HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
ON THE EXISTENCE OF DISTINCT LENGTHS ZERO-SUM SUBSEQUENCES

by

Benjamin Girard

Abstract. — In this paper, we obtain a characterization of short normal sequences over a finite Abelian $p$-group, thus answering positively a conjecture of W. Gao for a variety of such groups. Our main result is deduced from a theorem of N. Alon, S. Friedland and G. Kalai, originally proved so as to study the existence of regular subgraphs in almost regular graphs. In the special case of elementary $p$-groups, Gao’s conjecture is solved using N. Alon’s Combinatorial Nullstellensatz. To end with, we show that, assuming every integer satisfies Property B, this conjecture holds in the case of finite Abelian groups of rank two.

1. Introduction

Let $P$ be the set of prime numbers and let $G$ be a finite Abelian group, written additively. By $\exp(G)$ we denote the exponent of $G$. If $G$ is cyclic of order $n$, it will be denoted by $C_n$. In the general case, we can decompose $G$ as a direct product of cyclic groups $C_{n_1} \oplus \cdots \oplus C_{n_r}$ where $1 < n_1 | \cdots | n_r \in \mathbb{N}$. For every $g$ in $G$, we denote by $\text{ord}(g)$ its order in $G$, and by $\langle g \rangle$ the subgroup it generates.

By a sequence over $G$ of length $\ell$, we mean a finite sequence of $\ell$ elements from $G$, where repetitions are allowed and the order of elements is disregarded. We use multiplicative notation for sequences. Let

$$S = g_1 \cdot \ldots \cdot g_\ell = \prod_{g \in G} g^{v_g(S)}$$

be a sequence over $G$, where, for all $g \in G$, $v_g(S) \in \mathbb{N}$ is called the multiplicity of $g$ in $S$. We call $\text{Supp}(S) = \{g \in G \mid v_g(S) > 0\}$ the support of $S$, and $\sigma(S) = \sum_{i=1}^\ell g_i = \sum_{g \in G} g v_g(S)$ the sum of $S$. In addition, we say that $s \in G$ is a subsum of $S$ when

$$s = \sum_{i \in I} g_i$$

for some $\emptyset \subsetneq I \subseteq \{1, \ldots, \ell\}$.

If 0 is not a subsum of $S$, we say that $S$ is a zero-sumfree sequence. If $\sigma(S) = 0$, then $S$ is said to be a zero-sum sequence. If moreover one has $\sigma(T) \neq 0$ for all proper subsequences $T \mid S$, then $S$ is called a minimal zero-sum sequence.

By $D(G)$ we denote the smallest integer $t \in \mathbb{N}^*$ such that every sequence $S$ over $G$ of length $|S| \geq t$ contains a non-empty zero-sum subsequence. The number $D(G)$ is called the

Davenport constant of the group $G$. Even though its definition is purely combinatorial, the invariant $D(G)$ found many applications in number theory (see for instance the book [13] which presents the various aspects of non-unique factorization theory, and [12] for a recent survey). Thus, many direct and inverse problems related to $D(G)$ have been studied during last decades, and even if numerous results were proved (see Chapter 5 in [13], and [8] for a survey), its exact value is known for very special types of groups only.

A sequence $S$ over a finite Abelian group $G$ is said to be dispersive if it contains two non-empty zero-sum subsequences $S_1$ and $S_2$ with distinct lengths, and non-dispersive otherwise, that is when all the non-empty zero-sum subsequences of $S$ have same length. One can readily notice, using the very definition of the Davenport constant, that every sequence $S$ over $G$ with $|S| \geq 2D(G)$ is dispersive, since $S$ has to contain at least two disjoint non-empty zero-sum subsequences. So, one can ask for the smallest integer $t \in \mathbb{N}^*$ such that every sequence $S$ over $G$ with $|S| \geq t$ is dispersive. The associated inverse problem is then to make explicit the structure of non-dispersive sequences over a finite Abelian group. Concerning this problem, W. Gao, Y. Hamidoune and G. Wang recently proved [11] that every non-dispersive sequence of $n$ elements in $C_n$ has at most two distinct values, solving a conjecture of R. Graham reported in a paper of P. Erdős and E. Szemerédi [4]. This result was then generalized by D. Gryniewicz in [14].

In this article, we study a still widely open conjecture, proposed by W. Gao in [7], on the structure of the so-called normal sequences over a finite Abelian group $G$. A sequence $S$ over $G$ with $|S| \geq D(G)$ is said to be normal if all its zero-sum subsequences $S'$ satisfy $|S'| \leq |S| - D(G) + 1$. Gao’s conjecture is the following (see also Conjecture 4.9 in [8]).

**Conjecture 1.** — Let $G \simeq C_{n_1} \oplus \cdots \oplus C_{n_r}$, with $1 < n_1 | \ldots | n_r \in \mathbb{N}$, be a finite Abelian group. Let also $S$ be a normal sequence over $G$ of length $|S| = D(G) + i - 1$, where $i \in [1, n_1 - 1]$. Then $S$ is of the form $S = 0^i T$, where $T$ is a zero-sumfree sequence.

This notion of a normal sequence, first introduced in [7], happens to be crucial in the characterization of sequences $S$ over $G$ with $|S| = D(G) + |G| - 2$ and which do not contain any zero-sum subsequence $S'$ satisfying $|S'| = |G|$ (see Theorem 1.7 in [7]). The following two theorems, due to W. Gao (see Theorems 1.5 and 1.6 in [7]), are the only results known concerning the structure of normal sequences over a finite Abelian group. Before stating these two results on Conjecture 1, we recall that an integer $n \geq 2$ is said to satisfy Property B if every minimal zero-sum sequence over $C_n^2$ with $|S| = 2n - 1$ contains some element repeated $n - 1$ times (see Section 5.8 in [13], and [9], [10], [18] for recent progress). It is conjectured that every $n \geq 2$ satisfies Property B.

**Theorem 1.1.** — Conjecture 1 holds whenever:

(i) $G$ is a finite cyclic group.
(ii) $G \simeq C_n^2$, where $n$ satisfies Property B.
(iii) $G \simeq C_p^r$, where $p \in \{2, 3, 5, 7\}$.

**Theorem 1.2.** — Let $G$ be a finite Abelian group, and let $p$ be the smallest prime divisor of $\exp(G)$. Then Conjecture 1 holds for every integer $i \leq \min(6, p - 1)$.
2. New results and plan of the paper

In this paper, we use the notion of a dispersive sequence to obtain a characterization of short normal sequences over a finite Abelian $p$-group, thus improving both Gao’s results on this problem. The main theorem (Theorem 2.3) is proved in Section 3, yet before giving this general result, we would like to emphasize its consequences.

**Theorem 2.1.** — Let $G$ be a finite Abelian $p$-group, and let $S$ be a normal sequence over $G$ with $|S| = D(G) + i - 1$, where $i \in [1, p-1]$. Then $S$ is of the form $S = 0^iT$, where $T$ is a zero-sumfree sequence.

Firstly, Theorem 2.1 improves Theorem 1.2, by showing that the assumption $i \leq 6$ is unnecessary for finite Abelian $p$-groups. Secondly, it improves Statement (iii) of Theorem 1.1, by settling Conjecture 1 for every elementary $p$-group. More generally, we can derive immediately from Theorem 2.1 the following corollary on Gao’s conjecture.

**Corollary 2.2.** — Conjecture 1 holds for all groups of the form $G \simeq C_p \oplus H$, where $H$ is any finite Abelian $p$-group.

The main result of this paper is deduced from a theorem of N. Alon, S. Friedland and G. Kalai (see Theorem A.1 in [2]), originally proved so as to study the existence of regular subgraphs in almost regular graphs. Our result is the following.

**Theorem 2.3.** — Let $G$ be a finite Abelian $p$-group, and let $S$ be a sequence over $G$ with $|S| = D(G) + i - 1$, where $i \in [1, p]$. Let also $\mathcal{A}$ be any $(i-1)$-subset of $[1, p-1]$. Then $S$ contains a non-empty zero-sum subsequence $S'$ such that $|S'| \not\equiv b \pmod{p}$, for all $b \in \mathcal{A}$.

Consequently, Theorem 2.3 gives the existence of non-empty zero-sum subsequences whose length avoids certain remainders modulo $p$. In addition, this result applies to 'short' sequences, the length of which is close to $D(G)$, thus allowing to tackle Gao’s conjecture, whereas other existing results with a similar flavor (see for instance Theorem 1.2 in [17]) hold for longer sequences only. In particular, Theorem 2.3 provides the following insight into dispersive sequences.

**Corollary 2.4.** — Let $G$ be a finite Abelian $p$-group, and let $S$ be a sequence over $G$ with $|S| = D(G) + i - 1$, where $i \geq 1$. The following two statements hold.

(i) If $i \geq 2$ and $S$ contains a zero-sum subsequence $S'$ with $p \nmid |S'|$, then $S$ is dispersive.

(ii) If $S$ contains no non-empty zero-sum subsequence $S'$ with $p \nmid |S'|$, then $i \leq p-1$, and $S$ has to contain at least $i$ non-empty zero-sum subsequences with pairwise distinct lengths.

In Section 4, we give a proof of Theorem 2.3, in the special case of elementary $p$-groups, using the so-called polynomial method. Since this proof is short and may be relevant in its own right, we will present it in full.

In Section 5, we then prove the following theorem, which extends Statement (ii) of Theorem 1.1 to every finite Abelian group of rank two. The proof of this theorem relies on a structural result obtained by W. Schmid [18], which is a characterization of long minimal zero-sum sequences over these groups, provided that a suitable divisor of their exponent satisfies Property B.
Theorem 2.5. — Let $G \simeq C_m \oplus C_{mn}$, where $m, n \in \mathbb{N}^*$ and $m \geq 2$. Let also $S$ be a normal sequence over $G$ with $|S| = D(G) + i - 1$, where $i \in [1, m - 1]$. If $m$ satisfies Property B, then $S$ is of the form $S = 0^rT$, where $T$ is a zero-sumfree sequence.

Finally, in Section 6, we propose two general conjectures suggested by the results proved in this paper.

### 3. The case of finite Abelian $p$-groups

As announced in Section 2, we prove our Theorem 2.3 by using the following theorem of N. Alon, S. Friedland and G. Kalai (see Theorem A.1 in [2]). Before stating this result, we need to introduce the following notation. Let $\mathbb{Z}$ of $N$. Alon, S. Friedland and G. Kalai (see Theorem A.1 in [2]). Before stating this result, we need to introduce the following notation. Let $\mathbb{Z}$ be a vector with integer coordinates. If $S$ is an integer-valued vector, then there exists a subset $S \subseteq \mathbb{Z}$ such that $S$ contains a basis of $G$, and $S$ is of the form $S = 0^rT$, where $T$ is a zero-sumfree sequence.

Theorem 3.1. — Let $p$ be a prime and let $1 \leq d_1 \leq \cdots \leq d_n$ be $n$ integers. For $1 \leq j \leq n$, let $S_j \subseteq \mathbb{Z}$ be a set of integers containing 0. For $1 \leq i \leq m$, let $(a_{i,1}, \ldots, a_{i,n})$ be a vector with integer coordinates. If

$$m \geq \sum_{j=1}^{n} (p^{d_j} - \text{card}_p(S_j)) + 1,$$

then there exists a subset $\emptyset \subsetneq I \subseteq \{1, \ldots, m\}$ and numbers $s_j \in S_j$ ($1 \leq j \leq n$) such that

$$\sum_{i \in I} a_{i,j} \equiv s_j \pmod{p^{d_j}},$$

for all $1 \leq j \leq n$.

For instance, it may be observed that Theorem 3.1 provides the exact value for the Davenport constant of a finite Abelian $p$-group, which was originally obtained by P. van Emde Boas, D. Kruyswijk and J. Olson (see [3] and [15]).

Indeed, let $G \simeq C_{p^d} \oplus \cdots \oplus C_{p^r}$, where $1 \leq d_1 \leq \cdots \leq d_r \in \mathbb{N}$, be a finite Abelian $p$-group, and let us set $\mathbf{D}^*(G) = \sum_{i=1}^{r} (p^{d_i} - 1) + 1$. On the one hand, an elementary construction (see [13], Proposition 5.1.8) implies that $\mathbf{D}(G) \geq \mathbf{D}^*(G)$. On the other hand, let $(e_1, \ldots, e_r)$ be a basis of $G$, where ord$(e_i) = p^{d_i}$ for all $i \in [1, r]$, and let $S = g_1 \cdots g_m$ be a sequence over $G$ of length $m = \mathbf{D}^*(G)$. Setting $g_i = a_{i,1}e_1 + \cdots + a_{i,r}e_r$ for all $i \in [1, m]$, and $S_j = \{0\}$ for every $j \in [1, r]$, one readily obtains the converse inequality $\mathbf{D}(G) \leq \mathbf{D}^*(G)$ by Theorem 3.1, thus $\mathbf{D}(G) = \mathbf{D}^*(G)$ for every finite Abelian $p$-group.

Using Theorem 3.1, we can now prove the main theorem of this paper.

Proof of Theorem 2.3. — Let $G \simeq C_{p^d} \oplus \cdots \oplus C_{p^r}$, where $1 \leq d_1 \leq \cdots \leq d_r \in \mathbb{N}$, be a finite Abelian $p$-group. Let $(e_1, \ldots, e_r)$ be a basis of $G$, where ord$(e_i) = p^{d_i}$ for all $i \in [1, r]$, and let $S = g_1 \cdots g_m$ be a sequence over $G$ of length $m = \mathbf{D}(G) + i - 1$, where $i \in [1, p]$. The elements of $S$ can be written in the following way:

$$g_1 = a_{1,1}e_1 + \cdots + a_{1,r}e_r,$$

$$\vdots$$

$$g_m = a_{m,1}e_1 + \cdots + a_{m,r}e_r.$$
Now, let us set \( n = r + 1 \) and \( d_n = 1 \). Let also \( \mathcal{A} \) be a \((i - 1)\)-subset of \([1, p - 1]\), and \( \bar{\mathcal{A}} = [0, p - 1] \setminus \mathcal{A} \). For all \( j \in [1, n] \), we set

\[
\mathcal{S}_j = \begin{cases} 
\bar{\mathcal{A}} & \text{if } j = n, \\
\{0\} & \text{otherwise.}
\end{cases}
\]

Since \((p^d_n - \text{card}_p(\mathcal{S}_n)) = (p - |\bar{\mathcal{A}}|) = |\mathcal{A}| = i - 1\), one obtains

\[
\sum_{j=1}^{n} (p^d_j - \text{card}_p(\mathcal{S}_j)) + 1 = D(G) + i - 1 = m.
\]

Therefore, using Theorem 3.1, there exists a subset \( \emptyset \subset I \subset \{1, \ldots, m\} \) such that

\[
\begin{cases}
\sum_{i \in I} a_{i,j} \equiv 0 \pmod{p^d_i} & \text{for all } 1 \leq j \leq r, \\
\sum_{i \in I} 1 = |I| \equiv s \pmod{p} & \text{for some } s \in \bar{\mathcal{A}}.
\end{cases}
\]

Consequently, the sequence \( S' = \prod_{i \in I} g_i \) is a non-empty zero-sum subsequence of \( S \) such that \(|S'| = |I| \neq b \pmod{p}\) for all \( b \in \mathcal{A} \), which is the desired result. \( \square \)

We can now prove Theorem 2.1 and Corollary 2.4.

**Proof of Theorem 2.1.** — We prove this theorem by induction on \( i \in [1, p - 1] \). If \( i = 1 \), the desired result is straightforward. Now, let \( i \geq 2 \), and let us assume that the assertion of Theorem 2.1 is true for every \( 1 \leq k \leq i - 1 \). Let \( S \) be a normal sequence over \( G \) with \(|S| = D(G) + i - 1\), and let \( \mathcal{A} \) be a \((i - 1)\)-subset satisfying \( \{i\} \subset \mathcal{A} \subset [1, p - 1] \). Then, Theorem 2.3 gives the existence of a non-empty zero-sum subsequence \( S' \) of \( S \) such that \(|S'| \neq i \pmod{p}\). In particular, one has \(|S'| \neq i\), and since \( S \) is a normal sequence, we must have \(|S'| \leq i - 1\). Now, let \( T \mid S \) be the sequence such that \( S = TS' \). Then \(|T| = D(G) + k - 1\), where \( 1 \leq k = i - |S'| \leq i - 1\). Moreover, since \( S \) is a normal sequence, every non-empty zero-sum subsequence \( T' \mid T \) has to satisfy \(|T'| \leq k = i - |S'|\), that is \( T \) is also a normal sequence. Therefore, the induction hypothesis applied to \( T \) implies that \( S \) is of the form \( S = 0^kU \). One has \(|U| = D(G) + \ell - 1\), where \( 1 \leq \ell = i - k \leq i - 1 \), and since \( S \) is a normal sequence, every non-empty zero-sum subsequence \( U' \mid U \) has to satisfy \(|U'| \leq \ell = i - k\), that is \( U \) is also a normal sequence. Finally, the induction hypothesis applied to \( U \) implies that \( S \) is of the form \( S = 0^k0^{r-k}V = 0^rV \), where \( V \) is a zero-sumfree sequence over \( G \), which completes the proof. \( \square \)

**Proof of Corollary 2.4.** — (i) Let \( S \) be a sequence over \( G \) with \(|S| = D(G) + i - 1\), where \( i \geq 2 \), such that \( S \) contains a zero-sum subsequence \( S' \) with \( p \nmid |S'| \). Then, one has \(|S'| = qp + r\) for some integers \( q \geq 0 \) and \( r \in [1, p - 1] \). Now, let \( T \) be any subsequence of \( S \) such that \(|T| = D(G) + 2 - 1\). Specifying \( \mathcal{A} = \{r\} \) in Theorem 2.3, we obtain the existence of a non-empty zero-sum subsequence \( T' \mid T \) such that \(|T'| \neq r \pmod{p}\). In particular, one obtains \(|T'| \neq |S'| \pmod{p}\), which implies \(|T'| \neq |S'|\). Since \( T' \) is also a zero-sum subsequence of \( S \), the desired result is proved.

(ii) Let \( S \) be a sequence over \( G \) with \(|S| = D(G) + i - 1\), where \( i \geq 1 \), such that \( S \) contains no non-empty zero-sum subsequence \( S' \) with \( p \nmid |S'| \). If one had \( i \geq p \), we would obtain, specifying \( \mathcal{A} = [1, p - 1] \) in Theorem 2.3, that every subsequence \( T \mid S \) with \(|T| = D(G) + p - 1\) contains a non-empty zero-sum subsequence \( T' \) such that \( p \mid |T'|\),
which contradicts the assumption made on \( S \). Now, we can prove the second part of the assertion, by induction on \( k \in [1, i] \). If \( k = 1 \), then since \( |S| \geq D(G) \), \( S \) has to contain a zero-sum subsequence \( S_1 \) such that \( p \nmid |S_1| \), and we are done. Now, let \( k \in [2, i] \), and let us assume the assertion is true for \( k - 1 \), that is \( S \) contains at least \( k - 1 \) non-empty zero-sum subsequences \( S_1, \ldots, S_{k-1} \) with pairwise distinct lengths. By hypothesis, one has \( p \nmid |S_j| \) for all \( j \in [1, k-1] \), and we can write \( |S_j| = q_j p + r_j \), where \( q_j \geq 0 \) and \( r_j \in [1, p-1] \). Now, let \( A \) be a \((i-1)\)-subset satisfying \( \{r_1, \ldots, r_{k-1}\} \subseteq A \subseteq [1, p-1] \). Then, by Theorem 2.3, we obtain the existence of a non-empty zero-sum subsequence \( S_k \mid S \) such that \( |S_k| \not\equiv b \pmod{p} \) for all \( b \in A \). In particular, \( |S_k| \neq |S_j| \) for all \( j \in [1, k-1] \), and consequently, \( S \) contains at least \( k \) non-empty zero-sum subsequences \( S_1, \ldots, S_k \) with pairwise distinct lengths, and the proof is complete.

\[ \square \]

4. The special case of elementary \( p \)-groups

In this section, we propose an alternative proof of Theorem 2.3, in the special case of elementary \( p \)-groups, which uses an algebraic tool introduced by N. Alon and called Combinatorial Nullstellensatz (see [1] for a survey on this method). This polynomial method uses the fact that a non-zero multivariate polynomial over a field cannot vanish on ‘large’ Cartesian products so as to derive a variety of results in combinatorics, additive number theory and graph theory. This method relies on the following theorem.

**Theorem 4.1 (Combinatorial Nullstellensatz).** — Let \( \mathbb{K} \) be a field and \( f \) be a polynomial in \( \mathbb{K}[x_1, \ldots, x_n] \) of total degree \( \deg(f) \), admitting a monomial of the following form:

\[ x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_n^{\alpha_n} \text{ of degree } \sum_{i=1}^{n} \alpha_i = \deg(f). \]

Then, for any choice of \( n \) subsets \( S_1, \ldots, S_n \subseteq \mathbb{K} \) such that \( |S_i| > \alpha_i \) for all \( i \in [1, n] \), there exists an element \((s_1, \ldots, s_n) \in S_1 \times S_2 \times \cdots \times S_n \) such that one has \( f(s_1, \ldots, s_n) \neq 0 \).

**Proof of Theorem 2.3 in the special case of elementary \( p \)-groups.**

Let \( p \) be a prime, and let \( G \cong C^r_p \) be an elementary \( p \)-group of rank \( r \). Let also \((e_1, \ldots, e_r)\) be a basis of \( G \), and let \( S = g_1 \cdot \ldots \cdot g_m \) be a sequence over \( G \) of length \( m = D(G) + k - 1 \), where \( k \in [1, p] \). The elements of \( S \) can be written in the following way:

\[ g_1 = a_{1,1} e_1 + \ldots + a_{1,r} e_r, \]

\[ \vdots \]

\[ g_m = a_{m,1} e_1 + \ldots + a_{m,r} e_r. \]

Let \( A \) be a \((k-1)\)-subset of \([1, p-1]\), and let also \( P \in \mathbb{F}_p[x_1, \ldots, x_m] \) be the following polynomial over the finite field \( \mathbb{F}_p \) of order \( p \),

\[ P(x_1, \ldots, x_m) = \prod_{h=1}^{r} \prod_{j=1}^{p-1} \left( \sum_{i=1}^{m} a_{i,h} x_i^{p-1} - j \right) \prod_{j \in A} \left( \sum_{i=1}^{m} x_i^{p-1} - j \right) - \delta \prod_{i=1}^{m} (x_i^{p-1} - 1), \]

\[ 6 \]
where $\delta \in \mathbb{F}_p$ is chosen such that $P(0, \ldots, 0) = 0$. In particular, since no element of $A$ is a multiple of $p$, one has $\delta \neq 0$. Moreover, the total degree of

$$
\prod_{h=1}^{r} \prod_{j=1}^{p-1} \left( \sum_{i=1}^{m} a_{i,h}x_i^{p-1} - j \right) \prod_{j \in A} \left( \sum_{i=1}^{m} x_i^{p-1} - j \right)
$$

being $(r(p - 1) + (k - 1))(p - 1) = (D(G) + k - 2)(p - 1) < m(p - 1)$, we deduce that $\deg(P) = m(p - 1)$. Now, since the coefficient of $\prod_{i=1}^{m} x_i^{p-1}$ is $-\delta \neq 0$, Theorem 4.1 implies that there exists a non-zero element $x = (x_1, \ldots, x_m) \in \mathbb{F}_p^m$ such that $P(x_1, \ldots, x_m) \neq 0$. Consequently, setting $I = \{i \in [1, m] \mid x_i \neq 0\}$, we obtain that $S' = \prod_{i \in I} g_i$ is a non-empty zero-sum subsequence of $S$ satisfying $|S'| = |I| \neq b \pmod{p}$ for all $b \in A$, which completes the proof.

5. The case of finite Abelian groups of rank two

In this section, we prove a result extending Statement $(ii)$ of Theorem 1.1 to every finite Abelian group of rank two. The proof of this theorem relies on the following result of W. Schmid [18], which gives a structural characterization of minimal zero-sum sequences of length $D(G) = m + mn - 1$ over the group $G \simeq C_m \oplus C_{mn}$, where $m, n \in \mathbb{N}^*$ and $m \geq 2$, under the hypothesis that $m$ satisfies Property B.

**Theorem 5.1.** Let $G \simeq C_m \oplus C_{mn}$, where $m, n \in \mathbb{N}^*$ and $m \geq 2$, be a finite Abelian group of rank two. The following sequences are minimal zero-sum sequences of maximal length.

(i) $S = e^{\text{ord}(e_2)}_{j} \prod_{i=1}^{\text{ord}(e_2)} (-x_i e_j + e_k)$ where $(e_1, e_2)$ is a basis of $G$ with $\text{ord}(e_2) = mn$, $\{j, k\} = \{1, 2\}$, and $x_i \in \mathbb{N}$ with $\sum_{i=1}^{n+1-s} x_i \equiv -1 \pmod{\text{ord}(e_j)}$.

(ii) $S = g_1^{m-1} \prod_{i=1}^{(n+1-s)m} (-x_i g_1 + g_2)$ where $s \in [1, n]$, $\{g_1, g_2\}$ is a generating set of $G$ with $\text{ord}(g_2) = mn$ and such that $s = 1$ or $mg_1 = mg_2$, and $x_i \in \mathbb{N}$ with $\sum_{i=1}^{(n+1-s)m} x_i = m - 1$.

In addition, if $m$ satisfies Property B, then all minimal zero-sum sequences of maximal length over $G$ are of this form.

Moreover, W. Gao and J. Zhuang proved a useful structural result on normal sequences (see Theorem 1.2 in [7]). In this section, we will use the following corollary of this theorem.

**Theorem 5.2.** Let $G$ be a finite Abelian group, and let $S$ be a normal sequence over $G$. Then $S$ is of the form $S = 0^kTU$, where $T$ is a zero-sum-free sequence with $|T| = D(G) - 1$, and $U$ is a sequence over $G$ such that $\text{Supp}(U) \subseteq \text{Supp}(T)$.

Using the two above results, we can now prove the following theorem.

**Theorem 5.3.** Let $G \simeq C_m \oplus C_{mn}$, where $m, n \in \mathbb{N}^*$ and $m \geq 2$, be a finite Abelian group of rank two. Let $T$ be a zero-sum-free sequence over $G$ with $|T| = D(G) - 1$ and let $U$ be a non-empty sequence over $G$ such that $\text{Supp}(U) \subseteq \text{Supp}(T)$. If $m$ satisfies Property B, then every non-empty zero-sum subsequence $S'$ of $S = TU$ has length $|S'| \geq m$. 

7
Proof of Theorem 5.3. — Let $G$ and $S = TU$ be as in the statement of the theorem. By Theorem 5.1, and since $T' = T(-\sigma(T))$ is a minimal zero-sum sequence over $G$, $S = TU$ can be written in the following fashion

$$S = g_1^{\ell_1} \prod_{i=1}^{\ell_2} (-x_ig_1 + g_2),$$

where $\{g_1, g_2\}$ is a generating set of $G$ with $\text{ord}(g_2) = mn$, and $\ell_1, \ell_2 \in \mathbb{N}$ are such that $\ell_1 + \ell_2 = |S|$. In particular, one has $mg_1 \in \langle mg_2 \rangle$, and $ag_1 \in \langle g_2 \rangle$ if and only if $m \mid a$. Since $|S| \geq D(G)$, it has to contain a non-empty zero-sum subsequence $S'$. Now, let us write $S' = VW$ where $V \mid g_1^{\ell_1}$ and $W = \prod_{i \in I} (-x_ig_1 + g_2)$, for some $I \subseteq [1, \ell_2]$. We obtain

$$\sigma(S') = |V|g_1 - \left(\sum_{i \in I} x_i\right)g_1 + |W|g_2 = 0.$$ 

Since $\sigma(S') = 0 \in \langle g_2 \rangle$, we have

$$m \mid |V| - \left(\sum_{i \in I} x_i\right)$$

which implies that, for some $a \in \mathbb{N}$, one has

$$|V| - \left(\sum_{i \in I} x_i\right) = amg_2.$$ 

Thus, $\sigma(S') = (am + |W|)g_2 = 0$, which gives $m \mid \text{ord}(g_2) \mid am + |W|$. Consequently, $m \mid |W|$. If $|W| \geq m$, then we are done. Otherwise, one has $|W| = |I| = 0$, and $\sigma(S') = |V|g_1 = 0 \in \langle g_2 \rangle$. Thus, $m \mid |V| = |S'|$, and since $S'$ is a non-empty zero-sum subsequence of $S$, we obtain $|S'| \geq m$, which is the desired result. 

Theorem 2.5 is now an easy corollary of Theorem 5.3.

Proof of Theorem 2.5. — Let $G \simeq C_m \oplus C_{mn}$, where $m, n \in \mathbb{N}^*$ and $m \geq 2$, be a finite Abelian group of rank two. Let also $S$ be a normal sequence over $G$ with $|S| = D(G) + i - 1$, where $i \in \llbracket 1, m - 1 \rrbracket$. By Theorem 5.2, $S$ is of the form $S = 0^kTU$, where $T$ is a zero-sumfree sequence with $|T| = D(G) - 1$, and $U$ is a sequence over $G$ such that $\text{Supp}(U) \subseteq \text{Supp}(T)$. Since $m > i$, $S$ does not contain any zero-sum subsequence $S'$ with $|S'| \geq m$. So, it follows from Theorem 5.3 that $U$ is empty, which implies $k = i$ and completes the proof. 

6. Two concluding remarks

In this section, we would like to present two conjectures suggested by the results proved in this paper. The first one may be interpreted as a more general version of Theorem 2.3, and would imply Conjecture 1 in the same way as Theorem 2.3 implies Theorem 2.1.

Conjecture 2. — Let $G \simeq C_{n_1} \oplus \cdots \oplus C_{n_r}$, with $1 < n_1 \mid \ldots \mid n_r \in \mathbb{N}$, be a finite Abelian group, and let $S$ be a sequence over $G$ with $|S| = D(G) + i - 1$, where $i \in \llbracket 1, n_1 \rrbracket$. 

8
Let also $A$ be any $(i - 1)$-subset of $\llbracket 1, n_1 - 1 \rrbracket$. Then $S$ contains a non-empty zero-sum subsequence $S'$ such that

$$|S'| \not\equiv b \pmod{n_1}, \text{ for all } b \in A.$$  

Let $G$ be a finite Abelian group of exponent $m$. By $s_{mN}(G)$ we denote the smallest $t \in \mathbb{N}^*$ such that every sequence $S$ over $G$ with $|S| \geq t$ contains a non-empty zero-sum subsequence $S'$ with $|S'| \equiv 0 \pmod{m}$. The exact value of the invariant $s_{mN}(G)$ is currently known for finite Abelian groups of rank $r \leq 2$, and finite Abelian $p$-groups only (see Theorem 6.7 in [8]). For instance, Conjecture 2 implies that for all integers $n, r \geq 1$, one has $s_{mN}(C_n^r) = (r + 1)(n - 1) + 1$. This conjecture would also help to tackle the inverse problem associated to $s_{mN}(G)$, by giving an account of the variety of zero-sum subsequences contained in a long sequence without any non-empty zero-sum subsequence of length congruent to 0 modulo $m$. Finally, any progress on this conjecture would provide a new insight on the structure of sequences over $C_n$ without any zero-sum subsequence of length $n$ (see Theorem 7.5 and Conjecture 7.6 in [8], as well as [16]).

Let $G$ be a finite Abelian group of order $n$ and exponent $m$. For instance, if $\ell = 1$ in Conjecture 3, one obtains a generalization of Conjecture 6.5 in [8], due to W. Gao. If $\ell = n/m$, then, since it is known that $D(G) \leq n = \ell m$, we obtain $\eta_{\ell m}(G) = D(G)$. Therefore, Conjecture 3 implies that every sequence $S$ over $G$ with $|S| = D(G) + i - 1$, where $i \in \llbracket 1, n \rrbracket$, has to contain a zero-sum subsequence $S'$ with $i \leq |S'| \leq n$, which can be seen as a generalization of Gao’s theorem (see Theorem 1 in [5]). Finally, if $\ell = [D(G)/m]$ and $i = \ell m$, then Conjecture 3 implies that every sequence $S$ over $G$ with $|S| = D(G) + \ell m - 1$ has to contain a zero-sum subsequence $S'$ with $|S'| = \ell m$, which would provide an answer to a problem of W. Gao (see Section 3 in [6] and Theorem 6.12 in [8]).
