Static output feedback sliding mode control design via an artificial stabilizing delay

Alexandre Seuret, Christopher Edwards, Sarah K. Spurgeon and Emilia Fridman

Abstract—It is well known that for linear, uncertain systems, a static output feedback sliding mode controller can only be determined if a particular triple associated with the reduced order dynamics in the sliding mode is stabilisable. This paper shows that the static output feedback sliding mode control design problem can be solved for a broader class of systems if a known delay term is deliberately introduced into the switching function. Effectively the reduced order sliding mode dynamics are stabilized by the introduction of this artificial delay.

Index Terms—Sliding mode control, output feedback, time delay systems, exponential stability, discretized Lyapunov-Krasovskii functionals, stabilizing delay.

I. INTRODUCTION

In many practical situations, all the states are not available to the controller. In some circumstances it is impossible or prohibitively expensive to measure all of the process variables. With this in mind, many authors have developed methods to control systems only using output feedback, of which one approach is the output feedback sliding mode control paradigm [5].

The idea developed in this paper is to broaden the class of systems for which a static output feedback based sliding mode controller can be developed based on a recent result from time delay systems. In [7], [11], the authors show that for some systems, the presence of delay can have a stabilizing effect. This affords the possibility of taking a system which is not stabilizable by static output feedback without delay and finding a constant delay $\tau$ strictly greater than 0 such that the system is stable. In this case, a stabilizing delay is introduced into the dynamics to effect output feedback stability.

This design concept is not new. Several authors have considered this possibility. For example in [15], [17], [18] it has been shown that introducing a delay in an output feedback controller can stabilize a system which cannot be stabilized without delay. This property has already been noted in the production of proteins in a cell [13]. When researchers try to model this production without delay, the solutions oscillate and do not correspond to the known physical behaviour. By introducing a delay corresponding to the intracellular transport by convection, the solutions correspond more closely to the known behavior.

The novelty in this paper is in overcoming the output feedback stabilizability assumption [2] in the design of sliding mode controllers by static output feedback. The authors propose a new switching function which contains an additional term which is linear in the delayed output. This is shown to be constructive in stabilizing the reduced order sliding mode dynamics. It is then shown that a sliding motion can be reached in finite time.

The article is organized as follows. The second section presents the problem formulation. Section three formulates the definition of a new sliding function which contains an artificial delay. In section four, the problem of exponential stability of the reduced order sliding motion with constant delay using discretized Lyapunov-Krasovskii functionals is solved. Section five deals with the exponential stabilization of non-delayed systems by a sliding mode controller including delay. In the last section, a numerical example demonstrates the design of the

gains and the effect of the choice of the delay in the sliding mode controller.

Throughout the article, the notation $P > 0$ for $P \in \mathbb{R}^{n \times n}$ means that $P$ is a symmetric and positive definite matrix. $[A_1 | A_2 | \ldots | A_n]$ is the concatenated matrix formed from the matrices $A_i$. The symbol $I_n$ represents the $n \times n$ identity matrix. The notations $| \cdot |$ and $\| \cdot \|$ refer to the Euclidean vector norm and its induced matrix norm, respectively. For any function $\phi$ from $C^1([-\tau, 0], \mathbb{R}^n)$, we denote $|\phi|_\tau = \sup_{s \in [-\tau, 0]}(|\phi(s)|)$.

II. PRELIMINARIES AND PROBLEM FORMULATION

Consider the linear uncertain system without delay

$$
\begin{align*}
\dot{x}(t) &= Ax(t) + B(u(t) + \psi(y(t))) \\
y(t) &= Cx(t)
\end{align*}
$$

(1)

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$ and $y(t) \in \mathbb{R}^p$ with $m < p < n$, corresponds to the state, control and output variables respectively. The function $\psi \in \mathbb{R}^m$ represents the matched disturbances and is assumed to satisfy:

$$
\|\psi(t)\| \leq \Psi_2(y(t))
$$

(2)

where $\Psi_2$ is a known function.

The matrices $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times m}$, $C \in \mathbb{R}^{p \times n}$ are assumed to be known. It is also assumed that the pair $(A, B)$ is controllable and the input and the output matrices $B$ and $C$ are full rank. In addition, it is assumed $\text{rank}(CB) = m$. Then from [2], [4], there exists a change of variables such that the system has the following representation:

$$
\begin{align*}
\dot{x}(t) &= \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ B_2 \end{bmatrix} (u(t) + \psi(y(t))) \\
y(t) &= \begin{bmatrix} 0 & T \end{bmatrix} x(t)
\end{align*}
$$

(3)

where $A_{11} \in \mathbb{R}^{(n-m) \times (n-m)}$, $B_2 \in \mathbb{R}^{n \times m}$ is nonsingular and $T \in \mathbb{R}^{p \times p}$ is an orthogonal matrix. In [2] a sliding surface

$$
S = \{ x \in \mathbb{R}^n : FCx(t) = 0 \}
$$

(4)

is proposed, where $F = F_2[K \ I_m]T^T$, $K \in \mathbb{R}^{m \times (p-m)}$ and $F_2 \in \mathbb{R}^{m \times m}$ is a nonsingular matrix. The sliding motion is governed by the choice of $K$. If a further coordinate change is introduced based on the nonsingular transformation $z = \hat{T}x$ with $\hat{T}$ defined by:

$$
\hat{T} = \begin{bmatrix} I_{n-m} & 0 \\ KC_1 & I_m \end{bmatrix}
$$

(5)

where $C_1 = \begin{bmatrix} 0_{(p-m) \times (n-p)} & I_{(p-m)} \end{bmatrix}$, then, as argued in [2], the dynamics of the reduced order sliding motion is governed by

$$
\dot{x}_1 = (A_{11} - A_{12}KC_1)x_1(t)
$$

(6)

The fictitious system $(A_{11}, A_{12}, C_1)$ is assumed to be output stabilizable i.e., there exist a matrix $K$ such that the matrix $A_{11} - A_{12}KC_1$ is Hurwitz. It is shown in [2] that a necessary condition for $(A_{11}, A_{12}, C_1)$ to be stabilizable is that the invariant zeros of $(A, B, C)$ lie in the open left half-plane. However the design of an output feedback gain $K$ such that the matrix $A_{11} + A_{12}KC_1$ is Hurwitz is not always straightforward and may be impossible. Consider for instance the system (6) with

$$
A_{11} = \begin{bmatrix} 0 & -2 \\ 1 & 0.1 \end{bmatrix}, \ A_{12} = \begin{bmatrix} -1 \\ 0 \end{bmatrix}, \ C_1 = \begin{bmatrix} 0 & 1 \end{bmatrix}
$$

which is from [1], [2]. In this case, the output feedback stabilization problem becomes the problem of finding a scalar $k$ such that the matrix $\begin{bmatrix} 0 & -2 - k \\ 1 & 0.1 \end{bmatrix}$ has strictly negative eigenvalues, which is clearly not possible. In this situation, some authors [1], [3], [5] have employed a compensator in order to stabilize the system. However, these methods increase the order of the controller and have an associated computational overhead both in terms of design and implementation. The proposed method seeks to introduce an artificial delay in the system such that the system can be stabilized by static output feedback without the need to introduce a compensator.

III. DESIGN OF A NEW SLIDING MODE SURFACE

In this section, the design of a new type of sliding surface will be discussed. The objective is to define a sliding surface of the form of (4) but which introduces a delay in the reduced order dynamics. Consider

$$
S' = \{ x \in \mathbb{R}^n : FCx(t) + F_\tau Cx(t-\tau) = 0 \}
$$

(7)

where as before the matrix $F = F_2[K \ I_m]T^T$ and where $F_\tau = F_2[K_\tau \ 0_m]T^T$, $K_\tau \in \mathbb{R}^{m \times (p-m)}$. Here,
without loss of generality, the matrices $F_2$ and $T$ are chosen as $I_m$. In (7), $\tau$ is an artificial, fixed and known delay which has to be chosen to stabilize the reduced order dynamics in the sliding mode and represents a design parameter. The existence of such a delay and constructive methods to choose it will be discussed in a latter section. Instead of (5), consider the coordinate change $x \mapsto T_\tau x$:

\[
\begin{align*}
\tilde{x}_1(t) &= x_1(t) \\
\tilde{x}_2(t) &= x_2(t) + KC_1 x_1(t) + K_\tau C_1 x_1(t - \tau)
\end{align*}
\]

By construction the switching function associated with $S'$ is $s(t) = \tilde{x}_2(t)$. This leads to:

\[
\begin{align*}
\dot{x}_1(t) &= (A_{11} - A_{12}K_1)\tilde{x}_1(t) \\
&\quad - A_{12} K_\tau C_1 \tilde{x}_1(t - \tau) + A_{12} \tilde{x}_2(t) \\
\dot{x}_2(t) &= (A_{21} + KC_1 A_{11})\tilde{x}_1(t) \\
&\quad + K_\tau C_1 A_{11} \tilde{x}_1(t - \tau) + (A_{22} + KC_1 A_{12}) \tilde{x}_2(t) \\
&\quad + K_\tau C_1 A_{12} \tilde{x}_2(t - \tau) - B_2 (u(t) + \psi(t)) \\
&\quad - (A_{22} + KC_1 A_{12})K_1 \tilde{x}_1(t) - (KC_1 A_{12} K_\tau \\
&\quad + A_{22} K_\tau + K_\tau C_1 A_{12} K_1) \tilde{x}_1(t - \tau) - K_\tau C_1 A_{12} K_\tau C_1 \tilde{x}_1(t - 2\tau)
\end{align*}
\]

Remark 1: It is important to note that the system (8) is a particular delay system. Since the delay is artificially introduced in the sliding manifold, the delay $\tau$ is known and can be chosen to improve the stability of the closed-loop system.

Remark 2: The sliding mode dynamics are given by equation (8) with $\tilde{x}_2(t) = 0$. This is a retarded system, where the delay is known and can be selected to stabilise, or enhance the stability of, the reduced order sliding motion.

Remark 3: Note that the range space dynamics given in (9) contain several delayed terms and two different delays, $\tau$ and $2\tau$. However $\tau$ is a design parameter in the particular formulation presented here, and thus $\tau$ is perfectly known to the controller.

The last two lines of equation (9) only depend on the known output information, $\tilde{x}_2$ and $C_1 \tilde{x}_1$, where $T^\top y = [C_1 \tilde{x}_1, \tilde{x}_2]$, and thus the following output feedback control law can be defined:

\[
\begin{align*}
u(t) &= -(B_2)^{-1} \left\{ (A_{22} + KC_1 A_{12}) \tilde{x}_2(t) \\
&\quad + K_\tau C_1 A_{12} \tilde{x}_2(t - \tau) \\
&\quad - (A_{22} + KC_1 A_{12}) (C_1 \tilde{x}_1(t)) \\
&\quad - K_\tau C_1 A_{12} K_\tau (C_1 \tilde{x}_1(t - 2\tau)) \\
&\quad - G_1 \tilde{x}_2(t) + \nu(t) - (KC_1 A_{12} K_\tau \\
&\quad + A_{22} K_\tau + K_\tau C_1 A_{12} K_1 (C_1 \tilde{x}_1(t - \tau))) \right\}
\end{align*}
\]

where $\tilde{x}_i(t) = 0$, $t < 0$, $i = 1, 2$ and $G_1$ is a Hurwitz matrix. The term $\nu$ is the discontinuous injection defined by

\[
\nu(t) = \begin{cases} 
\rho(t,y) \frac{Q_2 \tilde{x}_2(t)}{\|Q_2 \tilde{x}_2(t)\|} & \text{if } \tilde{x}_2(t) \neq 0 \\
0 & \text{otherwise}
\end{cases}
\]

where $Q_2$ is a symmetric positive definite matrix in $\mathbb{R}^{m \times m}$ and

\[
\rho = \|B_2\| \Psi_2(y(t)) + \delta
\]

where $\delta$ is a positive scalar gain. The closed loop system satisfies the following equations

\[
\begin{align*}
\dot{x}_1(t) &= (A_{11} - A_{12}K_1)\tilde{x}_1(t) \\
&\quad - A_{12} K_\tau C_1 \tilde{x}_1(t - \tau) + A_{12} \tilde{x}_2(t) \\
\dot{x}_2(t) &= (A_{21} + KC_1 A_{11})\tilde{x}_1(t) + A_{22} \tilde{x}_2(t) + G_1 \tilde{x}_2(t) \\
&\quad + K_\tau C_1 A_{11} \tilde{x}_1(t - \tau) - \nu(t) + B_2 \psi(y(t))
\end{align*}
\]

Remark 4: Note that the control law (10) does not have a heavy computational overhead.

IV. EXPONENTIAL STABILITY OF THE CLOSED LOOP SYSTEM

A. Exponential stability of the reduced order system

Consider the linear system with constant delay:

\[
\begin{align*}
\dot{x}_1(t) &= A_0 \tilde{x}_1(t) + A_1 \tilde{x}_1(t - \tau)
\end{align*}
\]

where $\tilde{x}_1 \in \mathbb{R}^{(n-m)}$ is the state and where $A_0 = A_{11} - A_{12}K_1$ and $A_1 = A_{12} K_\tau K_1$ are constant matrices with appropriate dimensions. System (14) represents the dynamics of the reduced order system (8) when $\tilde{x}_2(t) = 0$. Therefore, the sliding surface (7) underpins the stabilization of the sliding mode dynamics by using the delayed term $A_{12} K_\tau C_1 x_1(t - \tau)$.

System (14) is said to be exponentially stable [14], [16] with a decay rate $\alpha > 0$ and an exponential gain $\beta \geq 1$ if the following exponential bound holds:

\[
|\tilde{x}_1(t; t_0, \phi)| < \beta |\phi|_{\mathcal{C}^1} e^{-\alpha (t-t_0)},
\]

where $\tilde{x}_1(t; t_0, \phi)$ is the solution of (14), starting at time $t_0$ from the initial function $\phi \in \mathcal{C}^1$. Note that both $\alpha$ and $\beta$ must be independent of $\phi$.

Consider the change of variable $x_\alpha(t) = e^{\alpha t} \tilde{x}_1(t)$ as in [19], [21]. Effectively, asymptotic convergence of the $x_\alpha$ states implies exponential convergence of
\( \dot{x}_1 \) at a prescribed rate. Then it is easy to see that in the case of constant delay, equation (14) becomes

\[
\dot{x}_\alpha(t) = (A_0 + \alpha I_N)x_\alpha(t) + e^{\alpha \tau} A_1 x_\alpha(t - \tau)
\] (16)

Consider the following theorem based on the \( N \) discretized Lyapunov-Krasovskii functional proposed in [11].

**Theorem 1:** System (14) is exponentially stable with the decay rate \( \alpha \) if there exist \((n-m) \times (n-m)\) matrices \( P_1 > 0, P_2, P_3, S_p = S_p^T, Q_p, R_{pq} = R_{pq}^T, p,q = 0, ..., N \), which satisfy the LMI conditions (17) and (18) with \( h = \tau/N \)

\[
\Pi_\alpha = \begin{bmatrix}
\Xi_\alpha & D^s

- R_d - S_d & 0

-3S_d
\end{bmatrix} < 0
\] (17)

and

\[
P_1^* \hat{Q} \tilde{R} + S_N > 0
\] (18)

where the matrix \( \Xi_\alpha \) is given by

\[
\Psi_\alpha = P^T \begin{bmatrix}
0_n & e^{\alpha \tau} A_1

- \hat{S}_N
\end{bmatrix}
\]

and where \( \Psi_\alpha \) is given by

\[
P^T \begin{bmatrix}
0_n & A_0 + \alpha I_N - I_n

Q_1

0_n
\end{bmatrix} + \begin{bmatrix}
0_n & A_0 + \alpha I_N - I_n

Q_1

0_n
\end{bmatrix}^T P
\]

where

\[
\hat{Q} = \begin{bmatrix}
Q_0 & Q_1 & \cdots & Q_N
\end{bmatrix},
\]

\[
\hat{S} = \text{diag}(1/h S_0, 1/h S_1, \cdots, 1/h S_N),
\]

\[
\tilde{R} = \begin{bmatrix}
R_{00} & R_{01} & \cdots & R_{0N}

R_{10} & R_{11} & \cdots & R_{1N}

\vdots & \vdots & \ddots & \vdots

R_{N0} & R_{N1} & \cdots & R_{NN}
\end{bmatrix},
\]

\[
P = \begin{bmatrix}
P_1 & 0_n

P_2 & P_3
\end{bmatrix}
\]

and where for \( i, j = 1, ..., N \)

\[
S_d = \text{diag}(S_0 - S_1, S_1 - S_2, ..., S_{N-1} - S_N),
\]

\[
R_{dij} = h(R_{(i-1)(j-1)} - R_{ij}),
\]

\[
R_d = \begin{bmatrix}
R_{00} & R_{01} & \cdots & R_{0N}

R_{10} & R_{11} & \cdots & R_{1N}

\vdots & \vdots & \ddots & \vdots

R_{N0} & R_{N1} & \cdots & R_{NN}
\end{bmatrix},
\]

\[
D^s = \begin{bmatrix}
D_1^s & D_2^s & \cdots & D_N^s
\end{bmatrix},
\]

\[
D_i^s = \begin{bmatrix}
(R_{q(i-1)} - R_{qj}) - (Q_{j-1} - Q_i)

h/2(Q_{j-1} + Q_i)

-2/Q_{j-1} - Q_i

h/2(R_{N(j-1)} + R_{Nj})
\end{bmatrix},
\]

**Proof:** Consider the following Lyapunov-Krasovskii functional:

\[
V_\alpha(t) = x_\alpha^T(t) P_1 x_\alpha(t) + 2x_\alpha^T(t) \int_{-\tau}^{0} Q(\xi)x_\alpha(t + \xi)d\xi + \int_{-\tau}^{0} x_\alpha^T(t + \xi) S(\xi)x_\alpha(t + \xi)d\xi
\]

where \( P_1 > 0, Q(\xi) \in \mathbb{R}^{(n-m) \times (n-m)}, R(\xi, \xi) = R^T(\xi, \xi) \in \mathbb{R}^{(n-m) \times (n-m)}, S(\xi) \in \mathbb{R}^{(n-m) \times (n-m)}, \) and \( Q, R, S \) are continuous matrix functions. From [12] (p. 185) \( V_\alpha \) is positive definite if the LMI (18) holds. Then the proof follows along the lines of [7] using a descriptor representation [9] and \( \mathcal{G}_\text{discretization} [11]. \) It follows that \( x_\alpha \) converges asymptotically to the solution \( x_\alpha = 0 \) and consequently, the variable \( x \) converges exponentially to the solution \( x = 0 \) with the decay rate \( \alpha \). See the Appendix for more details.

**Remark 5:** Note that Theorem 1 is an extension of Theorem 2.1 from [7] to the exponential stability case. However the exponential stability considerations allow the performance and the convergence of the solutions to be characterized, which will be efficient for the design of the output feedback controller.

**Remark 6:** In the definition of the delayed sliding manifold (7), the delay is chosen to be constant. If for some reason the chosen delay needs to be time-varying, then a time-varying gain \( 1 - \hat{\tau}(t) \) will appear in the control law and the change of variables \( x \to x_\alpha \) will affect system (16) as the exponential gain will also be time-varying. However this situation can also be dealt with: see for example [19] or [20].

### B. Illustrative example

Consider system (14) [8], [10] with

\[
A_0 = \begin{bmatrix}
0 & 1 \\
-2 & 0.1
\end{bmatrix}, \quad A_1 = \begin{bmatrix}
0 & 0 \\
0 & 1
\end{bmatrix}
\]

As in [8], Theorem 1 cannot guarantee that this system is asymptotically stable, i.e. for \( \alpha = 0 \), if the delay is less than \( \tau_{\text{min}} = 0.11 \) s. The relationship between the delay \( \tau \) and the maximum admissible decay rate \( \alpha \) is given in Figure 1. The maximal decay rate \( \alpha \) results from the following optimization problem (see the Appendix, section B for more
Note that the ‘optimal delay’ is relative to the number of discretizations \( N \) is increased. This is due to the fact that when \( N \) increases, the degree of freedom to define the Lyapunov-Krasovskii functional also increases. Note that for all the discretizations, there exists a optimal delay which corresponds to the maximal decay rate. In a system where the delay can be chosen, as in system (13) presented in Section III, this form of graph can help to determine the optimal delay. Compared to the asymptotic result proposed in [8], Theorem 1 allows the existence of an optimal delay to be shown. This delay corresponds to the best performance in terms of stability.

**Remark 7:** Note that the ‘optimal delay’ is relative to the number \( N \) of discretizations used in Theorem 1. In Figure 1 the optimal delay when \( N = 1 \) is different from the one when \( N = 2 \). In the sequel the statement ‘optimal delay’ will be used to express the delay which corresponds to the fastest decay rate \( \alpha \) with respect to a certain level of discretization.

**C. Stabilization of the closed loop system**

This section focusses on the stability of the whole system (13). In particular, it needs to be established that \( \tilde{x}_2 = 0 \) in finite time, i.e. a sliding motion is achieved.

**Theorem 2:** System (13) is exponentially stable for given output feedback gains \( K \) and \( K_\tau \) with decay rate \( \alpha \) if there exist \( P_1 > 0, P_2, P_3, S_p = S_p^T, Q_p, R_{pq} = R_{qp}^T, p, q = 0, \ldots, N \) in \( \mathbb{R}^{(n-m)\times(n-m)} \) and \( Q_2 > 0 \in \mathbb{R}^{m\times m} \) which satisfy the LMI condition (21) and (18) with \( h = \tau / N \)

\[
\begin{bmatrix}
\Pi_\alpha
\end{bmatrix}
\begin{bmatrix}
(A_{21} + KC_1A_{11})^TQ_2 + P_1A_{12}
\end{bmatrix}
\begin{bmatrix}
e^{\alpha \tau(K_\tau C_1A_{11})}Q_2
\end{bmatrix}
\begin{bmatrix}
0_{N\times(n-m)\times m}
0_{N\times(n-m)\times m}
\end{bmatrix}
* Q_2G_1 + G_1^TQ_2 + 2\alpha Q_2
\end{bmatrix} < 0
\]  

(21)

where the matrix \( \Pi_\alpha \) is given by (19) and where \( A_0 = A_{11} - A_{12}KC_1 \) and \( A_1 = -A_{12}KC_1 \).

**Proof:** Consider new variables \( \tilde{x}_{1\alpha}(t) = \tilde{x}_1(t)e^{\alpha t} \) and \( \tilde{x}_{2\alpha}(t) = \tilde{x}_2(t)e^{\alpha t} \). The new closed-loop system satisfies the following equations:

\[
\begin{align*}
\dot{\tilde{x}}_{1\alpha}(t) &= (A_{11} - A_{12}KC_1 + \alpha I_{n-m})\tilde{x}_{1\alpha}(t) - e^{\alpha \tau}A_{12}K_\tau\tilde{C}_1\tilde{x}_{1\alpha}(t - \tau) + A_{12}\tilde{x}_{2\alpha}(t) \\
\dot{\tilde{x}}_{2\alpha}(t) &= (A_{21} + KC_1A_{11})\tilde{x}_{1\alpha}(t) + e^{\alpha \tau}K_\tau C_1A_{11}\tilde{x}_{1\alpha}(t - \tau) + (G_1 + \alpha I_m)\tilde{x}_{2\alpha}(t) - e^{\alpha \tau}(\nu(t) - B_2\psi(y(t)))
\end{align*}
\]

(22)

Consider the Lyapunov-Krasovskii functional

\[
V_\alpha(t) = V_{1\alpha}(t) + V_{2\alpha}(t)
\]

where \( V_{1\alpha} \) is defined in (20) and where

\[
V_{2\alpha}(t) = x_{2\alpha}^T(t)Q_2x_{2\alpha}(t)
\]

From [7] and following the line of the proof proposed in the appendix, differentiating \( V_{1\alpha} \) along the trajectory of (22a) leads to the following inequality:

\[
\begin{align*}
\dot{V}_{1\alpha} &\leq \xi_t^T(t)\Xi_\alpha \xi(t) - \int_0^1 \phi_t^T(\beta)S_\alpha\phi(\beta)d\beta \\
&\quad - \int_0^1 \int_0^1 \phi_t^T(\beta)R_\alpha\phi(\gamma)d\beta d\gamma \\
&\quad + 2\xi_t^T(t)\int_0^1 [D^\alpha + (1 - 2\beta)D^m] \phi(\beta)d\beta \\
&\quad + \tilde{x}_{1\alpha}^T(t)P_1A_{12}\tilde{x}_{2\alpha}(t)
\end{align*}
\]

(23)

where \( \Xi_\alpha \) is defined in (19) and the functions \( \xi \) and \( \phi \) are defined in the appendix.

Differentiating \( V_{2\alpha} \) along the trajectory of (22a) leads to:

\[
\begin{align*}
\dot{V}_{2\alpha} &\leq \tilde{x}_{2\alpha}^T(t)(G_1^TQ_2 + Q_2G_1 + 2\alpha I_m)\tilde{x}_{2\alpha}(t) \\
&\quad + \tilde{x}_{2\alpha}^T(t)Q_2[(A_{21} + KC_1A_{11})\tilde{x}_{1\alpha}(t) \\
&\quad + e^{\alpha \tau}K_\tau C_1A_{11}\tilde{x}_{1\alpha}(t - \tau) - e^{\alpha \tau}(\nu(t) - B_2\psi(y(t)))]
\end{align*}
\]

(24)

Then by combining (23) and (24) and by defining \( \xi'(t) = col\{\tilde{x}_{1\alpha}(t), \tilde{x}_{1\alpha}(t), \tilde{x}_{1\alpha}(t - \tau), \tilde{x}_{2\alpha}(t)\} \), the following inequality holds:
An ideal sliding motion takes place if the system satisfies the conditions from Theorem 2, the state $\bar{x}_1$ converges to the solution $\bar{x}_1 = 0$ with an exponential decay rate. It follows that the domain $\Omega$ is reached in finite time. Since the gain $\rho$ of the sliding function is defined as $\rho(t, y) = \Psi_2(y(t)) + \delta$, the following inequality holds:

$$\dot{V}_s(t) \leq -\eta \sqrt{V}_s(t)$$

This concludes the proof.

### E. Comments on the design of the output feedback gain

As usual, the problem of designing the output feedback gain is not straightforward. Moreover the LMI (21) is not in an appropriate form for synthesis purposes because the gains $K$ and $K_\tau$ appear in different ways in $\Xi_a$ than in $(KC_1A_{11})^TQ_2$ and $(K_\tau C_1A_{11})^TQ_2$. Congruence and other 'classical' LMI transformations will probably not facilitate constructive conditions. A constructive method at this time is to test the stability of the closed-loop system for a given set of values of $K$ and $K_\tau$ is discussed in the appendix.

### V. Extension to uncertain systems

Consider now the case when the system (3) is uncertain and time varying. Instead of the known matrices $A_{kl}$ for $k, l = 1, 2$, the following representation is introduced:

$$A_{kl}' = A_{kl}^0 + \sum_{i=1}^{M} \lambda_i(t) A_{ki}^i, \quad B_{l2}' = B_{l2} + \sum_{i=1}^{M} \lambda_i(t) B_{ki}^i$$

where $A_{11}^0 \in \mathbb{R}^{(n-m) \times (n-m)}$ and $B_{l2} \in \mathbb{R}^{m \times m}$ is non singular. The other matrices in (26) are assumed to have appropriate dimensions. It is assumed that, for all $i \in \{1, \ldots, M\}$, the pair of matrices $(A_{kl}^0 + A_{ki}^i, B_{ki}^i)$ is controllable. The scalar functions $\lambda_i$ are such that:

$$\forall i = 1, \ldots, M, \lambda_i(t) \in [0, 1], \sum_{i=1}^{M} \lambda_i(t) = 1. \quad (27)$$

As it is possible to remove some uncertainties, the system is rewritten as:

$$\dot{x}(t) = \begin{bmatrix} A_{k1}' & A_{k2}' \\ A_{k1}^0 & A_{k2}^0 \\ \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ B_{l2} \end{bmatrix} (u(t) + \psi_0(t, y, u))$$

$$y(t) = \begin{bmatrix} 0 & T \end{bmatrix} x(t)$$

where the matched uncertainties are represented by:

$$\psi_0(t, y, u) = B_{l2}^{-1} \left( \sum_{i=1}^{M} \lambda_i(t) (A_{ki}^i x_{2i}(t) + B_{ki}^i u(t)) \right) + \psi(t, y)$$

### Extension to uncertain systems

Corollary 1: An ideal sliding motion takes place in finite time. Since the gain $\rho$ of the sliding function is defined as $\rho(t, y) = \Psi_2(y(t)) + \delta$, the following inequality holds:

$$\dot{V}_s(t) \leq -\eta \sqrt{V}_s(t)$$

This concludes the proof.
This leads to
\[
\dot{x}_1(t) = (A_{11} - A_{12}K_{C_1})x_1(t) + A_{12}\ddot{x}_2 \\
- A_{12}K_{r}\dot{x}_1(t - \tau)
\]
\[
\dot{x}_2(t) = (A_{21} + KC_1A_{11})x_1(t) + K_{r}C_1A_{12}^{T}\dot{x}_2(t - \tau) \\
+ KA_{22} + KCA_{12}^{T}\ddot{x}_2(t) \\
+ K_{r}C_1A_{12}^{T}x_2(t - \tau) + B_{20}(u + \psi_0(t, y, u))
\]
\[
- (A_{22} + KCA_{12}^{T})K_{r}\dot{x}_1(t) \\
- K_{r}C_1A_{12}^{T}K_{r}C_1\dot{x}_1(t - 2\tau) - (KCA_{12}^{T}K_{r})C_1\dot{x}_1(t - \tau)
\]
\[
+ A_{22}K_{r} + K_{r}CA_{12}K_{r}C_1\dot{x}_1(t - \tau)
\]  
(29)

Note that the last two lines of the previous equation only depend on the output information and thus the following output feedback control law can be defined:

\[
u(t) = -(B_{20})^{-1}\{(A_{20}^{0} + KCA_{10}^{0})x_2(t) \\
+ KCA_{10}^{I}\dot{x}_2(t - \tau) + \nu - (A_{20}^{0})^{T} \\
+ KCA_{10}^{I}KCA_{1}x_1(t) - (KCA_{10}^{I})KCA_{12}K_{r} \\
+ A_{20}^{I}K_{r} + K_{r}CA_{10}K_{r}C_1\dot{x}_1(t - \tau) \\
- K_{r}C_1A_{12}K_{r}C_1\dot{x}_1(t - 2\tau) - G_{l}\dot{x}_2(t)\}
\]
(30)

where \( G_{l} \) is a Hurwitz matrix. The closed loop system satisfies the following equations:

\[
\dot{x}_1(t) = (A_{11} - A_{12}K_{C_1})x_1(t) \\
- A_{12}K_{r}\dot{x}_1(t - \tau) + A_{12}\ddot{x}_2(t)
\]
\[
\dot{x}_2(t) = G_{l}\dot{x}_2(t) + (A_{21} + KCA_{11})x_1(t) \\
+ K_{r}C_1A_{12}\dot{x}_1(t - \tau) - \nu + \psi_1(t, y, u)
\]  
(31)

where

\[
\psi_1(t, y, u) = \sum_{i=1}^{M}M_{i}\lambda_{i}(t)[KCA_{12}\dot{x}_2(t) \\
+ KCA_{12}KCA_{1}\dot{x}_1(t) \\
- KCA_{12}K_{r}C_1\dot{x}_1(t - \tau)] \\
+ \sum_{i=1}^{M}M_{i}\lambda_{i}(t - \tau)[KCA_{12}\dot{x}_2(t - \tau) \\
+ KCA_{12}KCA_{1}\dot{x}_1(t - \tau) \\
- K_{r}C_1A_{12}K_{r}C_1\dot{x}_1(t - 2\tau)] \\
+ B_{20}\psi_0(t, y, u)
\]

Since \( \psi_1 \) depends on \( t, y, u \), there exist positive functions \( \Psi_2 \) and \( \Psi_{21} \) such that:

\[
\|\psi_1(t, y, u)\| \leq \|B_{20}\|\Psi_2(t, y, u) + \Psi_{21}(t, y, u)
\]

The discontinuous control component \( \nu \) is still defined by (11) but the gain is now defined by:

\[
\rho(t, y, u) = \|B_{20}\|\Psi_2(t, y, u) + \Psi_{21}(t, y, u) + \delta
\]  
(32)

where \( \delta \) is a positive scalar gain.

Noting that equation (31) is polytopic and of the same form as (31), and that Theorem 2 is linear with respect to the matrix definition, the following result holds:

**Theorem 3**: System (31) is exponentially stable for given output feedback gains \( K \) and \( K_{r} \) with decay rate \( \alpha \) if there exist \( P_{1} > 0, P_{2}, P_{3}, S_{p} = S_{p}^{T}, Q_{p}, R_{pq} = R_{pq}^{T}, p, q = 0, ..., N \in \mathbb{R}^{(n-m)\times(n-m)} \) and \( Q_{2} > 0 \in \mathbb{R}^{m\times m} \) which satisfy the LMI condition (21) and (18) for all vertices \( i = 1, ..., M \) with \( h = \tau / N \).

Then the following corollary holds:

**Corollary 2**: An ideal sliding motion takes place in the domain \( \Omega \) given by

\[
\{(\tilde{x}_1, \tilde{x}_2) \in [t - \tau, t] \mapsto R^{m - m} \times R^{m} : \max_{i,j=1, ..., N} \{\|A_{21}^{i} + KCA_{11}^{i}\| + \|K_{r}C_1A_{11}^{j}\|\}| \tilde{x}_1(t - \tau) < \delta - \eta\}
\]

where \( \eta \) is a small scalar satisfying \( 0 < \eta < \delta \).

**Proof**: The proof is similar to the previous one. \( \square \)

VI. EXAMPLE

Consider the non-delayed system (3) with the definitions:

\[
A_{11} = \begin{bmatrix} 0 & -2 \\ 1 & 0.1 \end{bmatrix}, \quad A_{12} = \begin{bmatrix} -1 \\ 0 \end{bmatrix}, \quad A_{21} = \begin{bmatrix} -0.1 & -1 \end{bmatrix}, \quad A_{22} = \begin{bmatrix} 1 \end{bmatrix}, \quad C = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}
\]

As in [2], this system is not output stabilizable using traditional static (ie. non delayed output feedback). The objective remains here to design the controller (10) with appropriate gains \( K, K_{r} \in \mathbb{R} \) and an artificial delay \( \tau \) such that the closed-loop system is exponentially stable with decay rate \( \alpha \).

A. Design of the output feedback

This section proposes a method to obtain the optimal controller \( (K, K_{r}, \tau) \). The idea is to test if, for a set of values of \( K \) and \( K_{r} \), the LMIs from Theorem 2 have a solution and if it is possible to find the delay which ensures the greatest exponential decay rate.

After checking the resolution of the LMIs from Theorem 2, a solution can only be found when \( K \)
lies in the interval $[-6; 2]$ and $K_{\tau}$ in $[0; 8]$. For each value of the gains $K$ and $K_{\tau}$, an optimization process, detailed in Appendix B, is used to obtain the best value of $\alpha$ by tuning $\tau$ upwards from zero until the LMIs are not satisfied. The optimal delay will be the one which delivers the largest $\alpha$, using the same method as in Example 1. For this particular example the optimization problem is reduced to the following one:

$$\alpha_{max} = \max_{(K, K_{\tau}) \in [-6; 2] \times [0; 8]} \left\{ \max_{\tau \in [0, 1]} \alpha \right\}$$

such that (18) and (21) are satisfied.

![Graph](image)

Fig. 2. Maximum decay rate $\alpha$ with respect to $K$ and $K_{\tau}$ for $N = 1$

B. Simulation results

In the results which follow system (3) is controlled using (10) with $K = -2.23$, $K_{\tau} = 3.06$ and $\tau = 0.45$.

![Simulation results](image)

Fig. 3. Simulation results for $K = -2.23$, $K_{\tau} = 3.06$ and $\tau = 0.45$

Figure 3 shows the state, the input and the sliding function. The state converges exponentially to $x(t) = 0$ with an exponential decay rate $\alpha = 0.826$. The sliding function converges to $\tilde{x}_2 = 0$ in finite time. The evolution of the control signal is shown in Figure 3.

![Simulation results](image)

Fig. 4. Simulation results for different values of the delay $\tau$

In Figure 4, different delays are used to show robustness to changes in the delay. For too small values, e.g. $\tau = 0.01$, or too large a delay e.g. $\tau = 0.9$, the system is unstable. However when $\tau = 0.3$ or 0.6, which are sufficiently close to the optimal delay $\tau = 0.45$, the system is still stable. This behavior is consistent with the results of Example 1 (see Figure...
1). For given $K$ and $K_\tau$, exponential stability is ensured for delays sufficiently close to the optimal value of the delay, but the exponential decay rate is lower.

VII. CONCLUSION

A new sliding mode controller has been suggested for systems for which finding a traditional static output feedback sliding mode controller is not possible. The controller introduces a stabilizing delay in the closed loop system. The controller is simple and does not require heavy real-time computation. An example is used to demonstrate a method to design the gains and the delay of the controller. The robustness with respect to the delay has been shown in the example. A straightforward extension ensures robust stabilization with respect to disturbances and to parameter uncertainties.

REFERENCES

APPENDIX

A. Proof of Theorem 1

The following is not a new result, but the inclusion of a sketch of the proof of the discretization theorem is included to improve readability. Based on the results of [8], the first part of the proof of exponential stability consists of expressing the derivative of the Lyapunov Krasovskii functional appropriately. The next step of the proof focuses on the application of the discretization process of Gu [10].

Consider system (16) in a descriptor representation with the extended state vector $\vec{x}_\alpha(t) = col\{x_\alpha(t), \dot{x}_\alpha(t)\}$. This can be written as:

$$
\begin{bmatrix}
I_n & 0_n \\
0_n & 0_n
\end{bmatrix}
\begin{bmatrix}
\dot{x}_\alpha(t)
\end{bmatrix}
= 
\begin{bmatrix}
0_n & I_n \\
A_0 + \alpha I_n & -I_n
\end{bmatrix}
\begin{bmatrix}
x_\alpha(t)
\end{bmatrix}
+ 
\begin{bmatrix}
0_n \\
e^{\alpha \tau}A_1
\end{bmatrix}
\begin{bmatrix}
x_\alpha(t - \tau)
\end{bmatrix}
$$

The first term of the Lyapunov Krasovskii functional $V_{1\alpha}$ can be rewritten in the form:

$$
x_\alpha^T(t)P_1x_\alpha(t) = \bar{x}_\alpha(t)\begin{bmatrix}
I_n & 0_n \\
0_n & 0_n
\end{bmatrix}P\bar{x}_\alpha(t)
$$

where $P = \begin{bmatrix}
P_1 & 0_n \\
P_2 & P_3
\end{bmatrix}$. 

Differentiating the Lyapunov functional $V_{1a}$ along
the trajectories of (16) leads to:

$$
\dot{V}_{1a}(t) = 2x^T(t) \left[ P_1x(t) + \int_{-\tau}^{0} Q(\zeta)x(t + \zeta)d\zeta \right] + 2x^T(t) \int_{-\tau}^{0} Q(\zeta)\dot{x}(t \pm \zeta) \, d\zeta + 2\int_{-\tau}^{0} x^T(t) \left( R(s, \zeta)/ds \right) x(t \pm \zeta) \, d\zeta + 2\int_{-\tau}^{0} x^T(t + \zeta) S(\zeta)x(t + \zeta) \, d\zeta
$$

(33)

Rewriting the first term of (33) using the descriptor representation [6], and integrating by parts in (33), the following equality can be established:

$$
\dot{V}_{1a}(t) = \xi^T(t)\Xi_0 \xi(t) + 2x^T(t) \int_{-\tau}^{0} Q(\zeta)x(t + \zeta) \, d\zeta - \int_{-\tau}^{0} x^T(t + \zeta) S(\zeta)x(t + \zeta) \, d\zeta - \int_{-\tau}^{0} x^T(t + s) \left( \frac{\partial}{\partial \zeta} R(s, \zeta) + \frac{\partial}{\partial \tau} R(s, \zeta) \right) x(t \pm \zeta) \, ds \, d\zeta + 2x^T(t) \int_{-\tau}^{0} [-Q(\zeta) + R(0, \zeta)] x(t \pm \zeta) \, d\zeta - 2x^T(t - \tau) \int_{-\tau}^{0} R(-\tau, \zeta)x(t \pm \zeta) \, d\zeta
$$

(34)

where $\xi(t) = \text{col}\{\dot{x}(t), x(t - \tau)\}$ and $\Xi_0$ has the form in (19) with $Q(0), Q(-\tau), S(0)$ and $S(-\tau)$ instead of $Q_0, Q_N, S_0$ and $S_N$ respectively. The Lyapunov functional is now expressed in an appropriate representation to apply the discretization.

The discretization divides the delay interval $[-\tau, 0]$ into $N$ segments $[\theta_p, \theta_{p-1}], p = 1, \ldots, N$ of equal length $h = \tau/N$. This divides the square $[-\tau, 0] \times [-\tau, 0]$ into $N \times N$ small squares $[\theta_p, \theta_{p-1}] \times [\theta_p, \theta_{p-1}]$. Each small square is further divided into two triangles.

The continuous matrix functions $Q(\zeta)$ and $S(\zeta)$ are chosen to be linear within each interval and the continuous matrix functions $R(s, \zeta)$ is chosen to be linear within each triangle. The proposed matrix functions are:

$$
Q(\theta_p + \beta h) = (1 - \beta)Q_{p} + \beta Q_{p-1},
$$

$$
S(\theta_p + \beta h) = (1 - \beta)S_{p} + \beta S_{p-1},
$$

$$
R(\theta_p + \beta h, \theta_q + \gamma) = \begin{cases} 
(1 - \beta)R_{p} + \gamma R_{p-1(q-1)} + (\beta - \gamma)R_{p-1(q-1)} & \beta \geq \gamma \\
(1 - \gamma)R_{p} + \beta R_{p-1(q-1)} + (\gamma - \beta)R_{p-1(q-1)} & \beta \leq \gamma 
\end{cases}
$$

for $0 \leq \beta \leq 1$ and $0 \leq \beta \leq 1$. Simple definitions of the derivative of the matrix functions can be obtained which are, for appropriate $p$ and $q$:

$$
\dot{Q}(\zeta) = 1/h(S_{p-1} - S_p),
$$

$$
\dot{Q}(\zeta) = 1/h(Q_{p-1} - Q_p),
$$

$$
\frac{\partial}{\partial s} R(s, \zeta) + \frac{\partial}{\partial \zeta} R(s, \zeta) = 1/h(R_{p-1(q-1)} - R_{p})
$$

(35)

Thus, the Lyapunov Krasovskii functional is completely determined by the matrices $P_1, S_p, Q_p$ and $R_{p}, q = 0, \ldots, N$. From [12], the condition $V_{1a} \geq C ||x_a||$ is satisfied if LMI (18) is satisfied. Using conditions (35), the following equations hold:

$$
2x^T(t) \int_{-\tau}^{0} Q(\zeta)x(t + \zeta) \, d\zeta = 2x^T(t) \sum_{p=1}^{N} \int_{0}^{1} [(1 - \beta)Q_p + \beta Q_{p-1}] x(t^p) \, d\beta
$$

$$
= 2x^T(t) \sum_{p=1}^{N} \int_{0}^{1} [(1 - \beta)Q^a_p + \beta (Q^a_p - Q^a_{p-1})] x(t + \theta_p + \beta h) \, d\beta
$$

where $t^p = t + \theta_p + \beta h$, $Q^a_p = (Q_p + Q_{p-1})/2$ and $Q^a_p = (Q_p - Q_{p-1})/2$. Then equations (19), (34) and (35) imply [12]:

$$
\dot{V}_{1a}(t) = \xi^T(t)\Xi_0 \xi(t) - \int_{0}^{1} \phi(\beta) \dot{S}_\zeta \phi(\beta) d\beta
$$

$$
- \int_{0}^{1} \phi(\beta) R(\beta) \phi(\gamma) d\beta \dot{\gamma}
$$

$$
+ 2\zeta(t) \int_{0}^{1} [D^s + (1 - 2\alpha)D^a] \phi(\beta) d\beta
$$

where $\phi(\beta) = \text{col}\{x(t - h + \beta h), x(t - 2h + \beta h), \ldots, x(t - Nh + \beta h)\}$. Applying Proposition 5.21 from [12], it can be concluded that $\dot{V}_{1a}(t) < 0$ if LMI (17) is satisfied.

B. Optimization programs

The following table presents a schematic of the optimization program developed for Theorem 1 and 2. The variables $\epsilon_\tau$ and $\epsilon_K$ represent the grid size used during the search.
