(x_1) - \tilde{u}_r^2(x_1)||. \]

By a standard interpolation error estimate and Lemma 3 (or 4), we conclude that
\[ ||u_r - \Pi^h u_r||_{1,K_2} \lesssim h_K (|\tilde{u}_r^{1,2,B(0,2h_K)}| + |\tilde{u}_r^{2,1,2,B(0,2h_K)}|). \]
For the part on $K_1 = K \cap \Omega_1$, we remark that
\[
\Pi^h u_r = u_r^1(x_1) \varphi_1 + u_r^2(x_2) \varphi_2 + u_r^3(x_3) \varphi_3 \quad \text{on} \ K_1
\]
\[
= \Pi^h \tilde{u}_r^1 + (\tilde{u}_r^1(x_1) - u_r^2(x_1)) \varphi_2 \quad \text{on} \ K_2.
\]
And we conclude as before because $\tilde{u}_r^1 - u_r^2$ satisfies the same conditions than $u_r^1 - \tilde{u}_r^2$ on $\Gamma_C$ and $\bar{\Gamma}_C$. \hfill \Box

**Corollary 2** Let $K$ be the triangle containing the crack tip. Then
\[
\|u - \Pi^h u\|_{1,K} \lesssim h_K (|\tilde{u}_r^1|_{2,B(0,h_K)} + |\tilde{u}_r^2|_{2,B(0,h_K)}).
\] 

**Proof:** In this case we have
\[
\Pi^h u_r = u_r^1(x_1) \varphi_1 + u_r^2(x_2) \varphi_2 + u_r^3(x_3) \varphi_3 \quad \text{on} \ K.
\]
Without loss of generality, we may assume that $K$ has one vertex $x_1$ in $\Omega_1$ and the two other ones $x_2, x_3$ in $\Omega_2$. In this case on $K_1 = K \cap \Omega_1$, we have
\[
\|u_r - \Pi^h u_r\|_{1,K_1} \leq \|u_r^1 - \Pi^h \tilde{u}_r^1\|_{1,K_1} + |u_r^1(x_2) - \tilde{u}_r^1(x_2)||\varphi_2||_{1,K_1} + |u_r^3(x_3) - \tilde{u}_r^3(x_3)||\varphi_3||_{1,K_1}
\]
\[
\lesssim |\tilde{u}_r^1 - \Pi^h \tilde{u}_r^1|_{1,K} + |u_r^1(x_2) - \tilde{u}_r^1(x_2)|| + |u_r^3(x_3) - \tilde{u}_r^3(x_3)|.
\]
We then conclude as in the previous Corollary. The estimate on $K_2 = K \cap \Omega_2$ is treated similarly. \hfill \Box

As in [12], these two Corollaries and Lemma 2 lead to the global error estimate of Theorem 1. This analysis is corroborated by the numerical tests also presented in [12]. We reproduce on Fig. 8 the convergence curves obtained in this paper for the approximation (13).

These numerical tests were done on a non-cracked domain defined by $\Omega = [-0.5; 0.5] \times [-0.5; 0.5]$ and the crack was the line segment $\Gamma_C = [-0.5; 0] \times \{0\}$. The cut-off function $\chi \in C^2(\Omega)$ was defined such that
\[
\chi(r) = \begin{cases} 
1 & \text{if } r < r_0 = 0.01, \\
0 & \text{if } r > r_1 = 0.49,
\end{cases}
\] 

and $\chi$ was identical to a fifth degree polynomial for $r_0 \leq r \leq r_1$. 

11
The reference solution, a mixed mode (from [12]).

The exact solution was a combination of a regular solution to the elasticity problem, the mode I and the mode II analytical solutions and a higher order mode (for the deformed configuration, see Fig. 7 with the Von Mises stress). Fig. 8 shows a comparisons of the convergence curves of the non-enriched classical method, the standard Xfem and the cut-off strategy. The optimal rate is obtained for both the cut-off enrichment and the standard Xfem with a fixed enrichment area.

Figure 8: $H^1$ error with respect to the number of cells in each direction ($ns$) for a mixed mode and different enrichment strategies of a P1 elements (from [12]).

Fig. 9 and 10 present some new numerical tests on the comparison between strategies.
(12) and (13) (i.e. between a scalar and a vectorial enrichment) for the same experimental situation. The discrete space corresponding to the scalar enrichment (13) strictly includes the one for the vectorial enrichment (12). However, the gain in $H^1(\Omega)$ norm for the error is rather small (Fig. 9). Consequently, the vectorial enrichment appears to be a better choice since the number of additional degrees of freedom is lower and the condition number of the linear system obtained is better (Fig. 10).

![Figure 9: $H^1$ error with respect to the number of cells in each direction (ns). Comparison of strategies (12) and (13).](image1)

![Figure 10: Condition number of the linear system. Comparison of strategies (12) and (13).](image2)
5 Error estimate on the stress intensity factor

In this section, we show an error estimate between the exact stress intensity factors and the approximated ones. Let us start with the Laplace equation. Recall that we write

$$u = u_r + K_L \chi u_L,$$

and that our Galerkin solution \( u_h \in V_h \) solution to (12) admits the splitting

$$u_h = u_r + K_{L,h} \chi u_L,$$

where \( u_r \in S^h \), the space \( S^h \) being defined by

$$S^h = \left\{ v^h = \sum_{i \in I} a_i \varphi_i + \sum_{i \in H} b_i H \varphi_i; \ a_i, b_i \in \mathbb{R} \right\},$$

so that our approximation space \( V_h \) is spanned by \( S^h \) plus the singular function \( \chi u_L \).

Adapting the arguments from Theorem 9.1 of [9] we have the next error estimate:

**Theorem 2** Assume that the triangulation is quasi-uniform in the sense that

$$h \lesssim h_K \ \forall K \in \mathcal{T}_h.$$

Then we have

$$|K_L - K_{L,h}| \lesssim h^{\frac{1}{2}}.$$ (43)

**Proof:** As in Theorem 9.1 of [9], we have

$$K_L - K_{L,h} = - \frac{a((I - G_h)u_r, (I - G_h)(\chi u_L))}{a((I - G_h)(\chi u_L), (I - G_h)(\chi u_L))},$$

where \( G_h u \) is the Galerkin approximation of \( u \) on \( S^h \), namely \( G_h u \in S^h \) is the unique solution of

$$a(G_h u, v_h) = a(u, v_h) \ \forall v_h \in S^h.$$

By Cauchy-Schwarz’s inequality, we deduce that

$$|K_L - K_{L,h}| \leq \frac{\|(I - G_h)u_r\|_{1,\Omega}}{\|(I - G_h)(\chi u_L)\|_{1,\Omega}},$$ (44)

Since \( u_r \) belongs to \( H^2(\Omega) \) by Theorem 1, we have

$$\|(I - G_h)u_r\|_{1,\Omega} \lesssim h|u_r|_{2,\Omega},$$ (45)

and it remains to estimate from below the denominator of (44). For that purpose, we need to adapt the arguments from Lemma 7.1 of [9] because here the triangulation is not aligned with the crack. The main point is to find a small truncated cone \( C_\rho \) included into the triangle \( K \) containing the crack tip with \( \rho \) equivalent to \( h \). Let us denote by \( x_i, i = 1, 2, 3 \) the three nodes of \( K \). First we remark that by a scaling argument we have

$$\max_{i=1,2,3} |x_i| \geq \frac{\rho K}{\sqrt{2}} \max_{i=1,2,3} |\hat{x}_i - \hat{O}|,$$

where \( |x_i| \) is the Euclidean norm of \( x_i \), \( \hat{O} \) is the pull back of the crack tip \( O \) by the affine transformation \( F_K \) that sends the standard reference element \( \hat{K} \) to \( K \). Simple calculations show that

$$\max_{i=1,2,3} |\hat{x}_i - \hat{O}| \geq \frac{1}{4},$$
and therefore since the triangulation is regular we have
\[
\max_{i=1,2,3} |x_i| \gtrsim h_K.
\]

We now fix \(j \in \{1, 2, 3\}\) such that
\[
|x_j| = \max_{i=1,2,3} |x_i| \gtrsim h_K.
\]

Let \(e_1\) and \(e_2\) be the two edges of \(K\) having \(x_j\) as vertex and denote by \(\gamma_\ell, \ell = 1, 2\), the angle between \(e_\ell\) and the segment joining \(x_j\) to \(O\). Without loss of generality we may assume that \(\gamma_1 \geq \gamma_2\), and therefore
\[
\gamma_1 \geq \frac{\alpha_0}{2},
\]
where \(\alpha_0 \in (0, \pi/3)\) is the minimal angle of all triangles of \(\mathcal{K}_h\) (equivalent to the regularity of the mesh thanks to Zlamal’s result [39]).

![Figure 11: Sub-triangle \(K_1\).](image)

We now consider the sub-triangle \(K_1\) of \(K\) of vertices \(O, x_j, m\), where \(m\) is the mid-point of the edge \(e_1\). Denote that \(\alpha\) and \(\beta\) the angle of \(K_1\) at \(O\) and \(m\) respectively (see Fig. 11). Now if \(2l\) is the length of the edge \(e_1\), by the sinus formula, we notice that
\[
\frac{\sin \alpha}{\sin \beta} = \frac{l}{|x_j|} \sim 1.
\]
This property and the fact that
\[
2\alpha_0 \leq \alpha + \beta = \pi - \gamma_1 \leq \pi - \frac{\alpha_0}{2},
\]
leads to the existence of a minimal angle \(\alpha_1 > 0\) (independent of \(h\)) such that
\[
\alpha > \alpha_1.
\]

Denoting by \(\rho\) the distance from \(O\) to \(m\), again by the sinus formula, we have
\[
\rho = \frac{\sin \gamma_1}{\sin \alpha} l \sim h_K,
\]
due to the previous property and the fact that \(\alpha \leq \alpha + \beta \leq \pi - \frac{\alpha_0}{2}\).

We now denote by \(\theta_O\) the angle of the half-line containing the segment joining \(O\) to \(x_j\) and consider the truncated cone:
\[
C_\rho = \{(r \cos \theta, r \sin \theta) : 0 < r < \rho, \theta_O < \theta < \theta_O + \alpha_1\}.
\]
By construction, $C_\rho$ is included into $K$, and degenerates only in the radial direction. Indeed, by setting $C = \{(s \cos \theta, s \sin \theta) : 0 < s < 1 \ 0 < \theta < \alpha_1\}$ we can introduce the change of variables

$$F : C \to C_\rho : (s, \omega) \to (\rho s, \theta_O + \omega).$$

Then for every $w_h \in V^h$ we see that

$$\|\chi u - w_h\|_{1, \Omega} \geq \|u - w_h\|_{1, C_\rho} \gtrsim |u \circ F - w_h \circ F|_{1, C}.$$  

Since $w_h \circ F$ belongs to $P_1(C)$, we deduce that

$$\|\chi u - w_h\|_{1, \Omega} \gtrsim |(I - P)(u \circ F)|_{1, C},$$

where $P$ is the projection on $P_1(C)$ with respect to the inner product of $H^1(C)/P_0(C)$.

Since $u_L(r, \theta) = r^{1/2} \sin \frac{\theta}{2}$, we have

$$u_L \circ F(s, \omega) = \rho^{1/2} s^{1/2} \sin(\frac{\theta_O + \omega}{2}) = \rho^{1/2} (\sin \frac{\theta_O}{2} S_D(s, \omega) + \cos \frac{\theta_O}{2} S_N(s, \omega)),$$

where we have set

$$S_N(s, \omega) = s^{1/2} \sin \frac{\omega}{2} \text{ and } S_D(s, \omega) = s^{1/2} \cos \frac{\omega}{2}.$$

With these notations, we have

$$(I - P)(u_L \circ F) = \rho^{1/2} (\sin \frac{\theta_O}{2}(I - P)S_D + \cos \frac{\theta_O}{2}(I - P)S_N),$$

and therefore

$$\|\chi u - w_h\|_{1, \Omega} \gtrsim \rho^{1/2} |(I - P)S_D + \cos \frac{\theta_O}{2}(I - P)S_N|_{1, C}.$$  

If we can show that

$$|\sin \frac{\theta_O}{2}(I - P)S_D + \cos \frac{\theta_O}{2}(I - P)S_N|_{1, C} \gtrsim 1,$$  \hspace{1cm} (46)

then

$$\|\chi u - w_h\|_{1, \Omega} \gtrsim \rho^{1/2} \gtrsim h^{1/2}.  \hspace{1cm} (47)$$

This estimate with (45) in (44) then lead to the conclusion.

It remains to prove (46). For that purpose, we introduce the function $g$ from $[-\frac{\pi}{2}, \frac{\pi}{2}]$ into $\mathbb{R}$ defined by

$$g(\gamma) = |\sin \gamma(I - P)S_D + \cos \gamma(I - P)S_N|_{1, C}.$$  

We first notice that $g(\gamma) > 0$ for all $\gamma \in [-\frac{\pi}{2}, \frac{\pi}{2}]$ simply because $\sin \gamma S_D + \cos \gamma S_N$ is not a polynomial. Moreover, $g$ is clearly continuous. Therefore

$$\min_{\gamma \in [-\frac{\pi}{2}, \frac{\pi}{2}]} g(\gamma) = g(\gamma_0) > 0,$$

for some $\gamma_0 \in [-\frac{\pi}{2}, \frac{\pi}{2}]$. The main point is that this minimum is now independent of $\theta_O$ and therefore the estimate (46) is proved, and the Theorem follows. \qed
In the same manner for the Lamé system approximated by (12) we recall that

\[ u = u_r + K_I \chi u_I + K_{II} \chi u_{II} , \]

and that our Galerkin solution \( u_h \in V_h \) admits the splitting

\[ u_h = u_{rh} + K_{I,h} \chi u_I + K_{II,h} \chi u_{II} \]

where \( u_{rh} \in (S^h)^2 \).

As before, we can prove the

**Theorem 3** Assume that the triangulation is quasi-uniform in the sense that

\[ h \lesssim h_K \quad \forall K \in \mathcal{T}_h. \]

Then we have

\[ |K_I - K_{I,h}| + |K_{II} - K_{II,h}| \lesssim h^{\frac{1}{2}}. \]  

(48)

**Proof:** Following [9], we introduce

\[ V_I^h = (S^h)^2 \oplus \text{Span} \{ \chi u_I \} \text{ and } V_{II}^h = (S^h)^2 \oplus \text{Span} \{ \chi u_{II} \}, \]

and denote by \( G_{I,h} u \) and \( G_{II,h} u \) the Galerkin approximation of \( u \) on \( V_I^h \) and \( V_{II}^h \) respectively. By Theorem 9.1 of [9] we know that

\[ K_I - K_{I,h} = -\frac{a((I - G_{I,h})u_r, (I - G_{I,h})(\chi u_I))}{a((I - G_{I,h})(\chi u_I), (I - G_{I,h})(\chi u_I))}, \]

\[ K_{II} - K_{II,h} = -\frac{a((I - G_{II,h})u_r, (I - G_{II,h})(\chi u_{II}))}{a((I - G_{II,h})(\chi u_{II}), (I - G_{II,h})(\chi u_{II}))}. \]

Therefore by Cauchy-Schwarz’s and Korn’s inequalities, we have

\[ |K_I - K_{I,h}| \lesssim \frac{\|(I - G_{I,h})u_r\|_{1,\Omega}}{\|(I - G_{I,h})(\chi u_I)\|_{1,\Omega}}, \]

\[ |K_{II} - K_{II,h}| \lesssim \frac{\|(I - G_{II,h})u_r\|_{1,\Omega}}{\|(I - G_{II,h})(\chi u_{II})\|_{1,\Omega}}. \]

The remainder of the proof is the same as the one of the previous Theorem. □
Let us now present some numerical experiments obtained on the Lamé system with the same reference solution as the one on Fig. 7. The implementation of the discrete problem (12) uses Getfem++, the freely available C++ finite element library developed by our team (see [30]). The two stress intensity factors have the same value. The approximation of the stress intensity factor given by $K_{I,h}$ and $K_{II,h}$ in (12) is presented on Fig. 12. Different values of the radiuses $r_0$ and $r_1$ corresponding to the definition of the cut-off function (11) are tested in order to show the crucial influence of the shape of the cut-off function. The optimal rate of convergence is reached in the two cases $(r_0, r_1) = (0.01, 0.4)$ and $(r_0, r_1) = (0.01, 0.2)$. The sharper is the cut-off function, the worst is the approximation of the stress intensity factors. In the case $(r_0, r_1) = (0.2, 0.4)$, the optimal rate of convergence is not reached in the range of values of $h$ studied.

This convergence rate is lower than the one obtained by J-integral and interaction integral (see [18, 28] for the principle and [33, 34, 25] for some numerical tests). Such methods require a postprocessing but are superconvergent, for instance in [25] the order of convergence numerically observed for a $P_1$ finite element method is close to $O(h^2)$. However, the advantage of the coefficients $K_{I,h}$ and $K_{II,h}$ of (12) is that they are directly given by the approximation without any postprocessing. Moreover, there is no particular difficulty when the crack tip is near a boundary of the domain.

6 Optimal error estimate for the standard Xfem

We give now an a priori error estimate for the standard Xfem with a fixed enrichment area. In the original method proposed in [28] the enrichment with the asymptotic displacement at
the crack tip is done only on the element containing the crack tip. The rate of convergence of this method is the same than the one without the enrichment \(i.e. O(\sqrt{h})\), see \([31, 25]\) since the area of enrichment tends to vanish when the mesh parameter decreases. Of course, this rate of convergence is not difficult to establish. Instead, we prove here an optimal error estimate for the strategy introduced independently in \([25]\) and \([3]\) and called “Xfem with a fixed enrichment area” in the first reference and “Xfem with geometrical enrichment” in the second one and consisting in an enrichment area for the asymptotic displacement whose size is independent of the mesh parameter. The approximation of the Laplace equation with this method reads as

\[
\begin{aligned}
\text{Find } u^h \in V^h \text{ such that } & a(u^h, v^h) = l(v^h) \quad \forall v^h \in V^h, \\
a(u^h, v^h) &= \int_\Omega \nabla u^h \cdot \nabla v^h \, dx, \\
l(v^h) &= \int_\Omega f v^h \, dx + \int_{\Gamma_N} g v^h \, d\Gamma, \\
V^h &= \left\{ v^h = \sum_{i \in I} a_i \varphi_i + \sum_{i \in I_H} b_i H \varphi_i + \sum_{i \in I_F} c_i \varphi_i F_i; \ a_i, b_i, c_i \in \mathbb{R} \right\}
\end{aligned}
\]

and the one of the Lamé system is:

\[
\begin{aligned}
\text{Find } u^h \in V^h \text{ such that } & a(u^h, v^h) = l(v^h) \quad \forall v^h \in V^h, \\
a(u^h, v^h) &= \int_\Omega \sigma(u^h) : \varepsilon(v^h) \, dx, \\
l(v^h) &= \int_\Omega f v^h \, dx + \int_{\Gamma_N} g v^h \, d\Gamma, \\
\sigma(u^h) &= \lambda tr\varepsilon(u^h) I + 2\mu \varepsilon(u^h), \\
V^h &= \left\{ v^h = \sum_{i \in I} a_i \varphi_i + \sum_{i \in I_H} b_i H \varphi_i + \sum_{i \in I_F} c_i \varphi_i F_i; \ a_i, b_i, c_i \in \mathbb{R}^2 \right\}
\end{aligned}
\]

where \(I_F\) is the set of finite element nodes which are inside a disk centered on the crack tip and of a fixed radius \(r_2\) independent of the mesh parameter. Let us prove now the optimality of this method.

**Theorem 4** Assume that the displacement field \(u\), solution to Problem (1) (resp. Problem (2)) , satisfies Condition (3). Then, the following estimate holds

\[
\|u - u^h\|_{1, \Omega} \lesssim h \left( \|u - u_s\|_{2, \Omega} + \|u_s\|_{1, \Omega} + \|u_s\|_{2, \Omega \setminus B(x^*, r_2)} \right),
\]

where \(u^h\) is the solution to Problem (49) (resp. to Problem (50)).

**Proof:** Let \(\chi\) be a \(W^{2,\infty}\) cut-off function satisfying (11) such that \(r_1 < r_2\) and \(r_0 > \frac{r_2}{2}\). Let

\[
\chi^h = I^h \chi,
\]

be the interpolate of \(\chi\) on the \(P_1\) finite element method. Using the notation of Section 4, the following interpolation operator

\[
\Pi^h_S u = I^h u_v + \chi^h u_s,
\]
clearly satisfies \( \Pi_h u \in V^h \) for \( V^h \) defined by (49) (resp. by (50)) at least for \( h \) sufficiently small since \( r_1 < r_2 \). Then,

\[
\|\Pi_h u - \Pi_h^S u\|_{1,\Omega} = \|(\chi - \chi^h)u_s\|_{1,\Omega} \\
\leq \|(\chi - \chi^h)\|_{W^{1,\infty}} \|u_s\|_{1,\Omega} \\
\lesssim h\|\chi\|_{W^{2,\infty}} \|u_s\|_{1,\Omega},
\]

using a classical error estimate on the interpolation of \( \chi \) with a \( P_1 \) finite element method (see for instance [20]). Thus, using the estimates established in section 4, one has

\[
|u - \Pi_h^S u|_{1,\Omega} \leq |u - \Pi_h u|_{1,\Omega} + \|\Pi_h u - \Pi_h^S u\|_{1,\Omega} \\
\lesssim h\|u - \chi u_s\|_{2,\Omega} + h\|u_s\|_{1,\Omega} \\
\lesssim h\|u - u_s\|_{2,\Omega} + \|1 - \chi\|_{W^{2,\infty}} \|u_s\|_{1,\Omega} + \|u_s\|_{2,\Omega}\nabla B(x_*, r_2^2)\}
\]

Which ends the proof thanks to Céa’s lemma. \( \square \)

Note that this optimal convergence was observed in the numerical results presented on Fig. 8. An interpretation of the proof of Theorem 4 is that the standard Xfem is probably more optimal than the Xfem with a cut-off function because the cut-off function used in the proof is arbitrary. As a consequence, the error bound of the standard Xfem is less than the infimum taken on all the \( W^{2,\infty} \) cut-off functions satisfying (11). This is also corroborated with the result on Fig. 8. Of course, the standard Xfem is more expensive than the Xfem with a cut-off function since the number of enrichment degrees of freedom can be greatly higher.

**Concluding remarks**

In this paper we have obtained new advances in the analysis of Xfem methods. First, in contrast with [12] we provide optimal a priori error estimates. We also provide an a priori error estimate on the standard Xfem with fixed enrichment area which shows the optimality of this method. As far as we know, this is the first result of this kind for this method. An error estimate on the estimation of the stress intensity factors computed by the variant which uses a cut-off function is also established. We prove that the convergence order is \( O(h^{1/2}) \) which is confirmed by numerical experiments. This order is rather low compared to the one obtained with the J-integral (see [18, 33, 34, 28, 25]). However, it permits to have a first estimate without post-treatment of the solution. The numerical experiments show that the quality of the approximated stress intensity factors are very sensitive to the shape of the cut-off function. This suggest to investigate in the future the variant with a pointwise matching [25] or an integral matching [15, 11] which avoid the use of a cut-off function. Another interesting perspective is the generalization to 3D cracks where the computation of the stress intensity factors is more complex. It should be interesting to see if a variant with an integral matching or a cut-off function could be successfully adapted.
