Running head: Economic impact of climate variability

\*: Corresponding author: J. Robinson. Seychelles Fishing Authority, P.O. Box 449, Fishing Port, Mahé, Seychelles; tel. +248 670 338; [jrobinson@sfa.sc](mailto:jrobinson@sfa.sc)

25 ABSTRACT: Many small island states have developed economies that are strongly dependent  
26 on tuna fisheries. Consequently, they are vulnerable to the socio-economic effects of climate  
27 change and variability, processes that are known to impact upon tuna fisheries distribution and  
28 productivity. The aim of this study was to assess the impacts of climate oscillations on the  
29 tuna-dependent economy of Seychelles. Using a multiplier approach, the direct, indirect and  
30 induced economic effects of the tuna industry declined by 58%, 34% and 60%, respectively,  
31 in 1998, the year of a strong warming event in the western Indian Ocean. Patterns in tuna  
32 purse seine vessel expenditures in port were substantially modified by strong climate  
33 oscillations. A cointegration time-series model predicted that a 40% decline in tuna landings  
34 and transshipment in Port Victoria, a value commensurate with that observed in 1998, would  
35 result in a 34% loss for the local economy. Of several indices tested, the Indian Oscillation  
36 Index was the best at predicting the probability of entering a regime of low landings and  
37 transshipment. In 2007, a moderate climate anomaly was compounded by prior overfishing to  
38 produce a stronger than expected impact on the fishery and economy of Seychelles. The  
39 effects of fishing and climate variability on tuna stocks are complex and pose significant  
40 challenges for fisheries management and the economic development of countries in the Indian  
41 Ocean.

## 1. INTRODUCTION

Many countries, particularly small island developing states (SIDS), rely heavily on fisheries for economic development (Weber 1993; Bellwood et al. 2003; Zeller et al. 2006). For island states that are dependent on highly migratory and shared fish stocks, climate change poses significant challenges for effective governance and the maintenance of economic opportunities and benefits (Miller 2007). Developing countries are vulnerable to climate change due to their high reliance on fisheries and poor adaptive capacity (Allison et al. 2009). Building potential for adaptive capacity at sector and national levels will be enhanced through knowledge of the mechanisms linking physical and socio-ecological systems and the economic impacts of variability and change.

Climate variability operates on seasonal, inter-annual, or decadal time scales and affects numerous biological and ecological processes (Stenseth et al. 2002). El Niño Southern Oscillation (ENSO) events impact ecosystem processes across the globe and are the major phenomena driving inter-annual ocean climate variability (Glantz 1996). The ENSO signal propagates in the Indian Ocean (Nicholson 1997) and is manifested as sea surface temperature and heat storage anomalies (Tourre & White 1995). Inter-annual climate variability in the Indian Ocean also results from coupled ocean-atmosphere-land interactions that operate independently of the ENSO forcing originating in the Pacific (Webster et al. 1999; Marsac 2006). The Indian Ocean zonal dipole mode (IOD; Saji et al. 1999; Webster et al. 1999) is a “basin-scale pattern of surface and subsurface temperature that seriously affects the inter-annual climate anomalies of many nations around the Indian Ocean rim” (Meyers et al. 2007). The positive or negative IOD events may occur in the same years as ENSO, such as in 1998, or in the absence of that oscillation. ENSO and IOD processes have a profound effect on tuna fisheries in the region (Marsac 1991; Marsac & Le Blanc 1998; Ménard et al. 2007, Marsac

2008). The 1997-98 warm event, which coincided with one of the strongest ENSO events in the last century acting in phase with a positive IOD event, caused dramatic temperature and wind stress anomalies in the equatorial Indian Ocean (Murtugudde et al. 2000). Coincidentally, the distribution of the purse-seine tuna fishery was drastically modified, especially at the beginning of 1998 during the peak phase of the El Niño (Marsac & Le Blanc 1999). The usual fishing grounds of the western Indian Ocean (WIO) basin were deserted and the fleets underwent a massive shift to the eastern basin, as far as 100°E, a longitude never before reached by vessels based in the WIO (Marsac & Le Blanc 1999) (Fig. 1). Consequently, many vessels operated from Asian ports (notably Phuket, Thailand) and landings and vessel activity in Port Victoria (PV), Seychelles, decreased substantially, resulting in economic impacts for the fishing industry (Payet 2005). The eastward shift of the purse-seine tuna fleet (PSTF) during the 1997-98 warm event was mediated through changes in the behaviour of target tuna species and its effects on the fishery catch-per-unit-effort (CPUE). Of major concern to the tuna economy of Seychelles is the prediction that ENSO anomalies may increase in frequency and severity in relation to climate change (Timmermann et al. 1999).

The synchronies between climate oscillations and CPUE argue for a non-lagged effect of warm events on the catchability of tuna rather than for complex changes in the production regime, whereby anomalous thermocline depths associated with warm events in the WIO deepen the habitat for tuna and reduce their catchability to the purse-seine gear (Ménard et al. 2007). The modification of habitat for the surface swimming tuna species (particularly yellowfin tuna, *Thunnus albacares*) produced a change in behaviour, the fish undergoing a vertical migration to the deeper thermocline to forage. By contrast, in the eastern basin of the Indian Ocean, biological enrichment occurred through upwelling, keeping tuna in the surface layer and increasing their catchability (Marsac and Le Blanc 1999; Ménard et al. 2007).

97

98 Centrally located relative to the most productive tuna fishing grounds of the Indian Ocean, PV  
99 consolidated its position as the major regional hub early in the development of the purse-seine  
100 tuna fishery. The fishery is dominated by European-owned fishing vessels and under current  
101 fishing agreements, the European Union (EU) and ship-owners paid 4.7 million euros (€) and  
102 6.5 million € in 2005 and 2006, respectively, for access rights to the exclusive economic zone  
103 (EEZ) of Seychelles (source: DG MARE). Since 1992, annual catches by the purse-seine tuna  
104 fishery have varied between 250,000 and 400,000 t, with a trend of increasing annual growth  
105 up to 2007 (Fig. 2). The percentage of tuna caught by the fishery and landed or transhipped in  
106 PV has grown to over 90% in recent years. The development of the fishery peaked in 2006,  
107 when around 1.1 million tonnes (t) of tuna (54% skipjack tuna, *Katsuwonus pelamis*; 36%  
108 yellowfin tuna, *Thunnus albacares*; and 10% bigeye tuna, *Thunnus obesus*) were caught in the  
109 Indian Ocean (source: IOTC), constituting one quarter of the global catch.

110

111 The importance of tuna to the Seychelles economy has been enhanced through expansion in  
112 tuna canning capacity. Presently, the cannery (Indian Ocean Tuna Ltd) is one of the biggest in  
113 the world with an average daily processing capacity of 350 t. Co-owned by foreign investors  
114 (60%) and the Government of Seychelles (40%), it is a major employer of the domestic  
115 economy with 1,975 workers in March 2007, of which 1,149 were local workers (58%) and  
116 826 expatriates (42%). The company represents 19% of the formal employment in the private  
117 sector, and accounts for more than 90% of national exports (source: CBS). Most canned tuna  
118 exports are destined for Europe and Seychelles accounted for a 13% share of the European  
119 market in 2007. However, the position of Seychelles has been eroded by the rise of competing  
120 countries like Ecuador and Thailand, which rose above Seychelles in terms of European  
121 canned tuna market share after 2006. This erosion is partly due to the pervasive changes of

122 trade rules under the World Trade Organisation (WTO) and is also dependent on the  
123 availability of raw materials for processing.

124

125 The aim of this study is to assess the impacts of climate variability on the tuna-dependent  
126 economy of Seychelles. This assessment is achieved by crossing scientific knowledge on the  
127 linkages between climate and fisheries with economic models and several statistical methods  
128 (cluster analysis, cointegration, Markov-switching VECM) to analyse the relationships  
129 between climate indices and available economic data relating to the PSTF and fisheries-  
130 related industries.

131

132

## 2. METHODS

133 Economic data relating to the expenditure of the PSTF during calls to PV are collected by the  
134 Seychelles Fishing Authority (SFA) from the two vessel agents acting for the European-  
135 owned fleets. These data consist mainly of port call expenses, including taxes, dues, agency  
136 and administrative fees, and expenses relating to labour, ship chandlery, utilities, transport,  
137 health, accommodation, repair and maintenance. In addition, data on the total expenses paid  
138 by the vessels for fuel are also collected (Annex 1). Data were screened, verified and  
139 compiled by vessel type, quarter, year and expenditure categories. Purse-seine tuna fishery  
140 catch data were taken from the fisheries databases maintained by SFA and imported to the  
141 economic database. Due to errors with some vessel trip data for records prior to 1992, only  
142 data from 1992 to June 2008 were used in the study. In addition, we compiled economic data  
143 from other sources, namely; expenditures of the tuna canning factory (Indian Ocean Tuna,  
144 IOT), bunker rates of the Seychelles Petroleum Company (SEYPEC), trade data and  
145 consumer price index from the National Statistics Bureau (NSB), and currency exchange rates  
146 from the Central Bank of Seychelles (CBS).

147

148 We employed the following climate indices in the analyses: (1) the Dipole Mode Index  
149 (DMI), the east-west temperature gradient across the tropical Indian Ocean; (2) the Indian  
150 Oscillation Index (IOI), the difference in sea level pressure standardized anomalies between  
151 Seychelles and Darwin; (3) the Southern Oscillation Index (SOI), the difference in sea level  
152 pressure standardized anomalies between Tahiti and Darwin, and (4) the Western Tropical  
153 Indian Ocean sea surface temperature index (WTIO), the surface temperatures in the region  
154 50°E - 70°E, 10°S - 10°N.

155

### 156 **2.1. Estimating spillover effects using a multiplier approach**

157 The spillover effects of the expenditures by the PSTF in Seychelles were estimated using an  
158 input-output model and a multiplier approach (Leontief 1970). A model of the spillover  
159 effects was constructed (Fig. 3). The expenditure of fishing vessels landing or transhipping in  
160 PV is partly flooding into the national economy through the revenue transferred as wages or  
161 dividends (shareholders) to Seychellois households that is not saved or spent in imported  
162 goods. In addition to the direct (fleet) and indirect (cannery, government) expenses, a looping  
163 effect induced by the household expenditure can be estimated (left-hand bottom side of Fig.  
164 3). The standard multiplier impact is obtained by dividing the sum of direct, indirect and  
165 induced expenditure by total expenditure of the PSTF. Concerning the direct and indirect  
166 effects of landings/transhipments, all expenditure series were deflated by the consumer price  
167 index (CPI base 100 = 2001) and averaged on a yearly basis over the period 1992-2008.

168

169

170

171

## 2.2. Identifying climate effects on vessel expenditures

To determine the relative importance of seasonal versus inter-annual effects, vessel expenditure data were analysed using principal component analyses (PCA) based on quarterly observations between 1992 and 2007. Seventeen variables of port call expenses by the PSTF were selected as active continuous variables in the reduction process of the correlation matrix. Several other continuous variables (catches, effort, catch-per-unit-effort) were selected as illustrative variables in the process, i.e. simply projected on the factorial axes without any influence on the matrix reduction calculus. Six discrete variables (year, quarter, and the four climate indices: IOI, SOI, DMI and WTIO) were also used as illustrative variables and projected on the principal components. A hierarchical ascending classification was then applied on the basis of the Ward criterion (minimum inertia within the clusters and maximum inertia between the clusters), a break in the loss of total inertia (where total inertia is the sum of Eigen values for all principal components) between two steps of the clustering process indicating the number of clusters to be chosen. Finally, each cluster was described by the most discriminating variables selected by a statistic, with its associated probability calculated from a normal law test of means between the cluster and the sample.

## 2.3. Assessment of climate effects using cointegration and Markov analyses

### *Cointegration approach*

The relationship between cargo handling costs (CHC) and landings was tested through cointegration analysis (Johansen 1988), considering an unrestricted intercept and centred seasonal dummy variables as deterministic components of the model. After determining that the variables were not stationary (ADF and KPSS tests), the long-run relationships were studied through a multivariate Johansen approach and Granger's causality tests were carried out. Centred seasonal dummy variables were included

197 to take into account the seasonal behaviour of the variables. An unrestricted constant had to be  
 198 used in the model when the I(1) variables presented linear trends and an intercept different  
 199 from zero in the cointegration vectors. The Akaike Information Criterion (AIC) (Lütkepohl  
 200 2005) determined the number of lags included, 4 being the maximum. Additionally, the model  
 201 was checked for the absence of any statistical problems before determining the number of  
 202 cointegration relationships, including autocorrelation LM tests up to order 4 (Johansen 1995)  
 203 and the Jarque-Bera Normality test, with the results showing that the model was correctly  
 204 specified.

205

### 206 *MS-VECM*

207 Following a standard typology of shipping costs (Stopford 1997), we split the PSTF vessel  
 208 expenditures into cargo handling costs (CHC; costs varying with the levels of landings) and  
 209 the vessel or voyage costs (VC; i.e. avoidable fixed costs), of which the bunker costs  
 210 represented 86% on average. Two models were tested through different time-series  
 211 techniques; firstly, a cointegration approach of the relationship between landings and CHC  
 212 was tested; followed by a Markovian approach. Due to the fact that the long-run expenditure of  
 213 vessels at PV depended partly on the level of landings and transshipment of tuna, the equilibrium  
 214 between landings/transshipment and fishing effort was analysed, with gasoil expenditure (bunker costs)  
 215 used as a proxy of fishing effort. The influence of climate variability on the dynamics of this  
 216 relationship was then assessed.

217

218 The statistical analysis was carried out in a VAR context, allowing for regime change in terms  
 219 of a Markov process. We adopt a multivariate Markov-Switching model (MS-VECM) that  
 220 allows for regime switching mean equation parameters and variance-covariance matrix:

$$221 \quad \Delta x_t = \mu(z_t) + \sum_{j=1}^k A_j(z_t) \Delta x_{t-j} + \Pi(z_t) \Delta x_{t-1} + u_t \quad (3)$$

222 Where:

223  $x_t : (s_t, f_t^2, \dots, f_t^k)$ ;  $s_t$  = landings (in log terms);  $f_t^i$  = effort or input  $i$  ( $i=2, \dots, h$ ) at time  $t$ ;  $\mu(z_t)$

224 is a  $k$  dimensional vector of regime-dependent intercept terms;  $u_t \sim NID(0, \Sigma(z_t))$ ;

225  $\Pi(z_t) = \alpha\beta'$ ; the state  $z_t \in \{1, \dots, M\}$ ,  $M$  being the number of regimes.

226

227 To estimate this system, we proceeded as follows. First, the long-run relationship was determined  
 228 using the ML procedure suggested by Johansen (1988). No regime switching was taken into account  
 229 when obtaining estimates of the cointegrating vector. Then, we estimated the dynamic system above  
 230 using the EM algorithm that allows for two regimes of high and low volatility. We then proceeded  
 231 with the Markov chain estimation, allowing for two regimes. Determination of the lag length was  
 232 based on the Bayesian Information Criterion (BIC).

233

234 Finally, we assessed the impact of climate variability on the two regimes identified through  
 235 MS-VECM by conducting regression analyses to determine how variation in four climate  
 236 indices (described above) influences the probability of entering regime 1 (pstar). We  
 237 introduced three seasonal dummy variables in the regression model for the first three annual  
 238 quarters (D1, D2 and D3); a dummy variable was not introduced for the last quarter to avoid  
 239 multi-collinearity with the intercept. Then, we tested the influence of each climate index with  
 240 squared values of the indices used as explanatory variables in the regression analyses.

241

242

### 3. RESULTS

243

#### 3.1. Spillover effects estimated by a multiplier approach

244

245

246

Using the mean 2006 exchange rate (1€ = 6.93 Seychelles Rupees, SR) and with an annual  
 total (constant) expenditure of the tuna fleets valuing 240 million (M) SR<sub>2001</sub> (i.e. 35 M€;  
 average 1992-2006), the coefficient of induction was 1.57 (Fig. 4). In other words, every 100

247 SR spent by the PSTF in PV leads to a final net amount of 160 SR for the Seychelles  
248 economy. The average 1992-2008 direct expenditure of the fleet was valued at 203 MSR<sub>2001</sub>  
249 (29 M€) while the spillover (indirect and induced expenditures) effects were estimated at 181  
250 MSR<sub>2001</sub> (26 M€). Thus, a net induced contribution represents close to a 100% increase for the  
251 rest of the economy. Including IOT expenditures and their spillover effects, the coefficient  
252 rises to 2.50.

253  
254 The evolution of direct, indirect and induced effects over the study period reveals an erosion  
255 of the coefficient of induction, concurrent with the elevation of total expenditure due to the  
256 steady fuel price increase since 2000 (Fig. 4). Interestingly, all types of effects show an  
257 inflexion point in 1998, year of the main impacts of the 1997-98 warm event in the WIO (with  
258 a mechanical increase of the induction coefficient due to lower expenses that particular year).  
259 In 1998, the direct, indirect and induced effects declined by 58%, 34% and 60% (52%  
260 decrease overall), respectively, compared with a yearly growth trend of 17%, 4% and 11%  
261 (12% increase overall) for the same effects, respectively.

### 262 263 **3.2. Climate effects on purse seine vessel expenditures**

264 The (deflated) expenditure data varied in their seasonal and time patterns with some showing  
265 a strong seasonal variation and little change over time (factor 1), while others variables exhibit  
266 a combination of change between years and seasons, lying between the axes (Fig 5). Seasonal  
267 variation in expenditure is a response to seasonal variation in landings, which are pronounced  
268 during the second quarter when the PSTF mainly fishes in the Mozambique Channel and  
269 utilises other regional ports.

270

271 In projecting expenditure data as a factorial plan, 1998 is isolated from other years and  
272 clusters with the second quarter patterns of low expenditure and extreme values of two  
273 climatic indices, the Indian Oscillation Index (IOI) and the Western Tropical Indian Ocean sea  
274 surface temperature index (WTIO) (Fig. 6). This suggests that anomalous ocean-climate  
275 conditions produces a similar response in expenditure to that typically observed during the  
276 second quarter of the year. Cluster analysis of seasonally adjusted quarterly expenditure data  
277 yielded an optimal of 5 clusters and isolated 1994 and 1998 from the recurrent seasonal  
278 pattern, clustering most quarters from those years (55% of observations in the cluster  
279 compared to an average of 13%) and rejecting the null hypothesis of a random distribution.  
280 The level of tuna landings in this cluster was 53% lower than average and can be considered  
281 as the seasonally adjusted impact of the 1997-1998 warm event on the Seychelles tuna  
282 economy.

283

### 284 **3.3. Climate effects identified using cointegration and Markov analyses**

285 *Cointegration analysis of the relationship between landings and cargo handling costs (CHC)*

286 Prior to examining cointegration relationships, autocorrelation LM tests (4 lags; statistic: 3.10;  
287  $p=0.54$ ) and the Jarque-Bera normality test (statistic: 7.35;  $p=0.12$ ) determined that the model  
288 was specified correctly.

289

290 The number of cointegration vectors was determined using cointegration rank tests. Both the  
291 trace test and the maximum Eigenvalue test showed the existence of a cointegration  
292 relationship (Table 1). All the characteristic roots were inside the unit circle; as one of the  
293 characteristic roots was almost 1 ( $k-r=1$ ), one cointegration vector was selected.

294

295 Having shown cointegration between both variables, the cointegration relationship was  
 296 estimated, as follows:

$$297 \quad CHC_t - 1219592 - 116.12 \text{LANDING}_t = \varepsilon_t \quad (1)$$

298 CHC increase by 116 SR when total landings and transshipments in PV increase by 1 tonne (t).  
 299 This proportionality of 116 SR/t of fish landed/transhipped corresponds well with the average  
 300 unit price over the period. On average, with a standard level of 61,632 t landed/transhipped  
 301 per quarter (mean 1992:1-2008:2), the estimated CHC expenditure would be of 8,376,092  
 302 SR<sub>2001</sub>. Other things being equal, a 40% cut of landings caused by a warming event as extreme  
 303 as that of 1997-1998 would result in a total CHC expenditure of 5,513,492 SR<sub>2001</sub> per quarter,  
 304 equating to a 34% loss for the local economy.

305

### 306 *Markovian analysis of the relationship between bunker costs and landings/transshipment*

307 The long-term equilibrium between bunker costs and landings/transshipment was first tested in  
 308 logarithmic terms. Again, the cointegration analysis (Table 2) shows that we cannot reject the  
 309 hypothesis of a long-term equilibrium between the two variables.

310

311 The cointegration equation can be written as:

$$312 \quad \ln(\text{landing}) = 0.442 \log(\text{gasoil}) + 3.327 \quad (2)$$

313 \quad \quad \quad (0.071) \quad \quad \quad (1.215)

314 ( ): Standard deviation

315

316 The regimes are then identified in terms of levels of landings/transshipment. Regime 1  
 317 represents the higher level of landings/transshipment which mainly occurs during the third and  
 318 the fourth quarters. Regime 2 corresponds to the lower landings/transshipment of the second  
 319 quarter and also, frequently, of the first quarter (Fig. 7).

320

321 Over 42 observations, the probability of entering the first (high) regime ( $p^*$ ) is close to 0  
322 (lower than 0.05) for 16 observations and is close to 1 (greater than 0.95) for 21 observations.

323 The lowest values of  $p^*$  generally occur when the variation in landings/transshipment is  
324 strongly negative (11 observations over 15); this occurs mainly during the second quarter  
325 when the vessels often land in other regional ports (11 obs. out of 16 are second quarters).

326 Consequently, regime 2 can be interpreted as a low regime for landings at PV. While not  
327 defined by 3 quarters entering the low regime, 2007 was the only year since 1998 for which  
328 there were two consecutive quarters in regime 2.

329

330 The best model was obtained with the IOI, the other models exhibiting a lower level of  
331 significance (Table 3). With the WTIO, the model did not validate the significance of climate,  
332 even at a 90% level, and the results are not shown. For all the climate index models, the  
333 seasonal dummy variables exhibit the expected sign, i.e. negative for the second quarter and  
334 positive for the first and third quarters. In terms of the IOI index, any strong deviation from  
335 the mean decreases significantly the probability of entering the high regime of landings at PV.

336 Looking at the IOI values, the strongest deviations of the index were negative for the last  
337 quarter of 1997 and first quarter of 1998, during the strong ENSO episode. To a lesser extent,  
338 the SOI and DMI climate indices also have a negative and significant impact on the regime.

339 Any important variation of the climate index could have a depressing influence on  
340 landings/transshipments in Seychelles (i.e. entering regime 2).

341

342

#### 4. DISCUSSION

343 The findings of this study are suggestive of a link between climate variability and the tuna  
344 economy of Seychelles. While it is recognized that causality has not been demonstrated, the

345 coincidence of a severe warming event in late 1997 and 1998 (Murtugudde et al. 2000) with  
346 significant disruptions to the PSTF and loss of revenue for the national economy is  
347 compelling evidence for a climate effect. Within the period corresponding to our expenditure  
348 dataset (1992-2008) there have been several warming events in the WIO, some moderate  
349 (2003 and 2004-2005) and some relatively strong (1994 and 2006-2007), none of which have  
350 resulted in an PSTF expenditure response comparable to that experienced in 1997-1998. This  
351 pattern may be expected as moderate temperature anomalies in the Indian Ocean do not strongly  
352 affect the surface habitat of yellowfin tuna (Ménard et al. 2007). As strength of a climate  
353 anomaly appears critical in terms of the economic impact, future research should investigate  
354 thresholds to facilitate adaptive management responses.

355  
356 Although the underlying changes to the fishery differ, the economic impacts of the 1998  
357 warming event can be considered as an extended low season. In the Indian Ocean, the PSTF  
358 demonstrates a high level of spatial mobility as they follow seasonally varying patterns in  
359 abundance and accessibility to surface gear (Miller 2007). Seychelles normally experiences  
360 seasonal lows in landings and transshipment during the second quarter of the year, when the  
361 fleets target tuna in the northern Mozambique Channel and operate out of other regional ports.  
362 In other quarters, landings at PV are higher and generally stable between years. However, in  
363 1998, the 2<sup>nd</sup> quarter low season was bracketed by low levels of vessel expenditures in the 1<sup>st</sup>  
364 and 4<sup>th</sup> quarters, leading to depressed annual revenue.

365  
366 Economic impacts resulting from climate oscillations are acute compared to the chronic  
367 changes that may characterise climate regime shifts, which are also more difficult to measure  
368 or predict (Arnason 2007). After accounting for inflation and seasonal variation, all PSTF  
369 vessel expenditures were sensitive to the 1998 oscillation, the extent of which was dependent

370 on the relative strength of inter-annual trends in landings, transshipment and service unit costs.  
371 For the cargo handling costs, it was estimated that the 1998 episode had a negative impact of  
372 34% on the PSTF expenditure in PV, in line with the cut in landings and transshipment for that  
373 year and after taking into consideration the trend and seasonal components. Interestingly, this  
374 impact is comparable to ENSO impacts on the Chilean and Peruvian fishmeal fisheries, where  
375 the social welfare loss due to ENSO was estimated to be 42% below a normal year of  
376 reference (Sun et al. 2001).

377

378 The large declines of purse-seine CPUE and catch in late 2006 and early 2007 were  
379 disproportionate in relation to the moderate strength of the El Niño and IOD oscillations of  
380 that period. One hypothesis that has been proposed to explain this observation identifies a  
381 synergistic effect between stock levels and environmental anomalies. Stock assessments  
382 recently conducted under the auspices of the Indian Ocean Tuna Commission (IOTC Working  
383 Party on Tropical Tunas, October 2008, and the IOTC Scientific Committee, December 2008)  
384 concluded that the yellowfin tuna stock was overfished during the 2003 to 2006 period.  
385 During this period, the main fishing grounds were characterized by an anomalous decrease of  
386 the mixed layer depth (MLD), bringing tuna to the surface and resulting in increased  
387 catchability, fishing mortality and, consequently, a decline in stock biomass (Marsac 2008).  
388 By late 2006/early 2007, the reduced biomass may have acted in concert with a moderate  
389 climate oscillation, which increased the MLD, to depress CPUE and catch (IOTC-2007-SC-R;  
390 Marsac 2008). While the reductions in vessel expenditures in 2007 were not of the magnitude  
391 observed a decade or so earlier, this latest event highlights the complex and important  
392 relationship between climate and tuna fisheries. In particular, it demonstrates how coupled  
393 ocean-atmosphere oscillations influence the levels of fishing mortality through the  
394 modification of tuna habitat, which has important consequences for fisheries management.

395

396 Climate indices representing dominant climate patterns in the oceans can be good predictors  
397 of ecological processes (Bakun 1996; Stenseth et al, 2002; Hallett et al. 2007). In this study,  
398 we demonstrate that they can also be used to examine economic effects. In particular, the IOI  
399 has been shown to be robust in tracking warm and cold events in the Indian Ocean and their  
400 ecological impacts (Marsac & Le Blanc 1998; Ménard et al. 2007, Marsac 2008) and now, in  
401 this study, economic effects. The climate oscillations described by the IOI and SOI, and to a  
402 lesser extent the DMI, influenced the dynamics between landings/transshipment and gasoil  
403 consumption (as a proxy for fishing effort), whereby the indices predicted, in the short-term,  
404 the switching between the high and low regimes of these variables that were identified by a  
405 MS-VECM model. Any deviation of the square IOI value from average values decreases by  
406 nearly 10% the probability of being in a normal (high) landing regime, other things being  
407 equal. Given that climate oscillations operate on a range of spatial and temporal scales, and  
408 that their interrelationships are not fully understood, it is important to examine observations  
409 using a range of indices. As an example of this, a moderate impact on expenditures was  
410 observed in 1994 in the absence of an ENSO event. However, this year was possibly  
411 characterised by strong IOD event that resulted in warming anomalies in the western basin.  
412 While the classification of 1994 as an IOD event is still being debated, it potentially  
413 represents an example of an Indian Ocean climate oscillation acting independently of ENSO  
414 (Meyers et al. 2007).

415

416 Similar to many SIDS situated in productive tuna fishing zones, Seychelles has come to rely  
417 heavily on a 'tuna economy' as the world demand for tuna has grown steadily over recent  
418 decades (Campling et al. 2007; Campling & Havice 2007). The importance of the Seychelles  
419 tuna economy was, for the first time, estimated using a multiplier approach. However, beyond

420 the impact on the domestic wealth, of greater importance is the presence of the cannery for  
421 national employment, since it represents 19% of private sector employment and 6% of total  
422 employment. Landings to IOT create higher levels of employment than transshipment of frozen  
423 tuna from purse-seiners to reefers. Given that the availability of tuna in the area of the  
424 Seychelles EEZ is at the core of competitiveness for the canning industry, the socio-economic  
425 implications of climate oscillations are severe. As evidence, the warming episode of 1998  
426 resulted in major disruptions in IOT production and employment levels lasting for several  
427 months.

428  
429 Changes in the distribution and magnitude of fisheries resources will have important socio-  
430 economic consequences at national and regional levels (Arnason 2007, Miller 2007, Sun et al.  
431 2006). Climate change scenarios predict modification of skipjack tuna habitat and distribution  
432 in the equatorial Pacific with implications for the important tuna economies of Pacific island  
433 countries (Loukos et al. 2003). Considering commercially exploited species as a whole, catch  
434 potential is predicted to decline across the tropical oceans under climate change scenarios  
435 (Cheung et al. 2009), heightening the vulnerability that already characterises many tropical  
436 countries (Allison et al. 2009). While climate change and variability are two of many factors  
437 affecting fish stocks, not least of which is fishing pressure, their incorporation in population  
438 and bio-economic fisheries models will be increasingly important for assessment, prediction  
439 and management (e.g. Sun et al. 2006).

440  
441 Given that trade in tuna and tuna products is international, the socio-economic effects of  
442 climate variability in Seychelles are not limited to events in the WIO. Global price trends for  
443 tuna are sensitive to the effects of ENSO acting on tuna fisheries in other regions. For  
444 example, Taiwanese tuna purse seine fisheries in the south-western Pacific Ocean experienced

445 the effects of overproduction and a 50% drop in price at the major auction market in Thailand  
446 during the 1998-2000 La Niña (Sun 2007).

447

448 Building adaptive capacity is critical to alleviating the socio-economic impacts resulting from  
449 climate variability and change (Allison et al. 2009). While this study was largely based on  
450 economic analyses, the potential social impacts are pervasive given that a large proportion of  
451 purse seine vessel and IOT expenditures are directed at local employment and companies:  
452 recent analyses of direct, indirect and induced employment indicate that 8,400 persons are  
453 dependent on the tuna industry and related activities (Liam Campling, personal  
454 communication), constituting approximately 10% of Seychelles' population. Moreover,  
455 reductions in government revenues resulting from climate variability and change would  
456 undermine social policy interventions (e.g. health, education and housing). The coral reef  
457 fisheries, important for food security as well as employment, are also threatened by climate  
458 change (Graham et al. 2007), and tourism, the second pillar of the economy, is threatened by  
459 coastal erosion and degraded reef sites (Payet 2005). While Seychelles has a relatively high  
460 adaptive capacity to cope with climate change, compared to other countries in the region  
461 (McClanahan et al. 2008), the reliance on the marine environment to support the two main  
462 pillars of the economy warrants a greater emphasis on strengthening adaptive capacity and  
463 incorporating climate change in national policy and management interventions.

464

## 465 **5. Acknowledgements**

466 This study was funded by a GEF/UNDP project 'Enabling activities for the preparation of  
467 Seychelles' Second National Communication to the UNFCCC' and supported by Seychelles  
468 Fishing Authority. We thank the UNDP Project Coordination Unit and the Seychelles  
469 National Climate Change Committee for their support and encouragement during the study. L.

470 Campling and J. Beddington provided important advice for the study. We are also grateful for  
471 the valuable contribution of data and information by numerous stakeholders and institutions in  
472 Seychelles, and to Seychelles Fishing Authority for maintaining such excellent data collection  
473 systems and databases since the development of the tuna industry.
