HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Finite Projective Spaces, Geometric Spreads of Lines
and Multi-Qubits

Abstract
Given a \((2^N - 1)\)-dimensional projective space over GF(2), \(PG(2^N - 1, 2)\), and its geometric
spread of lines, there exists a remarkable mapping of this space onto \(PG(N - 1, 4)\) where the
lines of the spread correspond to the points and subspaces spanned by pairs of lines to the
lines of \(PG(N - 1, 4)\). Under such mapping, a non-degenerate quadric surface of the former
space has for its image a non-singular Hermitian variety in the latter space, this quadric
being hyperbolic or elliptic in dependence on \(N\) being even or odd, respectively. We employ
this property to show that generalized Pauli groups of \(N\)-qubits also form two distinct families according to the parity of \(N\) and to put the role of symmetric Pauli operators into a
new perspective. The \(N = 4\) case is taken to illustrate the issue, due to its link with the
so-called black-hole/qubit correspondence.

Multiple qubit states play a key role in various fields of quantum information theory
like quantum computing, coding and quantum error-correction (see, e.g., [1]). Recently,
and rather surprisingly, they have also been recognized to be of great relevance for getting
insights into the nature of entropy formulas of a certain class of stringy black hole solutions
(see, e.g., [2]). It is, therefore, important to deepen our understanding of these fundamental
buildings blocks of quantum world. In the present note we do so through the geometry of
their associated generalized Pauli groups.

Let \(PG(d, q)\) be a \(d\)-dimensional projective space over GF\((q)\), \(q\) being a power of a prime.\(^1\)
A \(t\)-spread \(S\) of \(PG(d, q)\) is a set of \(t\)-dimensional subspaces of \(PG(d, q)\) which partitions its
point-set \(\mathbb{P}d\). If the elements of \(S\) in a subspace \(V\) form a \(t\)-spread on \(V\), one says that \(S\)
induces a \(t\)-spread on \(V\). A \(t\)-spread \(S\) is called geometric (or normal) if it induces a \(t\)-spread
on each \((2t + 1)\)-dimensional subspaces of \(PG(d, q)\) spanned by a pair of its elements. It
is a well-known fact that \(PG(d, q)\) possesses a \(t\)-spread iff \((t + 1)\) \(\mid (d + 1)\); moreover, this
condition is also sufficient for \(PG(d, q)\) to have a geometric \(t\)-spread. B. Segre showed \(\square\)
that a geometric \(t\)-spread of \(PG(N(t + 1) - 1, q)\), \(N \geq 2\), gives rise to a projective space
\(PG(N - 1, q^{t+1})\) as follows: the points of this space are the elements of \(S\) and its lines are the
\((2t + 1)\)-dimensional subspaces spanned by any two distinct elements of \(S\), with incidence
inherited from \(PG(N(t + 1) - 1, q)\). For a particular case of \(t = 1\) (i.e., a spread of lines), Dye
\(\square\) demonstrated that a hyperbolic or an elliptic quadric of \(PG(2N - 1, q)\) has an induced
(geometric) spread of lines if and only if \(N\) is, respectively, even or odd, in which case it is
mapped onto a non-singular Hermitian variety \(H(N - 1, q^2)\) of \(PG(N - 1, q^2)\). We shall now
show that this property has for \(q = 2\) a very interesting physical implication.

It is already a firmly established fact \(\square\) that the commutation relations between the elements of the generalized Pauli group of \(N\)-qubits, \(N \geq 2\), can be completely reformulated in the geometrical language of symplectic polar space of rank \(N\) and order
two, \(W(2N - 1, 2);\) the generalized Pauli operators (discarding the identity) answer to the

\(^1\)For the standard mathematical nomenclature and notation employed in what follows, see, e.g., [3].
points of $W(2N - 1, 2)$, a maximally commuting subset has its representative in a maximal totally isotropic subspace of $W(2N - 1, 2)$ and commuting translates into collinear. One of the most natural representations of $W(2N - 1, 2)$ is that in terms of the points and the set of totally isotropic subspaces of $PG(2N - 1, 2)$ endowed with a symplectic polarity. Employing this representation, it has been found in [8] that in the real case the symmetric elements/operators of the $N$-qubit Pauli group always lie on a hyperbolic quadric in the ambient space $PG(2N - 1, 2)$. Combining this fact with Dye’s result, we arrive at our main observation: it is only for $N$ even when all symmetric generalized Pauli operators of $W(2N - 1, 2)$ can be mapped to the points of an Hermitian variety of the space $PG(N - 1, 4)$ associated through a geometric spread of lines with the ambient space $PG(2N - 1, 2)$. Hence, in this regard, when it comes to generalized Pauli groups ‘even-numbered’ multi-qubits are found to stand on a slightly different footing than ‘odd-numbered’ ones.

We shall finish this communication by briefly mentioning an especially interesting even case, $N = 4$. Here, a hyperbolic quadric $Q^+(7, 2)$ of $PG(7, 2)$ formed by the symmetric operators is well known for its puzzling triality swapping points and two systems of generators and has for its spread-induced image an Hermitian surface $H(3, 4)$ of $PG(3, 4)$ (see, e.g., [11]). This Hermitian surface is, in turn, nothing but the generalized quadrangle $GQ(4, 2)$ in disguise (see, e.g., [12]), the dual of which — $GQ(2, 4)$ — was found to play a prominent role in the so-called black-hole-qubit correspondence, by fully encoding the $E_{6(6)}$ symmetric entropy formula describing black holes and black strings in $D = 5$ [13]. Our finding thus, \textit{inter alia}, not only opens up an unexpected window through which also four-qubit Pauli group, like its lower rank cousins, could find its way into some black hole entropy formula(s), but also puts the role of symmetric operators into a new perspective. It is also important to keep in mind this remarkable \textit{three-to-one} correspondence, i.e., that it is always a triple of (collinear) operators of the ambient space $PG(7, 2)$ which comprises a single point of $PG(3, 4)$.
