The technique of relaxed power series expansion provides an efficient way to solve equations of the form 
\(F = \Phi(F),\) where the unknown \(F\) is a vector of power series, and where the solution can be obtained as the limit of the sequence \(0, \Phi(0), \Phi(\Phi(0)), \ldots.\)

With respect to other techniques, such as Newton’s method, two major advantages are its generality and the fact that it takes advantage of possible sparseness of \(\Phi\).

In this paper, we extend the relaxed expansion mechanism to more general implicit equations of the form \(\Phi(F) = 0.\)

1. Introduction

Let \(K\) be an effective field of constants of characteristic zero. Let \(F = (F^1, \ldots, F^r)\) be a column vector of \(r\) indeterminate series in \(K[[z]].\) We may also consider \(F\) as a power series \(F_0 + F_1 z + \cdots \in K^r[[z]].\) Let \(\Phi(F) = (\Phi(F)^1, \ldots, \Phi(F)^r)\) be a column vector of expressions built up from \(F, z\) and constants in \(K\) using ring operations, differentiation and integration (with constant term zero). Finally, let \(C_0, \ldots, C_{k-1} \in K^r\) be a finite number of initial conditions. Assume that the system

\[
\begin{cases}
\Phi(F) = 0 \\
F_0 = C_0 \\
\vdots \\
F_{k-1} = C_{k-1}
\end{cases}
\]

admits a unique solution \(f \in K[[z]]^r.\) In this paper, we are interested in the efficient computation of this solution up to a given order \(n.\)

In the most favourable case, the equation \(\Phi(F) = 0\) is of the form

\[
F - \Psi(F) = 0,
\]

where the coefficient \(\Psi(F)_n\) of \(z^n\) in \(\Psi(F)\) only depends on earlier coefficients \(F_0, \ldots, F_{n-1}\) of \(F,\) for each \(n \in \mathbb{N}.\) In that case,

\[
F_n = \Psi(F)_n
\]
actually provides us with a recurrence relation for the computation of the solution. Using the technique of relaxed power series expansions [vdH02a, vdH07], which will briefly be recalled in section 2, it is then possible to compute the expansion 
\[ F_n = F_0 + \cdots + F_{n-1} z^{n-1} \]
up till order \( n \) in time
\[ T(n) = s R(n) + O(t n), \]
where \( s \) is the number of multiplications occurring in \( \Psi \), where \( t \) is the total size of \( \Psi \) as an expression, and \( R(n) \) denotes the complexity of relaxed multiplication of two power series up till order \( n \). Here we assume that \( \Psi \) is represented by a directed acyclic graph, with possible common subexpressions. For large \( n \), we have \( R(n) = O(M(n) \log n) \), where \( M(n) = O(n \log n \log \log n) \) denotes the complexity [CT65, SS71, CK91] of multiplying two polynomials of degrees \( < n \). If \( K \) admits sufficiently many \( 2^p \)-th roots of unity, then we even have \( R(n) = O(M(n) e^{\sqrt{2 \log 2 \log \log n}}) \) and \( M(n) = O(n \log n) \). For moderate \( n \), when polynomial multiplication is done naively or using Karatsuba’s method, relaxed multiplication is as efficient as the truncated multiplication of polynomials at order \( n \).

One particularly important example of an equation of the above type is the integration of a dynamical system
\[ F = F_0 + \int \Psi(F), \]
where \( \Psi \) is algebraic (i.e. does not involve differentiation or integration). In that case, given the solution \( f \) up till order \( n \), we may consider the linearized system
\[ E' = \Psi(f) + J_\Psi(f) E + O(z^{2n}) \]
up till order \( 2n \), where \( J_\Psi(f) \) stands for the Jacobian matrix associated to \( \Psi \) at \( f \). If we also have a fundamental system of solutions of \( E' = J_\Psi(f) E \) up till order \( n \), then one step of Newton’s method allows us to find the solution of (4) and a new fundamental system of solutions of the linearized equation up till order \( 2n \) [BK78, BCO+06]. A careful analysis shows that this leads to an algorithm of time complexity
\[ T(n) = M(n) (2 s r + 2 s + 13/6 r^2 + 4/3 r + o(1)) + O(t r n). \]
In [vdH06], this bound has been further improved to
\[ T(n) = M(n) (2 s + 4/3 r + o(1)) + O(t n), \]
under the assumptions that \( K \) admits sufficiently many \( 2^p \)-th roots of unity and that \( r = O(\log n) \).

Although the complexity (5) is asymptotically better than (3) for very large \( n \), the relaxed approach often turns out to be more efficient in practice. Indeed, Newton’s method both suffers from a larger constant factor and the fact that we profit less from the potential sparsity of the system. Moreover, as long as multiplications are done in the naive or Karatsuba model, the relaxed approach is optimal in the sense that the computation of the solution takes roughly the same time as its verification. Another advantage of the relaxed approach is that it generalizes to more general functional equations and partial differential equations.

Let us now return to our original implicit system (1). A first approach for its resolution is to keep differentiating the system with respect to \( F \) until it becomes equivalent to a system of the form (2). For instance, if \( \Phi \) is algebraic, then differentiation of (1) yields
\[ J_\Phi(F) F'' + \frac{\partial \Phi}{\partial z}(F) = 0. \]
Consequently, if $J_\Phi(f)_0$ is invertible, then
\[
F = F_0 - \int J_\Phi(F)^{-1} \frac{\partial \Phi}{\partial z}(F)
\]
provides us with an equivalent system which can be solved by one of the previous methods. Unfortunately, this method requires the computation of the Jacobian, so we do not longer exploit the potential sparsity of the original system.

If $\Phi$ is a system of differentially algebraic equations, then we may also seek to apply Newton’s method. For non degenerate systems and assuming that we have computed the solution $f$ and a fundamental system of solutions for the linearized equation up till order $n$, one step of Newton’s method yields an extension of the solutions up till order $2n - i$, for a fixed constant $i \in \mathbb{N}$. From an asymptotic point of view, this means that the complexities (5) and (6) remain valid.

It is natural to ask for a relaxed algorithm for the resolution of (1), with a similar complexity as (3). We will restrict our attention to so-called “quasi-linear equations”, for which the linearized system is “non degenerate”. This concept will be introduced formally in section 3 and studied in more detail in section 6. In section 4, we present the main algorithm of this paper for the relaxed resolution of (1).

The idea behind the algorithm is simple: considering not yet computed coefficients of $F$ as formal unknowns, we solve the system of equations $\Phi(F)_0 = \cdots = \Phi(F)_n = 0$ for increasing values of $n$. In particular, the coefficients of the power series involved in the resolution process are no longer in $\mathbb{K}$, but rather polynomials in $F_0, F_1, \ldots$. For each subexpression $\Psi(F)$ of $\Phi(F)$ and modulo adequate substitution of known coefficients $F_n$ by their values $f_n$, it turns out that there exist constants $s \in \mathbb{Z}$ and $i \in \mathbb{N}$, such that $\Psi(F)_n$ is a constant plus a linear combination of $F_{n-s-i+1}, \ldots, F_{n-s}$, for large $n$. Moreover, each relaxed multiplication with symbolic coefficients can be reduced to a relaxed multiplication with constant coefficients and a finite number of scalar multiplications with symbolic coefficients. The main result is stated in theorem 5 and generalizes the previous complexity bound (3).

In section 6, we provide a more detailed study of the linearized system associated to (1). This will allow us to make the dependency of $\Psi(F)_n$ on $F_{n-s-i+1}, \ldots, F_{n-s}$ more explicit. On the one hand, given a quasi-linear system on input, this will enable us to provide a certificate that the system is indeed quasi-linear. On the other hand, the asymptotic complexity bounds can be further sharpened in lucky situations (see theorem 11). Finally, in the last section 7, we outline how to generalize our approach to more general functional equations and partial differential equations.

## 2. Relaxed power series

Throughout this article, $\mathbb{K}$ will denote an effective field of characteristic zero. This means that elements in $\mathbb{K}$ can be encoded by data structures on a computer and that we have algorithms for performing the field operations in $\mathbb{K}$.

Let us briefly recall the technique of relaxed power series computations, which is explained in more detail in [vdH02a]. In this computational model, a power series $f \in \mathbb{K}[[z]]$ is regarded as a stream of coefficients $f_0, f_1, \ldots$. When performing an operation $g = \Phi(f_1, \ldots, f_k)$ on power series it is required that the coefficient $g_n$ of the result is output as soon as sufficiently many coefficients of the inputs are known, so that the computation of $g_n$ does not depend on the further coefficients. For instance, in the case of a multiplication $h = fg$, we require that $h_n$ is output as soon as $f_0, \ldots, f_n$ and $g_0, \ldots, g_n$ are known. In particular, we may use the naive formula $h_n = \sum_{i=0}^{n} f_i g_{n-i}$ for the computation of $h_n$. 

\[ h_n = \sum_{i=0}^{n} f_i g_{n-i} \]
The additional constraint on the time when coefficients should be output admits the important advantage that the inputs may depend on the output, provided that we add a small delay. For instance, the exponential $g = \exp f$ of a power series $f \in \mathbb{K}[[z]]$ may be computed in a relaxed way using the formula

$$g = \int f' \, g.$$ 

Indeed, when using the naive formula for products, the coefficient $g_n$ is given by

$$g_n = \frac{1}{n} (f_1 g_{n-1} + 2 f_2 g_{n-2} + \cdots + f_n g_0),$$

and the right-hand side only depends on the previously computed coefficients $g_0, \ldots, g_{n-1}$.

The main drawback of the relaxed approach is that we cannot directly use fast algorithms on polynomials for computations with power series. For instance, assuming that $\mathbb{K}$ has sufficiently many $2^p$-th roots of unity and that field operations in $\mathbb{K}$ can be done in time $O(1)$, two polynomials of degrees $< n$ can be multiplied in time $M(n) = O(n \log n)$, using FFT multiplication [CT65]. Given the truncations $f_n = f_0 + \cdots + f_{n-1} z^{n-1}$ and $g_n = g_0 + \cdots + g_{n-1} z^{n-1}$ at order $n$ of power series $f, g \in \mathbb{K}[[z]]$, we may thus compute the truncated product $(f g)_n$ in time $M(n)$ as well. This is much faster than the naive $O(n^2)$ relaxed multiplication algorithm for the computation of $(f g)_n$. However, the formula for $(f g)_0$ when using FFT multiplication depends on all input coefficients $f_0, \ldots, f_{n-1}$ and $g_0, \ldots, g_{n-1}$, so the fast algorithm is not relaxed. Fortunately, efficient relaxed multiplication algorithms do exist:

**Theorem 1.** [vdH97, vdH02a] Let $M(n)$ be the time complexity for the multiplication of polynomials of degrees $< n$ in $\mathbb{K}[z]$. Then there exists a relaxed multiplication algorithm for series in $\mathbb{K}[[z]]$ of time complexity $R(n) = O(M(n) \log n)$.

**Theorem 2.** [vdH07] If $\mathbb{K}$ admits a primitive $2^p$-th root of unity for all $p$, then there exists a relaxed multiplication algorithm of time complexity $R(n) = O(n \log n e^{2\sqrt{\log 2\log \log n}})$. In practice, the existence of a $2^{p+1}$-th root of unity with $2^p \gg n$ suffices for multiplication up to order $n$.

An efficient C++ implementation of relaxed power series is available in the Mathemagix system [vdH+02b]. Leaving low-level pointer and memory management details apart, we will outline how the implementation works, using an informal pseudo-language. Relaxed power series in $\mathbb{K}[[z]]$ are implemented as an abstract base class $\text{Series}_\mathbb{K}$ which contains the already computed coefficients and a protected virtual method $\text{next}$ for computing the next coefficient. For instance, the naive product of $f, g$: $\text{Series}_\mathbb{K}$ can be implemented using the following concrete derived class $\text{ProductSeries}_\mathbb{K}$:

**Class** $\text{ProductSeries}_\mathbb{K} \supseteq \text{Series}_\mathbb{K}$

**Fields** $f, g: \text{Series}_\mathbb{K}$

**Constructor** $\text{product} (\tilde{f}: \text{Series}_\mathbb{K}, \tilde{g}: \text{Series}_\mathbb{K})$

$f := \tilde{f}, g := \tilde{g}$

**Method** $\text{next} (n: \mathbb{N})$

Return $\sum_{i=0}^n \text{coefficient} (f, i) \text{coefficient} (g, n - i)$

Let us briefly explain this code. In addition to the vector with the already computed coefficients (which is derived from $\text{Series}_\mathbb{K}$), the class $\text{ProductSeries}_\mathbb{K}$ contains two data fields for the multiplicands $f$ and $g$. The constructor $\text{product} (f, g)$ returns the product of two series $f, g: \text{Series}_\mathbb{K}$ and the method $\text{next}$ computes $(f g)_n$ using the naive relaxed method. The method $\text{next}$ does not take care of remembering previously computed coefficients and does not make sure that coefficients are computed in order. Therefore, a different public function $\text{coefficient}$ is used for the computation of the coefficients $f_i$ and $g_i$: 
Function coefficient \((f: \text{Series}_{\mathbb{K}}, n: \mathbb{N})\)

Let \(f_0, \ldots, f_{\#f}\) denote the already computed coefficients of \(f\)

If \(n > \#f\) then for \(i = \#f + 1, \ldots, n\) do \(f_i := f_{\text{next}(i)}\)

Return \(f_n\)

In the case of implicitly defined power series \(f\), the method \(\text{next}\) involves the series \(f = 0\) itself. For instance, exponentiation \(f := \exp g\) can be implemented as follows:

Class \(\text{ExpSeries}_{\mathbb{K}} \trianglerighteq \text{Series}_{\mathbb{K}}\)

Fields \(f, g: \text{Series}_{\mathbb{K}}\)

Constructor \text{product} \((\tilde{g}: \text{Series}_{\mathbb{K}})\)

\(g := \tilde{g}, f := \text{integrate (product (derive (g), this))}\)

Method \(\text{next} (n: \mathbb{N})\)

If \(n = 0\) then return 1

Else return coefficient \((f, n)\)

Example 3. Let us expand the exponential of \(g = z + z^2 + z^3 + \ldots\) using the above algorithms. Besides \(f\) and \(g\), three auxiliary series \(\varphi = g', \psi = \varphi f\) and \(\chi = \int \psi\) are created. Now the computation of \(f_4\) gives rise to the following sequence of assignments:

\[
\begin{array}{lcl}
\phi_0 & := & 1 \\
\phi_0 & := & g_0 = 1 \\
\psi_0 & := & \varphi_0 f_0 \\
\chi_0 & := & 0 \\
f_1 & := & \chi_1 := \psi_0 = 1 \\
\varphi_1 & := & 2 g_1 = 2 \\
\psi_1 & := & \varphi_0 f_1 + \varphi_1 f_0 \\
\chi_1 & := & 1 \\
f_2 & := & \chi_2 := \frac{\psi_1}{2} = \frac{3}{2} \\
\varphi_2 & := & 3 g_2 = 3 \\
\psi_2 & := & \varphi_0 f_2 + \varphi_1 f_1 + \varphi_2 f_0 \\
\chi_2 & := & 1 \\
f_3 & := & \chi_3 := \frac{\psi_2}{3} = \frac{13}{6} \\
\varphi_3 & := & 4 g_3 = 4 \\
\psi_3 & := & \varphi_0 f_3 + \varphi_1 f_2 + \varphi_2 f_1 + \varphi_3 f_0 = \frac{73}{6} \\
\chi_3 & := & 1 \\
f_4 & := & \chi_4 := \frac{\psi_3}{4} = \frac{73}{24} \\
\end{array}
\]

3. Implicit power series equations

Let \(F = (F^{[1]}, \ldots, F^{[r]})\) be a column vector of \(r\) indeterminate series in \(\mathbb{K}[[z]]\). Alternatively, \(F\) may be considered as a series with formal coefficients

\[
F = F_0 + F_1 z + \ldots,
\]

\[
F_n = (F_n^{[1]}, \ldots, F_n^{[r]})
\]

We will denote by \(\mathcal{E}\) the set of expressions built up from \(F, z\) and constants in \(\mathbb{K}\) using ring operations, differentiation and integration (with \((\int f)_0 = 0\) for all \(f \in \mathbb{K}[[z]]\)). Setting

\[
\mathbb{P} = \mathbb{K}[F_0, F_1, \ldots]
\]

\[
= \mathbb{K}[F_0^{[1]}, \ldots, F_0^{[r]}, F_1^{[1]}, \ldots, F_1^{[r]}, \ldots],
\]

any expression in \(\mathcal{E}\) may then be regarded as an element of \(\mathbb{P}[[z]]\).

For each \(\Phi \in \mathcal{E}\), we define \(v_\Phi \in \mathbb{Z} \cup \{\infty\}\) using the following rules:

\[
\begin{align*}
\Phi \in \mathbb{K}[[z]] & \implies v_\Phi = \text{val}_z \Phi \\
\Phi \in \{F^{[1]}, \ldots, F^{[r]}\} & \implies v_\Phi = 0 \\
\Phi \in \{\Psi + \Omega, \Psi - \Omega\} & \implies v_\Phi = \min \{v_\Psi, v_\Omega\} \\
\Phi = \Psi \Omega & \implies v_\Phi = v_\Psi + v_\Omega \\
\Phi = \Psi' & \implies v_\Phi = v_\Psi - 1 \\
\Phi = \int \Psi & \implies v_\Phi = v_\Psi + 1.
\end{align*}
\]
By induction, we have
\[ \text{val}_z \Phi \geq v_\Phi, \]
\[ \Phi_n \in \mathbb{K}[F_0, \ldots, F_{n-v_\Phi}], \]
for all \( \Phi \in \mathbb{E} \) and \( n \in \mathbb{N} \).

Let \( \Phi = (\Phi^{[1]}, \ldots, \Phi^{[r]}) \) be a column vector of \( r \) expressions in \( \mathbb{E} \). We will assume that \( \Phi \) depends on each of the indeterminates \( F^{[1]}, \ldots, F^{[r]} \). Given \( C_0, \ldots, C_{k-1} \in \mathbb{K}^r \), consider the implicit system with initial conditions
\[
\begin{cases}
\Phi = 0 \\
F_0 = C_0 \\
\vdots \\
F_{k-1} = C_{k-1}
\end{cases}
\]
(7)

For any \( n \geq k \), this system implies the following system \( \Sigma_n \) of equations in \( \mathbb{K}[F_0, \ldots, F_n] \):
\[
\Sigma_n = \begin{cases}
\Phi^{[1]}_{n-v_{\Phi^{[1]}}} = 0 \\
\vdots \\
\Phi^{[r]}_{n-v_{\Phi^{[r]}}} = 0
\end{cases}
\]
(8)

The system (7) is equivalent to the systems \( \Sigma_0, \Sigma_1, \ldots \) together with the initial conditions \( F_0 = C_0, \ldots, F_{k-1} = C_{k-1} \).

In what follows, we will assume that (7) admits a unique solution \( f \in \mathbb{K}[[z]]^r \). Given \( \Psi \in \mathbb{P}[[z]] \) and \( i \in \mathbb{N} \), we will denote by \( \sigma_i(\Psi) \) the series in \( \mathbb{P}[[z]] \) such that \( \sigma_i(\Psi)_n \) is the result of the substitution of \( F_j \) by \( f_j \) in \( \Psi_n \), for all \( n \in \mathbb{N} \) and \( j \leq n + v_\Phi - i \). If, for all \( i \in \mathbb{N} \), there exists an \( N_i \in \mathbb{N} \) such that \( \sigma_i(\Phi^{[j]}_{n-v_{\Phi^{[j]}}} \) is linear in \( F_{n-i+1}, \ldots, F_n \) for all \( n \geq N_i \) and \( j = 1, \ldots, r \), then we say that (7) is ultimately linear. In that case, \( \sigma_i(\Sigma_n) \) becomes a linear system of equations in \( F_{n-i+1}, \ldots, F_n \). More generally, the combined system
\[
\Sigma_{n,i} = \begin{cases}
\sigma_1(\Sigma_n) \\
\sigma_2(\Sigma_{n+1}) \\
\vdots \\
\sigma_i(\Sigma_{n+i-1})
\end{cases}
\]
(9)
is a linear system of equations in \( F_n, \ldots, F_{n+i-1} \) for all sufficiently large \( n \). If \( \Sigma_{n,i} \) is linear and \( F_n \) can be eliminated from \( \Sigma_{n,i} \) for all sufficiently large \( n \), then we say that (7) is quasi-linear. The minimal \( i \) for which \( F_n \) can be eliminated from \( \Sigma_{n,i} \) for all sufficiently large \( n \), \( F_n \) will then be called the index of (7). The minimal \( m \) such that \( F_n \) can be eliminated from \( \Sigma_{n,i} \) for all \( n \geq m \) will be called the offset.

**Example 4.** Let \( \Phi \in \mathbb{K}[z, F]^r \), \( k = 1 \) and assume that
\[
J = \begin{pmatrix}
\frac{\partial \Phi^{[1]}}{\partial F^{[1]}}_0 & \cdots & \frac{\partial \Phi^{[1]}}{\partial F^{[r]}}_0 \\
\vdots & \ddots & \vdots \\
\frac{\partial \Phi^{[r]}}{\partial F^{[1]}}_0 & \cdots & \frac{\partial \Phi^{[r]}}{\partial F^{[r]}}_0
\end{pmatrix}
\]
is invertible. Then for all \( n > 0 \), we have
\[
\Phi_n = J F_n + R_n,
\]
with \( R_n \in \mathbb{K}[F_0, \ldots, F_{n-1}] \). Hence, \( f_n \) can be computed from the previous coefficients using
\[
f_n = -J^{-1} R_n(f_0, \ldots, f_{n-1}).
The system $\sigma_1(\Sigma_n)$ consists of the equation

$$J F_n + R_n(f_0, \ldots, f_{n-1}) = 0,$$

from which $F_n$ can be eliminated. We conclude that (7) is quasi-linear, of index 1.

4. Relaxed resolution of implicit equations

Consider a quasi-linear system (7) of index $i$ with unique solution $f \in \mathbb{K}[[z]]^r$. We want to solve the system in a relaxed way, by computing the systems $\Sigma_{n,i}$ for increasing values $n = k, k + 1, \ldots$ and eliminating $F_n$ from $\Sigma_{n,i}$ using linear algebra. For each subexpression $\Psi$ of $\Phi$, we need to evaluate $\Psi = \sigma_i(\Psi) \in \mathbb{P}[[z]]$ in a relaxed way. The main challenge is to take advantage of the fact that $\sigma_i(\Psi)_n$ is really a constant plus a linear combination of $F_{n-v_0-i+1}, \ldots, F_{n-v_0}$ and to integrate the necessary substitutions of newly computed coefficients by their values into the relaxed resolution process.

Denote the inner product of vectors by $\cdot$. For each $v \in \mathbb{Z}$ and $i \in \mathbb{N}$, let $\mathbb{P}[[z]]_{v,i}$ be the subset of $\mathbb{P}[[z]]$ such that

$$\Psi_{n+v} = \Psi_{n+v} + \Psi^{(i-1)}_{n+v} \cdot F_{n-i+1} + \cdots + \Psi^{(0)}_{n+v} \cdot F_n,$$

(10)

for all $n \geq -v$. Then $\mathbb{P}_{v,i}$ is a $\mathbb{K}$-vector space and

$$\Psi \in \mathbb{P}[[z]]_{v,i} \implies \mathbb{P}[[z]]_{v+1,i} \subseteq \mathbb{P}[[z]]_{v,i},$$

$$\Psi \in \mathbb{P}[[z]]_{v,i} \implies \Psi' \in \mathbb{P}[[z]]_{v-1,i},$$

$$\Psi \in \mathbb{P}[[z]]_{v,i} \implies \sum \Psi \in \mathbb{P}[[z]]_{v+1,i}.$$ Given $\Psi \in \mathbb{P}_{v,i}$ with $i > 0$, we define the one-step substitution $\tau(\Psi) \in \mathbb{P}[[z]]_{v+1,i-1}$ by

$$\tau(\Psi)_{n+v} = \Psi_{n+v} + \Psi^{(i-1)}_{n+v} \cdot F_{n-i+1} + \Psi^{(i-2)}_{n+v} \cdot F_{n-i+2} + \cdots + \Psi^{(0)}_{n+v} \cdot F_n.$$  

In particular, $\tau(\sigma_i(\Psi)) = \sigma_{i-1}(\Psi)$ and the the iterate $\tau^i(\Psi)$ coincides with the full substitution $\sigma_0(\Psi) \in \mathbb{K}[[z]]$ of $F$ by $f$ in $\Psi$.

It remains to be shown how to multiply two series $\Psi \in \mathbb{P}[[z]]_{v,i}$ and $\Omega \in \mathbb{P}[[z]]_{w,i}$ in a suitable way, without introducing quadratic terms in $F$. Given $t \in \mathbb{N}$, it will be convenient to introduce shift operators

$$\Psi_{\leq t} = \Psi z^t,$$

$$\Psi_{> t} = \Psi + \Psi_{t+1} z^1 + \cdots.$$ We recursively define the substitution product $\Psi \ast_i \Omega \in \mathbb{P}[[z]]_{v+w,i}$ of $\Psi$ and $\Omega$ by

$$\Psi \ast_0 \Omega = \Psi \Omega,$$

$$\Psi \ast_i \Omega = \sigma_0(\Psi_0) \Omega_0 + \sigma_0(\Psi_0) \Omega_{>1} + \Psi_{>1} \sigma_0(\Omega_0) \leq 1 + \tau(\Psi_{>1}) \ast_{i-1} \tau(\Omega_{>1}) \leq 2$$

(11)

using the fact that $\tau(\Psi_{>1}), \tau(\Omega_{>1}) \in \mathbb{P}[[z]]_{v+w,i-1}$. Unrolling (11), we have

$$\Psi \ast_i \Omega = \sum_{j \leq i} [\sigma_0(\Psi_j) \sigma_0(\Omega_j)] \leq 2j + \sigma_0(\Psi_j) \tau^j(\Omega_{>j+1}) + \tau^j(\Psi_{>j+1}) \sigma_0(\Omega_j) \leq 2j+1 + \tau^j(\Psi_{>j}) \tau^i(\Omega_{>i}) \leq 2i.$$  

(12)

The substitution product satisfies the important property

$$\sigma_i(\Psi) \ast_i \sigma_i(\Omega) = \sigma_i(\Psi \Omega).$$
Moreover, it respects the constraint that $\sigma_i(\Psi \Omega)_n - v_q \Omega$ can be computed as soon as $\sigma_j(\Psi)_j - v_q \Psi$ and $\sigma_j(\Omega)_j - v_q \Omega$ are known for $j \leq n$. Recall that the computation of $\sigma_i(\Psi)_n - v_q \Psi$ requires the previous computation of $f_0, ..., f_{n-i}$.

From the implementation point of view, we proceed as follows. We introduce a new data type $\mathbb{D}$, whose instances are of the form

\[
\begin{aligned}
c &= (f_c, n_c, i_c, c^*, c(0), ..., c(i_c-1)) \\
n_c, i_c &\in \mathbb{N} \\
c^* &\in \mathbb{K} \\
c(j) &\in \mathbb{K}^r (j = 0, ..., i - 1),
\end{aligned}
\]

where $f_c = f$ stands for the relaxed power series solution of (7). Such an instance $c$ represents

\[
c \equiv c^* + c(i_c-1) \cdot f(n_c - i_c + 1) + ... + c(0) \cdot f(n_c).
\]

Denoting by $\mathbb{D}_i$ the subtype of instances $c$ in $\mathbb{D}$ with $i_c \leq i$, we may thus view series $\Psi \in \mathbb{P}[z]_{i+1}$, as elements of $\mathbb{D}_i[z]$. We have a natural inclusion $\mathbb{K} \rightarrow \mathbb{D}; a \mapsto (0,0,0,a)$, where we notice that $f_c$ does not matter if $i_c = 0$, and a constructor $(f,n) \mapsto (f,n,1,0,1)$ for the unknown $F_n$. The $\mathbb{K}$-vector space operations on $\mathbb{D}$ are implemented in a straightforward way. The one-step substitution operator $\tau$ is implemented by

\[
\tau(c) = (f_c, n_c, i_c - 1, c^* + c(i_c-1) \cdot f(n_c - i_c + 1), c(0), ..., c(i_c-2))
\]

if $i_c > 0$ and $\tau(c) = c$ otherwise. On a fixed $\mathbb{D}_i$, this allows us to implement the substitution product $*_{i}$ using (11). Moreover, by casting $\tau^i(\Psi_{\gg i})$ and $\tau^i(\Omega_{\gg i})$ to relaxed series in $\text{Series}_{\mathbb{K}}$, we may compute the product $\tau^i(\Psi_{\gg i}) \tau^i(\Omega_{\gg i})$ using a fast relaxed product in $\text{Series}_{\mathbb{K}}$. We are now in a position to state our relaxed algorithm for solving (7).

**Class ImplicitSeries**

**Fields** $\varphi : \text{Series}_{\mathbb{D}_i}$, $\Sigma : \text{Set}_{\mathbb{D}_i}$, $p : \mathbb{N}$

**Constructor** implicit $(\Phi : \mathbb{E}^r, C_0: \mathbb{K}^r, ..., C_{k-1}: \mathbb{K}^r)$

\[
F := \text{UnknownSeries}_{\mathbb{D}_i}(\text{this}, C_0, ..., C_{k-1})
\]

$\varphi := \Phi[F]$  

$\Sigma := \emptyset$ and $p := k$

**Method** next $(n : \mathbb{N})$

**While true**

**If** $p > n + i$ **then** raise an error

$\Sigma := \Sigma \cup \{ \varphi_{p - v_q j} ; j \in \{ 1, ..., r \}, p \geq v_q j \}$ and $p := p + 1$

Triangulize $\Sigma$ by eliminating $F_l$ with large $l$ first

$\Sigma := \Sigma \setminus \{ 0 \}$

**If** $\Sigma \cap K \neq \emptyset$ **then** raise an error

**If** $\Sigma = \Sigma_1 \cup \Sigma_2$ where card $\Sigma_2 = r$ and $\Sigma_2$ only involves $F_{n}[1], ..., F_{n}[r]$ **then**

Let $c \in \mathbb{K}^r$ be the unique solution to $\Sigma_2$ as a system in $F_n$

Let $\Sigma := \Sigma_1$ and substitute $c$ for $F_n$ in $\Sigma$

**Return** $c$

The following subalgorithm is used for the symbolic construction of the unknown series $F = C_0 + ... + C_{k-1} z^{k-1} + F_k z^k + F_{k+1} z^{k+1} + ...$:

**Class UnknownSeries**

**Fields** $f : \text{Series}_{\mathbb{K}^r}$, $C_0: \mathbb{K}^r, ..., C_{k-1}: \mathbb{K}^r$

**Constructor** implicit $(f : \text{Series}_{\mathbb{K}^r}, C_0: \mathbb{K}^r, ..., C_{k-1}: \mathbb{K}^r)$

$f := \tilde{f}$, $C_0 := \tilde{C}_0, ..., C_{k-1} := \tilde{C}_{k-1}$
Consider the system

\[
\begin{align*}
\Phi &= F - G + zFG = 0 \\
\Psi &= z (F' - G') + zFG = 0 \\
F_0 &= 1 \\
G_0 &= 1
\end{align*}
\]

It is not hard to find the unique explicit solution \((f, g) \in \mathbb{K}[[z]]^2\) of this system. Indeed,

\[z \Phi' - \Psi = z^2 (FG)',\]

whence \(fg \in \mathbb{K}\). Since \(f_0 = g_0 = 1\), it follows that \(fg = 1\). Plugging this into the first equation \(f - g + zg = 0\), we get \(f^2 - 1 + z = 0\), whence \(f = (1 - z)^{1/2}\) and \(g = (1 - z)^{-1/2}\).
During the computations below, we will see that the system is quasi-linear of index 2. Denoting the relaxed solution by \((f, g) \in K[[z]]^2\), we will have to compute \(f, g\) and the series \(F, G, F G \in D_2[[z]]\).

**Initialization.** At the very start, we have \(f_0 = g_0 = \hat{F}_0 = \hat{G}_0 = 1\).

**Step 1.** The evaluations of \(\Phi_1\) and \(\Psi_1\) yield
\[
\Phi_1 = \hat{F}_1 - \hat{G}_1 + f_0 g_0 = 1 + F_1 - G_1 \\
\Psi_1 = \hat{F}_1 - \hat{G}_1 + f_0 g_0 = 1 + F_1 - G_1 \\
\Sigma := \{F_1 - G_1 + 1\}
\]
These relations do not yet enable us to determine \(f_1\) and \(g_1\).

**Step 2.** The evaluations of \(\Phi_2\) and \(\Psi_2\) yield
\[
\Phi_2 = \hat{F}_2 - \hat{G}_2 + \hat{F}_1 g_0 + f_0 \hat{G}_1 = F_1 + G_1 + F_2 - G_2 \\
\Psi_2 = \hat{F}_2 - 2 \hat{G}_2 + \hat{F}_1 g_0 + f_0 \hat{G}_1 = F_1 + G_1 + 2 F_2 - 2 G_2 \\
\Sigma := \{F_2 - G_2 + F_1 + G_1, 2 F_2 - 2 G_2 + F_1 + G_1, F_1 - G_1 + 1\}
\]
After triangularization, we get
\[
\Sigma := \{F_2 - G_2 + F_1 + G_1, F_1 + G_1, -2 G_1 + 1\}.
\]
The two last equations imply \(f_1 = -\frac{1}{2}\) and \(g_1 = \frac{1}{2}\).

**Step 3.** Evaluations of \(\Phi_3\) and \(\Psi_3\) and triangularization of \(\Sigma\) yield
\[
\Phi_3 = \hat{F}_3 - \hat{G}_3 + \hat{F}_2 g_0 + f_1 g_1 + f_0 \hat{G}_2 = -\frac{1}{4} + F_2 + G_2 + F_3 - G_3 \\
\Psi_3 = -\frac{1}{4} + F_2 + G_2 + 3 F_3 - 3 G_3 \\
\Sigma := \{F_3 - G_3 + F_2 + G_2 - \frac{1}{4}, 2 F_2 + 2 G_2 - \frac{1}{2}, 4 G_2 - \frac{1}{2}\}
\]
From the equations \(3 \Phi_3 - \Psi_3 = 0\) and \(\Psi_2 - \Phi_2 = 0\), we get \(f_2 = g_2 = \frac{1}{8}\).

**Further steps.** For \(n \geq 4\), the evaluations of \(\Phi_n\) and \(\Psi_n\) yield
\[
\Phi_n = F_n - G_n + F_{n-1} g_0 + (f_{n-2} g_1 + \cdots + f_1 g_{n-2}) + f_0 \hat{G}_{n-1} \\
= (f_{n-2} g_1 + \cdots + f_1 g_{n-2}) + F_{n-1} + G_{n-1} + F_n - G_n \\
\Psi_n = (f_{n-2} g_1 + \cdots + f_1 g_{n-2}) + F_{n-1} + G_{n-1} + n F_n - n G_n \\
\Sigma := \{F_n - G_n + F_{n-1} + G_{n-1} + f_{n-2} g_1 + \cdots + f_1 g_{n-2}, \\
(n-1) F_{n-1} + (n-1) G_{n-1} + (f_{n-2} g_1 + \cdots + f_1 g_{n-2}) \\
2 (n-1) G_{n-1} + f_{n-2} g_1 + \cdots + f_1 g_{n-2}\}.
\]
After triangularization, we thus get
\[
\Sigma := \{F_n - G_n + F_{n-1} + G_{n-1} + f_{n-2} g_1 + \cdots + f_1 g_{n-2}, \\
(n-1) F_{n-1} + (n-1) G_{n-1} + f_{n-2} g_1 + \cdots + f_1 g_{n-2} \\
2 (n-1) G_{n-1} + f_{n-2} g_1 + \cdots + f_1 g_{n-2}\}.
\]
Consequently, \(f_{n-1} = g_{n-1} = -\frac{1}{2(n-1)} (f_{n-2} g_1 + \cdots + f_1 g_{n-2})\).
6. Symbolic linearization

Assume that the system (7) is quasi-linear. Given a subexpression \( \Psi \) of \( \Phi \) an integer \( i \in \mathbb{N} \) and \( j \in \{1, \ldots, r\} \), we claim that the coefficient \([F^{[j]}_{n-\nu \Phi-\iota}]_1\)(\( \Psi \)) of \( F^{[j]}_{n-\nu \Phi-\iota} \) in \( \sigma_{1+i}(\Psi)_n \) (and which corresponds to \([\Psi^{(i)}_n]_j\) in (10)) is a rational function in \( n \), for sufficiently large \( n \). There are two ways to see this.

Let \( E^{\text{rat}} \) denote the set of expressions \( \Psi \), such that for all \( i \in \mathbb{N} \) there exist vectors of rational functions \( \Psi^{(0)}, \ldots, \Psi^{(i-1)} \in \mathbb{K}(N)^r \) and a sequence \( \Psi_n^i \) with

\[
\sigma_i(\Psi)_n = \Psi_n^i + \Psi^{(i-1)}_n \cdot F_{n-\nu \Phi-i+1} + \cdots + \Psi^{(0)}_n \cdot F_{n-\nu \Phi},
\]

for all sufficiently large \( n \). In other words,

\[
[\Psi^{(i)}(n)]_j = [F^{[j]}_{n-\nu \Phi-\iota}]_1 \sigma_{i+1}(\Psi)_n,
\]

for \( j = 1, \ldots, r \) and sufficiently large \( n \). We define \( \Psi^{(i)} = 0 \) if \( i < 0 \). We clearly have \( \mathbb{K}[z] \subseteq E^{\text{rat}} \) and \( F^{[1]}, \ldots, F^{[r]} \in E^{\text{rat}} \). Assume that \( \Psi, \Omega \in E^{\text{rat}} \). Then \( \Psi + \Omega, \Psi - \Omega, \Psi \cdot \Omega, \Psi^2 \cdot f \in E^{\text{rat}} \) and we may explicitly compute the corresponding rational functions using

\[
\begin{align*}
(\Psi + \Omega)^{[i]} &= \Psi^{[i+\nu \Phi + \Omega - \nu \Phi]} + \Omega^{[i+\nu \Phi + \Omega - \nu \Phi]}, \\
(\Psi - \Omega)^{[i]} &= \Psi^{[i+\nu \Phi + \Omega - \nu \Phi]} - \Omega^{[i+\nu \Phi + \Omega - \nu \Phi]}, \\
(\Psi \Omega)^{[i]}(n) &= \Psi \nu \Phi^{[i]}(n + \nu \Phi) + \cdots + \Psi \nu \Phi^{[i+1]}(n + \nu \Phi - i) + \\
&\quad \Psi^{[i]}(n + \nu \Omega) \Omega_{v_1} + \cdots + \Psi^{[0]}(n + \nu \Omega - i) \Omega_{v_1+i}, \\
(\Psi^2)^{[i]}(n) &= (n+1) \Psi^{[i]}(n + 1), \\
(f \cdot \Psi)^{[i]}(n) &= \frac{1}{n} \Psi^{[i]}(n - 1).
\end{align*}
\]

If \( \Psi \) is a polynomial, then we notice that \( [\Psi^{(i)}]_j \in \mathbb{K}^r \) for all \( i \) and \( j \). If \( \Psi \) is a differential polynomial of order \( q \), then \( [\Psi^{(i)}]_j \) is a polynomial in \( \mathbb{K}[N] \) of degree \( \leq q \). In general, the degrees of the numerator and denominator of \( [\Psi^{(i)}]_j \) are bounded by the maximal number of nested differentiations resp. integrations occurring in \( \Psi \).

An alternative way to determine the \( \Psi^{(i)} \) is to consider \( F = f - E \) as a perturbation of the solution and perform a Taylor series expansion

\[
\Psi(f + E) = \Psi(f) + (D \Psi)(f)(E) + \frac{1}{2} (D^2 \Psi)(f)(E, E) + \cdots.
\]

The coefficients \( \Psi^{(i)} \) can then be read off from the linear term using

\[
\Psi^{(i)}(n)^{[j]} = [F^{[j]}_{n-\nu \Phi-i}] (D \Psi)(f)(F - f) = [F^{[j]}_{n-\nu \Phi-i}] (D \Psi)(f)(F).
\]

For instance, consider the expression

\[
\Psi = \int f G' + z^2 F''
\]

\[
(D \Psi)(\begin{bmatrix} f \\ g \end{bmatrix}) = \int f G' + \int F g' + z^2 F''.
\]

Then we have

\[
\Psi^{(i)}(n) = \begin{pmatrix} 1 \\ \frac{i}{n} \sum_{i=1}^{n-1} f_i \end{pmatrix},
\]

\[
\Psi^{(i)}_n = \begin{pmatrix} F_{n-i} \left( \int f G' + \int F g' + z^2 F'' \right)_n \\ G_{n-i} \left( \int f G' + \int F g' + z^2 F'' \right)_n \end{pmatrix}.
\]
with $\delta_{0,i} = 1$ if $i = 0$ and $\delta_{0,i} = 0$ otherwise.

A first theoretical consequence of our ability to compute symbolic expressions for $\Psi^{(i)}$ is the following:

**Theorem 8.** There exists an algorithm which takes a quasi-linear system (7) on input and computes its index and its offset.

**Proof.** The system (9) can be rewritten as a matrix-vector equation

$$M_n X_n = Y_n. \quad (15)$$

Here $X_n \in \mathbb{K}^{ir}$ is a column vector with entries $F_n^{[1]} \ldots F_n^{[r]}$, $F_n^{[1]} \ldots F_n^{[r]}$ and $Y_n \in \mathbb{K}^{ir}$. The entries of the matrix $M_n \in \mathbb{K}^{ir \times ir}$ are coefficients of the form $(\Phi^{(j)}_{k,q})^{[j]}$. In particular, we can compute a matrix $M \in \mathbb{K}(N)^{ir \times ir}$ such that the matrix $M_n$ is given by the specialization $M(n)$ of $M$ at $N = n$ for sufficiently large $n$.

Let $T \in \mathbb{K}(N)^{ir \times ir}$ be the symbolic triangularization of $M$. For sufficiently large $n$, the triangularization $T_n$ of $M_n$ coincides with $T(n)$ for $n \geq n_0$. Now $F_n$ may be eliminated from the equation (15) if and only if the last $r$ non zero rows and the last $r$ columns of $T_n$ are an invertible triangular matrix. This is the case for all sufficiently large $n$ if and only if the last $r$ non zero rows and the last $r$ columns of $T$ are an invertible triangular matrix in $\mathbb{K}(N)^{ir \times ir}$. We compute the index of (7) as being the smallest $i$ for which this is the case.

As to the offset, we first observe that we may explicitly compute an $n_0 \in \mathbb{N}$ such that $M_n = M(n)$ and $T_n = T(n)$ for all $n \geq n_0$, since the values $n_0$ for which these equations do not hold are roots of a polynomial with coefficients in $\mathbb{K}$. Using the algorithm from section 4, we may compute the solution $f$ up to any given order $n$. We thus compute the offset as being the smallest $k \in \mathbb{N}$ such that $F_n$ can be eliminated from (15) for all $k \leq n < n_0$. □

**Example 9.** For the example from section 5, the equation (15) becomes

$$\begin{pmatrix}
1 & -1 & 1 & 1 \\
-1 & 1 & 1 & 1 \\
0 & 0 & 1 & -1 \\
0 & 0 & -1 & -n + 1
\end{pmatrix}
\begin{pmatrix}
F_n \\
G_n \\
F_n - 1 \\
G_n - 1
\end{pmatrix}
= 
\begin{pmatrix}
-(f_{n-2} g_1 + \cdots + f_1 g_{n-2}) \\
-(f_{n-2} g_1 + \cdots + f_1 g_{n-2}) \\
0 \\
0
\end{pmatrix}.$$

**Remark 10.** An interesting theoretical question is how to test whether a given system is quasi-linear. The proof technique of the theorem at least gives us a partial answer: if a system is quasi-linear, then we will be able to provide a certificate for this fact. Most systems encountered in practice are indeed quasi-linear, provided that we have sufficiently many initial conditions. In the contrary case, it is usually possible to find a simpler equivalent quasi-linear system. It would be nice to prove a general theorem in this direction.

A second consequence of our ability to compute symbolic expressions for $\Psi^{(i)}$ is that we can avoid the systematic computation of the coefficients $\Psi_n^{(i)}$ using arithmetic in $\mathbb{D}$: we rather compute $\Psi_n^{(i)}$ on demand, by evaluating $\Psi^{(i)}$ at $N = n$. The coefficients $\Psi_n^{(i)}$ are essentially needed at two places: for the computation of substitution products and for the computation of the system $\Sigma$. Let $q$ be the cost of an evaluation of $\Psi^{(i)}$: if $\Psi$ is a polynomial, then $q = 1$; if $\Psi$ is a differential polynomial, then $q$ is its order plus one; etc..

When computing $\Psi_n^{(i)}$ by evaluating $\Psi^{(i)}$ at $N = n$, the computation of one coefficient of a one-step substitution $\tau$ amounts to $r$ evaluations of rational functions of the form $(\Psi^{(i)})^{[j]}$. Consequently, every substitution product amounts to a cost $R(n) + O(i r q n)$ in the final complexity.
As to the computation of a coefficients $F_n$, we may compute $M_n$ as in (15) using $(i r)^2$ evaluations of cost $q$ and then solving a linear system of size $i r$. This gives rise to a cost $O((i r + q) (i r)^2 n)$ in the final complexity. Alternatively, as a side effect of the triangularization of $M$ with the notations from (15), we may compute a symbolic matrix $S \in \mathbb{K}(N)^{r \times i r}$ such that $F_n = S(n) Y_n$ for all sufficiently large $n$. If the system (7) is algebraic, then $S \in \mathbb{K}^{ir \times i r}$ actually has constant coefficients, so the complexity further reduces to $O(i r^2)$. In general, the evaluation of $S$ will be more expensive, so it is not clear whether this strategy pays off. Altogether, we have proved:

**Theorem 11.** Let (7) be an equation of index $i$ of total size $t$ and containing at most $s$ multiplications. Assume that the equations involve strictly less than $q$ nested derivations or integrations. Then $f_0, \ldots, f_{n-1}$ can be computed in time

$$T(n) = s R(n) + O((s q + i r q + i^2 r^2) i r n + t n).$$

If (7) is algebraic, then the complexity further drops down to

$$T(n) = s R(n) + O((s + r) i r n + t n).$$

**Remark 12.** The algorithm from this section has not been implemented yet. The new complexity bound constitutes an improvement mainly in the algebraic case. Since the manipulation of non constant coefficients in $\mathbb{D}$ gives rise to a small but non negligible amount of overhead for small and moderate $n$ (see remark 7), we indeed expect further gains in this case.

### 7. Generalizations

For simplicity, the presentation of this paper has been focused on ordinary differential equations. Nevertheless, the techniques admit generalizations in several directions. We will outline two such generalizations.

**Functional equations.** Let $G$ be a set of relaxed power series $g \in \mathbb{K}[[z]]$ with $g_0 = 0$ and replace $\mathcal{E}$ by the set of expressions built up from $F$, $z$ and constants in $\mathbb{K}$ using ring operations, differentiation, integration and right composition with series in $G$.

Assume first that $\text{val } g = 1$ for all $g \in G$. In a similar way as in section 6, there exists a symbolic expression of the form (13) for each $\Psi \in \mathcal{E}$, except that we now have

$$\Psi^{(i)} \in \mathbb{K}(N)[(g_1)^{Y_1}, \ldots, (g_l)^{Y_l}],$$

where $g_1, \ldots, g_l \in G$ are the functions which occur as postcomposers in $\Psi$. In particular, if $(g_1), \ldots, (g_l) \in \mathbb{R}$, then the $\Psi^{(i)}$ are contained in a Hardy field, and theorem 8 generalizes.

The above observation further generalizes to the case when $\text{val } g > 1$ for certain $g \in G$. In non degenerate cases, expressions $F^{(i)} \circ g$ with $\text{val } g > 1$ only occur as perturbations, and (16) still holds. In general, we also have to consider degenerate situations, such as the case when

$$\Psi^{(i)}(\alpha N + \beta) \in \mathbb{K}(N)[(g_1)^{Y_1}, \ldots, (g_l)^{Y_l}]$$

for a certain $\alpha > 1$ and all $\beta = 0, \ldots, \alpha - 1$.

One may even consider functional equations in which we also allow postcompositions with general expressions $g \in \mathcal{E}$ with $g_0 = 0$. Although the theory from section 6 becomes more and more intricate, the algorithm from section 4 generalizes in a straightforward way.
Partial differential equations. We may also consider power series in several variables $z_1, \ldots, z_d$. Given a multivariate power series $f \in \mathbb{K}[[z]] = \mathbb{K}[[z_1, \ldots, z_d]]$ and $n \in \mathbb{N}^d$, we denote by $f_n$ the coefficient of $z^n = z_1^{n_1} \cdots z_d^{n_d}$ in $f$, and let $P = \mathbb{K}[F_n; n \in \mathbb{N}^d]$. The expressions in $E$ are built up from $F$, $z_1, \ldots, z_d$ and constants in $\mathbb{K}$ using ring operations and partial differentiation or integration with respect to the $z_1, \ldots, z_d$. The number $v_\Phi$ now becomes a vector in $(\mathbb{Z} \cup \{\infty\})^d$.

The simplest, blockwise generalization proceeds as follows. Indices $i, j \in \mathbb{N}^d$ are compared using the product ordering $i \preceq j \Leftrightarrow i_1 \leq j_1 \wedge \cdots \wedge i_d \leq j_d$. Given $i \in \mathbb{N}^d$ and $\Phi \in E$, we let $\sigma_i(\Phi)$ be the series in $P[[z]]$ such that $\sigma_i(\Phi)_n$ is the result of the substitution of $F_j$ by $f_j$ in $\Phi_n$, for all $n \in \mathbb{N}^d$ and $j \preceq n + v_\Phi - i$. Given $v \in \mathbb{Z}^d$ and $i \in \mathbb{N}^d$, we let $P[[z]]_{v,i}$ be the subset of $\Phi \in P[[z]]$ such that

$$\Psi_{n+v} = \Psi_{n+v}^* + \sum_{0 \leq j \leq i-1} \Psi_{n+v}^{(j)} \cdot F_{n-j},$$

for each $l \in\{1, \ldots, d\}$, let $e_l \in \mathbb{N}^d$ be such that $(e_l)_l = 1$ and $(e_l)_j = 0$ for $j \neq l$. We define the one-step partial substitution $\tau(\Phi)_{n+v} = \Psi_{n+v}^* + \sum_{(i-1) \leq j \leq i-1} \Psi_{n+v}^{(j)} \cdot f_{n-j} + \sum_{0 \leq j \leq i-1 - e_l} \Psi_{n+v}^{(j)} \cdot F_{n-j}$.

The partial shifts $\Psi_{\leq i}$ and $\Psi_{\geq i}$ are defined similarly and we denote by $\Psi_{=0}$ the substitution of 0 for $z_i$ in $\Psi$. The substitution product is defined recursively. If $i = 0$, then we set $\Psi \cdot \Omega = \Psi \cdot \Omega$. Otherwise, we let $l \in \{1, \ldots, r\}$ be smallest such that $i_l$ is maximal and take

$$\Psi \cdot \Omega = \sigma_0(\Psi_{=0}) \cdot \sigma(\Omega_{\leq 0}) + [\sigma_0(\Psi_{=0}) \cdot \Omega_{\leq 1} + \Psi_{\geq 1}^* \cdot \sigma_0(\Omega_{\geq 1})]_{\leq 1} + [\tau(\Psi_{\geq 1}) \cdot \Omega_{\leq 1} \cdot \tau(\Omega_{\geq 1})]_{\leq 2}.$$ 

Using this substitution product, the algorithm from section 4 generalizes. The theory from section 6 can also be adapted. However, theorem 8 admits no simple analogue, due to the fact that there is no algorithm for determining the integer roots of a system of multivariate polynomials.

Several variants are possible depending on the application. For instance, it is sometimes possible to consider only the $\Psi_{n+v}^{(j)}$ up till a certain total degree $j_1 + \cdots + j_d \leq i$ in (17), instead of a block of coefficients. For some applications, it may also be interesting to store the $\Psi_{n+v}^{(j)}$ in a sparse vector.
