Résumé

Dans ce papier, nous examinons empiriquement l'impact de l'adoption du ciblage d'inflation sur le pass-through du taux de change dans les pays émergents. Nous utilisons une approche en panel VAR qui nous permet d'utiliser un grand échantillon sur vingt-sept pays émergents (quinze cibleurs d'inflation et douze non-cibleurs d'inflation). Nos résultats montrent que l'adoption du ciblage d'inflation dans les pays émergents a permis de réduire le pass-through du taux de change sur divers indices de prix (prix des imports, prix des producteurs et prix de la consommation) d'un niveau très élevé à un nouveau niveau qui est significativement différent de zéro. L'analyse de la décomposition de la variance montre que la contribution des chocs de taux de change dans la fluctuation des prix est élevée dans les pays cibleurs que dans les pays non-cibleurs, et la contribution des chocs de taux de change dans la fluctuation des prix dans les pays cibleurs a baissé après l'adoption du ciblage d'inflation.

Mots-clés : Ciblage d'inflation, Pass-through du taux de change, panel VAR.

Abstract

In this paper, we empirically examine the effect of inflation targeting on the exchange rate pass-through to prices in emerging countries. We use a panel VAR that allows us to use the larger data set on twenty-seven emerging countries (fifteen inflation targeters and twelve inflation nontargeters). Our evidence suggests that inflation targeting in emerging countries has helped to reduce the pass-through to various price indexes (import prices, producer prices and consumer prices) from a higher level to a new level that is significantly different from zero. The variance decomposition shows that the contribution of exchange rate shocks to prices fluctuations is more important in emerging targeters compared to nontargeters, and the contribution of exchange rate shocks to price fluctuations in emerging targeters declines after adopting inflation targeting.

Keywords : Inflation Targeting, Exchange Rate Pass-Through, panel VAR.

JEL classification : E31, E52, F41.

1 Introduction

After New Zealand initiated inflation targeting in 1990, a large number of industrial and emerging countries have explicitly adopted an inflation target as their nominal anchor. In the last two decades, ten industrial economies and twenty emerging economies¹ have adopted the full-fledged inflation targeting system for managing monetary policy. Many other emerging countries are intend to adopt this monetary framework in the near future. Given the vulnerability of emerging countries to exchange rate shocks, a key element for the success of this strategy depends on its ability to reduce the exchange rate pass-through. Various studies have shown a decrease in exchange rate pass-through in the last two decades : is it related to inflation targeting ?

Many studies have provided some evidence that adoption of inflation targeting is associated with an improvement in overall economic performance (Bernanke and Mishkin (1997) ; Svensson (1997) ; Bernanke et al.(1999) among others). Ball and Sheridan (2005), one of the few empirical papers critical of inflation targeting, argue that implementation of inflation targeting appears to have been irrelevant in industrial countries. Precisely, based on OLS cross-section estimation, their results indicate that the reduction in the level and the volatility of inflation in inflation targeting countries simply reflects regression toward the mean, i.e., inflation will fall faster in countries that start with high inflation than in countries with an initial low inflation. Since countries having implemented inflation targeting had generally an initial high level of inflation, the bigger drop in inflation for those countries simply reflects a tendency for this variable to revert to its mean. But, as their study focused solely on industrial countries, their results suffer from a selection bias problem. Gonçalves and Salles (2008) extended Ball and Sheridan's analysis for a subset of 36 emerging economies and found that, for those countries, the results are different. Specifically, countries which have adopted inflation targeting have experienced greater reductions in inflation and in growth volatility, even after controlling for mean reversion.

The present paper contributes to this literature on inflation targeting by analyzing the effect of inflation targeting on exchange rate pass-through in emerging countries. It is based on the hypothesis in Taylor (2000) that argues that exchange rate pass-through is lower in low-inflation environment.

1. The ten industrial countries targeters are Australia, Canada, Finland, New Zealand, Norway, Spain, Sweden, Switzerland and United Kingdom. Finland and Spain are now in euro area. The twenty emerging countries targeters are Brazil, Chile, Colombia, Czech republic, Ghana, Guatemala, Hungary, Indonesia, Israel, Korea, Mexico, Peru, Philippines, Poland, Romania, Serbia, Slovakia, South Africa, Thailand and Turkey. Slovakia ceased inflation targeting in January 2009 with its ERM II entry

More precisely Taylor's argument is that in low-inflation environment firms expect a deviation of inflation to be less persistent and would therefore pass on less of an exchange rate-induced increase in the price of imported inputs to its selling prices. This hypothesis has been supported by empirical evidence based on consumer price index (CPI), both for industrialized and emerging countries (see for example Gagnon and Ihrig (2001) or Choudhri and Hakura (2006)). Since Gonçalves and Salles (2008) show that inflation targeting has helped to reduce inflation in emerging countries, it is interesting to analyze whether the adoption of inflation targeting has led to a decrease in exchange rate pass-through. This idea was explored by Mishkin and Schmidt-Hebbel (2007). Mishkin and Schmidt-Hebbel (2007) empirically study the link between inflation targeting and some measures of economic performance including exchange rate pass-through. Using data on twenty-one industrial and emerging inflation-targeting countries (targeters) and thirteen industrial countries without inflation targeting (nontargeters) they employ panel VAR techniques. To test for differences, they adopt the difference-in-difference approach by comparing impulse response functions in different country samples, depending on whether a country has inflation targeting in place. The results of this analysis show that pass-through effect to consumer prices has been close to zero in industrial inflation targeters before and after inflation targeting and in nontargeters. But in emerging inflation targeters, the exchange rate pass-through to consumer prices fell after the countries achieved a stationary target but remains positive and significantly different from zero.

However, these of results Mishkin and Schmidt-Hebbel (2007) suffer from a selection bias as there is no emerging inflation nontargeters in the control group. This raises the following question : Does, by using emerging inflation nontargeters as control group, the exchange rate pass-through effect decreases in emerging countries targeters after adopting inflation targeting ? To answer this question, we extend Mishkin and Schmidt-Hebbel's analysis to a subset of twenty-seven emerging economies (fifteen targeters and twelve nontargeters). After a first VAR analysis by including the consumer prices (CPI) as the only price, we conduct a second VAR analysis by including two other prices : import prices (IMP) and producer prices (PPI). The use of these two prices in the VAR allows us to directly answer to the Taylor's hypothesis. A decrease in pass-through effect to import prices means that after the adoption of inflation targeting a retailing firm that imports goods from abroad absorbs a larger fraction of an exchange rate shock through a smaller variation in its selling prices. A decrease in pass-through effect to producer prices means that after the adoption of inflation targeting, a firm that imports its inputs from abroad absorbs a larger fraction of an exchange rate shock through a

smaller variation in the prices of its final products.

The main results of this paper are the following. The adoption of inflation targeting in emerging countries has helped to reduce the pass-through to consumer prices from a initial higher level to a new level that, however, remains significantly different from zero. For emerging nontargeters the story is different, the pass-through to consumer prices has not been significantly different from zero before 1999 and has significantly become positive after 1999. By comparing emerging inflation targeters after adopting inflation targeting to emerging nontargeters after 1999, the pass-through effects to consumer prices are not significantly different among the two groups of emerging targeters and nontargeters. Finally, the decline in pass-through to consumer prices in emerging inflation targeters is attributable to the decline in pass-through effect along the prices chain. In fact, the pass-through effects to both import and producer prices fell significantly in emerging inflation targeters after adopting inflation targeting framework.

The remainder of the paper is organized as follows. Section 2 presents methodology and data. Section 3 presents the empirical results and their interpretations. Section 4 concludes the study.

2 Methodology and Data

Our quarterly dataset consists of twenty-seven emerging economies (fifteen inflation targeters and twelve inflation nontargeters), covering the 1989Q1-2009Q1 period. Using the panel VAR difference-in-difference strategy employed by Mishkin and Schmidt-Hebbel (2007), we investigate whether, considering emerging nontargeters as control group, inflation targeting has helped to reduce the exchange rate pass-through to domestic prices in emerging countries.

We use panel VAR techniques to estimate the impulse response functions. The use of panel VAR techniques has two main advantages. First, the VAR approach addresses the endogeneity problem by allowing endogenous interactions between the variables in the system. Second, the asymptotic results are easier to derive for panel data.

The econometric model takes the following reduced form :

$$Y_{it} = \Gamma(L)Y_{it} + u_i + \epsilon_{it} \quad (1)$$

where Y_{it} is a vector of stationary variables, $\Gamma(L)$ is a matrix polynomial in the lag operator with $\Gamma(L) = \Gamma_1 L^1 + \Gamma_2 L^2 + \dots + \Gamma_p L^p$, u_i is a vector of country specific effects and ϵ_{it} is a vector of idiosyncratic errors.

An issue in estimating this model concerns the presence of fixed effects. As fixed effects are correlated with the regressors, due to lags of the dependent variable, we use forward mean differencing (the Helmert procedure), following Love and Zicchino (2006). In this procedure, to remove the fixed effects, all variables in the model are transformed in deviations from forward means. Let $\bar{y}_{it}^m = \sum_{s=t+1}^{T_i} y_{is}^m / (T_i - t)$ denote the means obtained from the future values of y_{it}^m , a variable in the vector $Y_{it} = (y_{it}^1, y_{it}^2, \dots, y_{it}^M)'$, where T_i denotes the last period of data available for a given country series. Let $\bar{\epsilon}_{it}^m$ denote the same transformation of ϵ_{it}^m , where $\epsilon_{it} = (\epsilon_{it}^1, \epsilon_{it}^2, \dots, \epsilon_{it}^M)'$. Hence we get :

$$\tilde{y}_{it}^m = \delta_{it}(y_{it}^m - \bar{y}_{it}^m) \quad (2)$$

and

$$\tilde{\epsilon}_{it}^m = \delta_{it}(\epsilon_{it}^m - \bar{\epsilon}_{it}^m) \quad (3)$$

where $\delta_{it} = \sqrt{(T_i - t) / (T_i - t + 1)}$. For the last year of data this transformation cannot be calculated, since there are no future value for the construction of the forward means. The final transformed model is thus given by :

$$\tilde{Y}_{it} = \Gamma(L)\tilde{Y}_{it} + \tilde{\epsilon}_{it} \quad (4)$$

where $\tilde{Y}_{it} = (\tilde{y}_{it}^1, \tilde{y}_{it}^2, \dots, \tilde{y}_{it}^M)'$ and $\tilde{\epsilon}_{it} = (\tilde{\epsilon}_{it}^1, \tilde{\epsilon}_{it}^2, \dots, \tilde{\epsilon}_{it}^M)'$

This transformation is an orthogonal deviation, in which each observation is expressed as a deviation from average future observations. Each observation is weighed so as to standardize the variance. If the original errors are not autocorrelated and are characterized by a constant variance, the transformed errors should exhibit similar properties. Thus, this transformation preserves homoscedasticity and does not induce serial correlation (Arellano and Bover, 1995). Additionally, this technique allows to use the lagged values of regressors as instruments and estimate the coefficients by the generalized method of moment (GMM).

Once all coefficients of the panel VAR are estimated, we compute the impulse response functions (IRFs).² In order to compute the IRFs we use Cholesky decomposition. The assumption behind Cholesky decomposition is that series listed earlier in the VAR order impact the others variables contemporaneously, while series listed later in the VAR order impact those listed earlier

2. The panel VAR is estimated by using the package provided by Inessa Love. This package is a Stata programs for Love (2001) and it is used in Love and Zicchino (2006).

only with lag. Consequently, variables listed earlier in the VAR order are considered to be more exogenous.

We apply bootstrap methods to construct the confidence intervals of the IRFs. Since we cannot assume independence among the various samples, we also employ bootstrap methods to construct confidence intervals for differences in IRFs rather than simply taking their differences.³

Following Ito and Sato (2007, 2008)⁴, we set up a 5-variable VAR model, $Y_{it} = (\Delta oil_{it}, gap_{it}, \Delta m_{it}, \Delta ner_{it}, \Delta cpi_{it})'$, where *oil* denotes the natural log of world oil prices; *gap* the output gap; *m* the natural log of money supply; *ner* that of the nominal exchange rate; *cpi* that of the consumer price index (CPI); and Δ represents the first difference operator. The change in oil prices is included to identify the supply shock. We include the output gap to capture the demand side. The money supply is included in the VAR to allow for the effect of monetary policy in response to a large fluctuation in exchange rate or devaluation.

To answer directly the Taylor conjecture, we also attempt to conduct an additional estimation with 7-variable VAR model by including two other price indexes : the producer price index (PPI) and the import price index (IMP). As mentioned above, a decrease in the pass-through effect on import prices will mean that retail firms that import their commodities pass through a lower fraction of an exchange rate shock into their selling prices; and, a decrease in the pass-through effect on producer prices will mean that firms that import their inputs pass through a lower fraction on such a shock into the final goods prices. According to Burstein, Eichenbaum and Rebelo (2002, 2005), the extent of CPI inflation after a large changes in exchange rate depends on the relative importance of imported inputs being used for domestic production and the presence of distribution costs. The production or distribution channels can dampen the effect of exchange rate changes and account for a low pass-through to consumer prices. Then, the 7-variable VAR model allows us to examine the exchange rate pass-through along the pricing chain. In other words, it allows us to examine whether inflation targeting could have negatively impacted on the pass-through to consumer prices by lowering pass-through to imported and/or producer prices.

As discussed above, the order of endogenous variables is central to the identification of structural shocks. The change in oil prices included to identify the supply shock is ordered first in the VAR. The output gap is placed

3. If we assume sample independence, the confidence intervals for differences in IRFs would be narrower.

4. Ito and Sato (2007) used VAR technique to compare the exchange rate pass-through effects of East Asia and Latin American Countries, while Ito and Sato (2008) applied VAR analysis to exchange rate pass-through in East Asian countries .

second. The demand and supply shocks that affect the output gap are assumed to be predetermined. The money supply is ordered third and before the nominal exchange rate and the price variables. Then, for the 5-variable VAR the ordering is : $\Delta oil, gap, \Delta m, \Delta ner, \Delta cpi$. In 7-variable VAR it seems appropriated to place import prices ahead of producer and consumer prices and to place consumer prices last in the ordering. Thus, for the 7-variable VAR the ordering is : $\Delta oil, gap, \Delta m, \Delta ner, \Delta imp, \Delta ppi, \Delta cpi$.

3 Empirical Results

This section presents the results of the impulse response function analysis. The details of the data for empirical estimation are presented in the appendix. Before conducting the structural VAR estimation, we tested for stationarity. Since the oil price is a variable that does not depend on countries, the stationarity test on this variable is conducted by using the standard Augmented Dickey-Fuller unit root test. For the other variables, we use Maddala and Wu (1999) panel unit root test. The tests results (see Table 1) show that the oil price, three types of domestic prices, the money supply and the nominal exchange rate are non-stationary in level but stationary in first-differences for all countries. The output gap is found to be stationary in level. Previous studies (for example Ito, T. and K. Sato 2007, 2008, Mishkin, F. and K. Schmidt-Hebbel, 2007) suggest to include in a VAR the output gap in level together with other variables in first-difference. We follow this methodology in our structural VAR analysis. The model yields similar IRFs when we include two lags or more. Hence, we selected a lag order of two for reasons of parsimony.

We start by discussing the impulse responses of CPI to an exchange rate shock in the 5-variable VAR model for targeters and nontargeters. We also discuss the impulse responses of all prices (CPI, PPI and IMP) to an exchange rate shock in the 7-variable VAR model for targeters.

3.1 Comparison of Exchange pass-through to domestic CPI of targeters and nontargeters

In this subsection we discuss the impulse responses of CPI to an exchange rate shock in the 5-variable VAR model for targeters and nontargeters. The impulse responses for the different samples are reported in Figures 1-3. Each figure focuses on a comparison between the dynamic response of two sample groups. Figure 1 reports before-and-after comparisons for inflation targeters before and after adopting inflation targeting. Figure 2 reports before-and-

TABLE 1 – Unit Root test

Variables	P-value
<i>oil</i>	0.4644
Δoil	0.0000
<i>g</i>	0.0000
<i>m</i>	0.4642
Δm	0.0000
<i>ner</i>	0.8206
Δner	0.0000
<i>cpi</i>	0.6313
Δcpi	0.0000
<i>imp</i>	0.1448
Δimp	0.0000
<i>ppi</i>	0.4041
Δppi	0.0000

Note : The unit root test for *oil* and Δoil is Augmented Dickey-Fuller (ADF) test since these variables do not depend on countries (the p-value is MacKinnon approximate p-value). The null hypothesis of the ADF test is that the variable is non-stationary. For other variables, the unit root test is the panel unit root test developed by Maddala and Wu (1999) with the the null hypothesis that all series are non-stationary against the alternative that at least one series in the panel is stationary. The test is implemented by Stata module *xtfisher*. No lag is used for *g*. 4 lags are used for *oil*. 13, 5 , 8, 7, and 9 lags are used for *m*, *ner*, *cpi*, *imp* and *ppi*, respectively. Using a lag length higher, the results were still found to be the same. For the level of variables, constant and time trend are included. For the first-difference of variables, only constant is included.

after comparisons for inflation nontargeters before and after 1999⁵. Figure 3 reports comparisons across the two sample of targeters and nontargeters : inflation targeters after adopting inflation targeting are compared to nontargeters after 1999. In these figures the third cell reports the difference between the two preceding responses (the response in the second cell minus the response in the first cell).

Figure 1 shows a positive significant exchange rate pass-through to consumer prices in inflation targeting countries that decreases after they adopted inflation targeting. As reflected by the confidence intervals in third cell, the decrease in exchange rate pass-through to consumer prices is statistically different from zero. As reported in Figure 2, for nontargeters the exchange

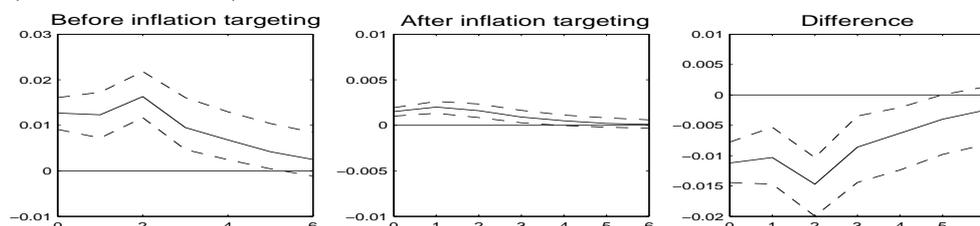

5. 1999 is around the average of the adoption date of inflation targeting in emerging countries. We also ran estimations using, 1998, and 2000 as the demarcation periods. These changes did not substantially affect our results.

rate pass-through to CPI has not been significantly different from zero before 1999 and has become significantly positive after 1999. Figure 3 shows that the exchange rate pass-through to consumer prices is the same for targeters after inflation targeting and nontargeters after 1999.

We reach some conclusions from our comparison of dynamics of pass-through effects from exchange rate shocks to domestic consumer prices. First, the adoption of inflation targeting in emerging countries has helped to reduce the pass-through from a higher level, and the pass-through effect remains significantly different from zero. Second, for emerging nontargeters, the pass-through has not been significantly different from zero before 1999 and becomes significantly positive after 1999. Finally, by comparing emerging inflation targeters after adopting inflation targeting to emerging nontargeters in recent years, the pass-through effects are not significantly different among the two groups of emerging targeters and nontargeters.

The decrease in the exchange pass-through to consumer prices can be attributable to the decline in the exchange rate pass-through to import or domestic producer prices. In the next subsection we will focus on the characteristics of this mechanism.

FIGURE 1 – Response of CPI to an exchange rate shock : Emerging targeters (5-variable VAR)

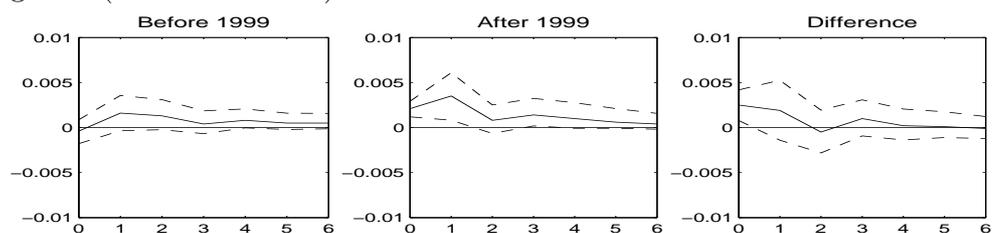

Note : The solid line shows the impulse response to an exchange rate shock. The dashed lines indicate five standard error confidence band around the estimate. Error are generated by Monte-Carlo with 500 repetitions.

3.2 Exchange Rate pass-through along pricing chain in emerging inflation targeters

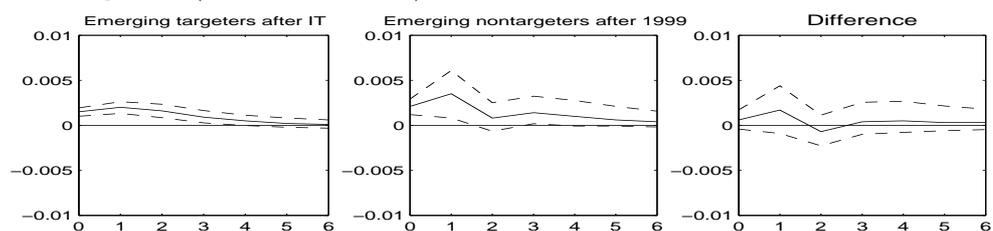

In the previous subsection, we have obtained evidence that inflation targeting has helped the exchange rate pass-through to consumer prices to decrease. As discussed above, the response of consumer prices to changes in exchange rate depends on the extent of imported inputs being used for domestic production and the presence of distribution costs. The production or distribution channels can dampen the effect of exchange rate changes on consumer

FIGURE 2 – Response of CPI to an exchange rate shock : Emerging nontargeters (5-variable VAR)

Note : The solid line shows the impulse response to an exchange rate shock. The dashed lines indicate five standard error confidence band around the estimate. Error are generated by Monte-Carlo with 500 repetitions.

FIGURE 3 – Response of CPI to an exchange rate shock : targeters versus nontargeters (5-variable VAR)

Note : The solid line shows the impulse response to an exchange rate shock. The dashed lines indicate five standard error confidence band around the estimate. Error are generated by Monte-Carlo with 500 repetitions.

prices and account for a low exchange rate pass-through to consumer prices. In order to take into account the production and distribution channels we estimate a 7-variable VAR that includes two other price indexes : the producer price index (PPI) and the import price index (IMP). This estimation helps us to directly check the hypothesis made by Taylor who argues that in a low-inflation environment firms expect a deviation of inflation to be less persistent and would therefore less adjust its selling prices in response to an exchange rate-induced increase in the price of imported inputs.

Figures 4 and 5 display the response of the three indexes to an exchange rate shock for inflation targeting countries and non targeting countries, respectively⁶. Figure 4 reports before-and-after comparisons for inflation targeters before and after adopting inflation targeting. Figure 5 reports before-and-after comparisons for inflation nontargeters before and after 1999. In addition, figure 6 reports comparisons across the two samples of countries : inflation targeters after adopting inflation targeting are compared to nontargeters after 1999.

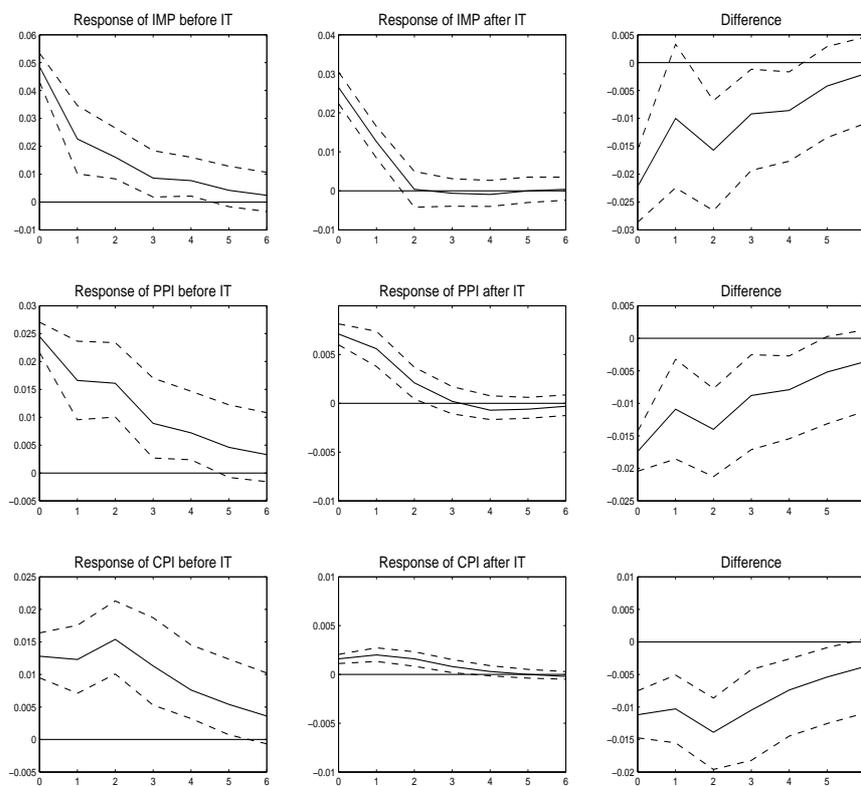

Figure 4 shows that the decline in pass-through to consumer prices in emerging inflation targeters is attributable to the decline in pass-through effect along the price chain. The pass-through effects to all the three prices significantly falls in emerging inflation targeters after adopting inflation targeting to levels that are significantly different from zero.

Figure 5 shows that the increase in pass-through to consumer prices in emerging nontargeters after 1999 results from the increase in pass-through to import prices. As shown in Figure 5, before 1999, pass-through to prices in nontargeters are not significantly different from zero. While after 1999 pass-through to prices in nontargeters are significantly positive. This result (by comparing to that result in 5-variable VAR) can be interpreted as the fact that the significant increase in the pass-through to consumer prices in nontargeters after 1999 reflects the increase in the pass-through to import and producer prices in nontargeters after 1999.

Figure 6 compares the exchange rate pass-through to prices in targeters after inflation targeting to those in nontargeters after 1999. The impulse responses function in Figure 6 indicate that the exchange pass-through to import and producer prices in inflation targeting countries after the adoption of this monetary strategy is significantly higher than that in nontargeters after 1999, while the exchange pass-through to consumer prices in targeters after inflation targeting is not significantly different than that in nontargeters

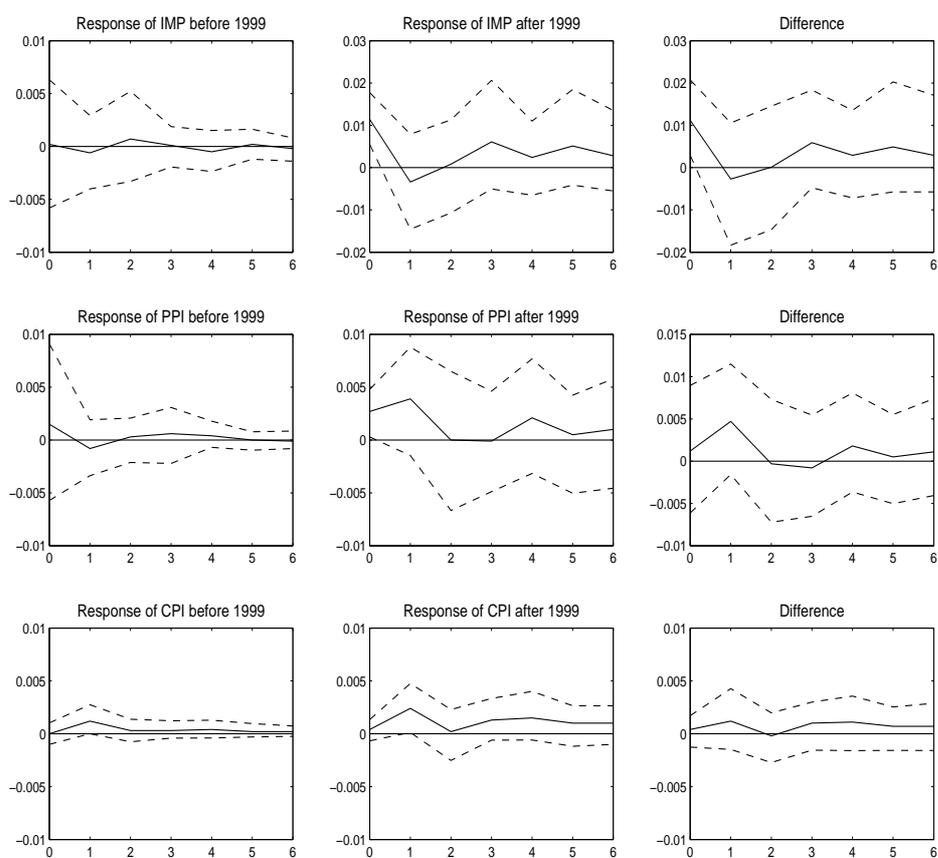

6. For nontargeters sample, China and Uruguay are not included in the 7-variable VAR. We have not data on import and producer prices for China and we have not data on producer prices for Uruguay.

FIGURE 4 – Response of prices in emerging targeters to an exchange rate shock (7-variable VAR)

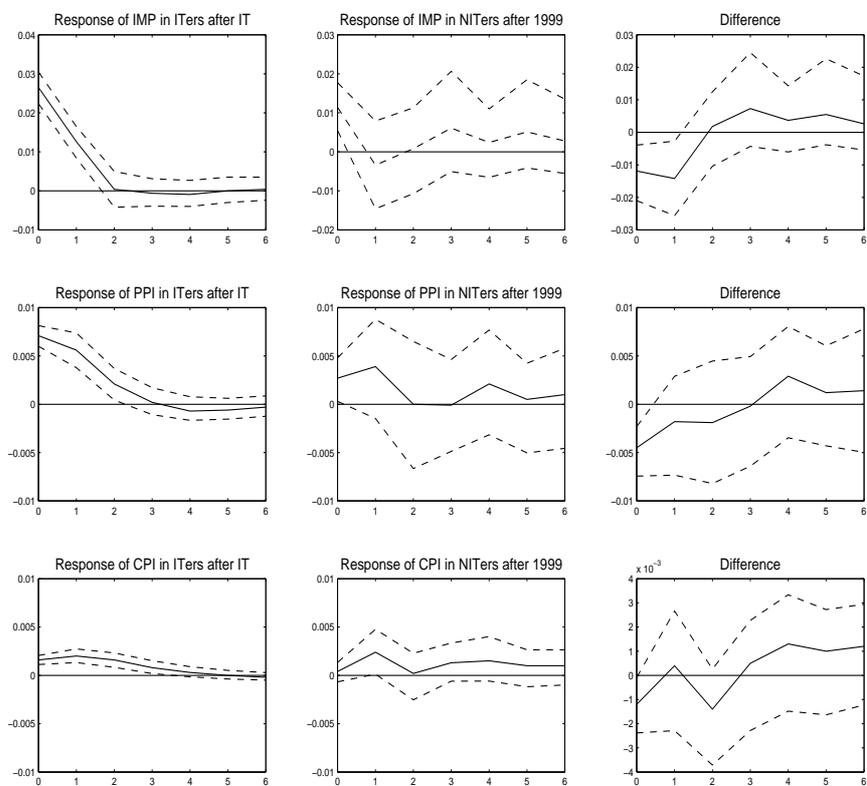

Note : The solid line shows the impulse response to an exchange rate shock. The dashed lines indicate five standard error confidence band around the estimate. Error are generated by Monte-Carlo with 500 repetitions.

FIGURE 5 – Response of prices in emerging nontargeters to an exchange rate shock (7-variable VAR)

Note : The solid line shows the impulse response to an exchange rate shock. The dashed lines indicate five standard error confidence band around the estimate. Error are generated by Monte-Carlo with 500 repetitions.

FIGURE 6 – Response of prices to an exchange rate shock : targeters versus nontargeters (7-variable VAR)

Note : The solid line shows the impulse response to an exchange rate shock. The dashed lines indicate five standard error confidence band around the estimate. Error are generated by Monte-Carlo with 500 repetitions.

after 1999.

By comparing the exchange rate pass-through along the price chain, the results show that the response is the largest in import prices, then in producer prices, and the least in consumer prices. This finding is consistent with those of previous results such as McCarthy (2000), Hahn (2003), Faruque (2006) and Ito and Sato (2007, 2008).

In summary, we have obtained evidence that the adoption of inflation targeting has helped to reduce the pass-through to all three price indexes from a higher level to a new level that remains significantly different from zero. By comparing targeters after the adoption of inflation targeting to nontargeters after 1999, our evidence suggests that exchange rate pass-through to import and producer prices in targeters after adoption is significantly higher than that in nontargeters after 1999, while the exchange rate pass-through to consumer prices in targeters after adoption is not significantly different than that in nontargeters after 1999.

Our evidence confirms the view that when initial credibility of emerging markets' central banks is low, practicing inflation targeting makes their monetary policy more credible, and thus leads to a lower inflation environment. More specifically, in accordance with the argument made by Taylor, inflation targeting by implementing low inflation environment in emerging countries induces input-importing firms as well as retailing firms to pass through less of the exchange rate depreciation in the form of higher prices (producer prices and import prices). Hence exchange rate fluctuations lead to smaller exchange rate pass-through to domestic producer and import prices.

3.3 Variance decomposition

Even though impulse responses give information about the size of exchange rate pass-through to domestic prices, they do not show how important exchange rate shocks are in explaining domestic price fluctuations. To assess the importance of exchange rate shocks for domestic prices fluctuations, we perform a variance decomposition of domestic prices. We begin by examining the importance of exchange rate shocks for consumer prices by using the 5-variable VAR (Table 2). Table 2 indicates that exchange rate shocks are more important in explaining consumer prices fluctuations in targeters countries. The results contained in Table 2 also show that the contribution of exchange rate shocks to consumer prices fluctuation decreases in targeting countries after they adopted inflation targeting, while it increases in nontargeting countries after 1999. Exchange rate shocks explain (after 20 quarters) 19.40% of consumer prices forecast variance for targeting countries before they adopted inflation targeting. This percentage declines to 11.03% after

the adoption of inflation targeting. In nontargeting countries, exchange rate shocks explain (after 20 quarters) 0.92% of consumer prices variability before 1999, and, this percentage increases to 6.39% after 1999.

TABLE 2 – Percentage of consumer prices forecast variance attributed to exchange rate shocks (5-variable VAR)

Horizon	Emerging targeters		Emerging nontargeters	
	Before IT	After IT	Before 1999	After 1999
1	9.52	5.47	0.00	3.69
2	15.36	10.42	1.01	6.78
4	22.78	12.28	0.88	6.39
8	20.39	11.33	0.89	6.50
12	19.55	11.11	0.91	6.40
20	19.40	11.03	0.92	6.39

Table 3 displays the contribution of exchange rate shocks in explaining the fluctuations of all three price indexes using the 7-variable VAR. The results in Table 3 indicate that exchange rate shocks are more important to explain the fluctuations of all three indexes in targeters countries, while the contribution of exchange rate shock to the fluctuations in price indexes in nontargeters countries is insignificant. The percentage of price forecast variance attributed to exchange rate shocks declines in targeting countries after they adopted inflation targeting, while it slightly increases in nontargeters after 1999. In targeters before they adopted inflation targeting exchange shocks explain (after 20 quarters) 39.76%, 36.92% and 19.18% of the variance of import prices, producer prices and consumer prices, respectively. After the adoption of inflation targeting, these percentages fall to 15.57%, 22.30% and 13.62%, respectively. In nontargeters before 1999, exchange rate shocks explain (after 20 quarters) 0.05%, 0.08% and 1.09% of the variance of import prices, producer prices and consumer prices, respectively. After 1999, these contributions are 2.40%, 2.42% and 2.94%, respectively.

In summary, the variance decomposition analysis indicates that exchange rate shocks explain an important part of prices fluctuations in targeters countries, while the contribution of exchange rate shocks to the fluctuations in prices in nontargeters countries is insignificant. The variance decomposition analysis also shows that the contribution of exchange rate shocks to prices fluctuations in targeting countries declines after the adoption of inflation targeting. Hence the variance decomposition analysis corroborates the decline in exchange rate pass-through in targeting countries after adopting inflation targeting.

TABLE 3 – Percentage of prices forecast variance attributed to exchange rate shocks in emerging targeters (7-variable VAR)

Horizon	Emerging targeters		Emerging nontargeters	
	Before IT	After IT	Before 1999	After 1999

4 Conclusion

In this paper, we have empirically examined the effect of the adoption of an inflation targeting strategy on the exchange rate pass-through to prices in emerging countries. To conduct this empirical study, we used panel VAR techniques using data on twenty-seven emerging countries (fifteen inflation targeters and twelve inflation nontargeters). To test for differences, we have adopted the difference-in-difference approach by comparing impulse response functions in different country samples, depending on the adoption of inflation targeting.

The adoption of inflation targeting modifies the pricing decisions in emerging countries in a way which is consistent with the credibility view. The adoption of inflation targeting has helped to reduce the pass-through to all

three price indexes that we considered (import prices, producer prices and consumer prices) in targeting countries from a higher level to a new level that remains significantly different from zero. For nontargeters countries exchange pass-through to all three price indexes is not significantly different zero before 1999, while after 1999 exchange rate pass-through to all the three prices is significantly different from zero. By comparing targeters after inflation targeting to nontargeters after 1999, our evidence suggests that exchange rate pass-through to import and producer prices in targeters after inflation targeting is significantly higher than that in nontargeters after 1999, while the exchange pass-through to consumer prices in targeters after inflation targeting is not significantly different to that in nontargeters after 1999. The variance decomposition corroborates these results. The variance decomposition analysis indicates that the contribution of exchange rate shocks to prices fluctuations in targeters countries is important, while the contribution of exchange rate shocks to prices fluctuations in nontargeters countries is insignificant. The variance decomposition analysis also shows that the contribution of exchange rate shocks to prices fluctuations in targeters countries declines after the adoption of inflation targeting.

Finally, our evidence suggests that countries experiencing high exchange rate pass-through were more prone to adopt inflation targeting in order to gain credibility, than countries with low pass-through.

Appendix

.1 Countries in the sample

Emerging inflation targeters and adoption date of inflation targeting :

Brazil (1999 :Q2), Chile (1991 :Q1), Colombia (1999 :Q4), Czech Republic (1997 :Q4), Hungary (2001 :Q2), Indonesia (2005 :Q3), Israel (1991 :Q4), Mexico (1998 :Q4), Peru (1999 :Q3), Philippines (1999 :Q3), Poland (1998 :Q3), South Africa (2001 :Q1), South Korea (1997 :Q4), Thailand (2000 :Q2), Turkey (2006 :Q1).

Emerging inflation nontargeters : Argentina, Bulgaria, China, Estonia, India, Latvia, Lithuania, Malaysia, Singapore, Taiwan, Uruguay, Venezuela.

.2 Variable and their sources

The world oil price : The US dollar-basis oil price index that is an average of the three spot price index of Texas, U.K. Brent and Dubai. The world oil price is seasonally adjusted using the Census X12 method. Data source : IMF, International Financial Statistics (henceforth, IFS).

The output gap : The output gap is generated by applying the Hodrick-Prescott (HP) filter to eliminate a strong trend in the seasonally adjusted real gross domestic product (GDP). If the original GDP series is not adjusted, series is seasonally adjusted using the Census X-12 method. The quarterly data are collected using Datastream. The data sources depending on the countries are the following :

Argentina : GDP volume index (2000=100), IMF's International Financial Statistics (IFS)

Brazil : GDP volume index (1995=100) (seasonally adjusted), Instituto Brasileiro de Geografia e Estatística (IBGE) (Brazil).

Bulgaria : GDP volume index, IFS.

Chile : GDP at 2003 prices (seasonally adjusted) Banco Central de Chile

China : GDP at current price (from IFS) divided by CPI.

Colombia : GDP at 2000 prices (seasonally adjusted), National Administrative Department of Statistics (Colombia).

Czech Republic : GDP at 2000 prices, (seasonally adjusted), Organization of Economic Co-operation and Development (OECD).

Estonia : GDP at 2000 prices, Estonia Statistics (Estonia).

Hungary : GDP volume index (2000=100)(seasonally adjusted),OECD.
 India : GDP Volume index (2005=100) (seasonally adjusted), OECD.
 Indonesia : GDP at 2000 prices (seasonally adjusted), OECD.
 Israel : GDP at 2005 prices (adjusted series), Central Bureau of Statistics (Israel).
 Latvia : GDP at 2000 prices, Central Statistics Bureau of Latvia (Latvia).
 Lithuania : GDP at 2000 prices (seasonally adjusted), Statistics Lithuania (Lithuania).
 Malaysia :GDP volume index (2000=100), IFS.
 Mexico : GDP volume index (2000=100), IFS.
 Peru : GDP volume index (2000=100), IFS.
 Philippines : GDP at 1985 prices (seasonally adjusted), National Statistical Coordination Board (NSCB) (Philippines).
 Poland : GDP at 2000 prices (seasonally adjusted),OECD.
 Singapore : GDP volume index (2000=100), IFS.
 South Africa : GDP at 2000 prices, (seasonally adjusted),IFS.
 South Korea : GDP at 2000 prices (seasonally adjusted),OECD, (Quarterly National Accounts).
 Taiwan : GDP at 2001 prices, Directorate General of Budget, Accounting and Statistics (DGBAS).
 Thailand : GDP at 1988 prices (seasonally adjusted), Office of National Economic and Social Development Board (Thailand).
 Turkey : GDP at 1995 prices, Eurostat.
 Uruguay : GDP volume index (2005=100) (seasonally adjusted), Banco Central de Uruguay (Uruguay).
 Venezuela : GDP at 1997 prices (seasonally adjusted), Banco Central de Venezuela (Venezuela).

Money supply : The data is collected using Datastream. For some countries, base money is used. For others, M1 is used. If the original series is not adjusted, series is seasonally adjusted using the Census X-12 method. The data sources depending on countries are the following :

Argentina : Base money,IFS.
 Brazil : Base money, (seasonally adjusted), IFS.
 Bulgaria : Money M1 (Banking Survey), IFS.
 Chile : Money M1, IFS.
 China : Money Supply, People Bank of China.
 Colombia : Money M1 (Banking Survey), IFS.
 Czech Republic : Money M1 (Banking Survey), IFS.

Estonia : Money M1 (Banking Survey),(seasonally adjusted), IFS.
 Hungary : Monetary Base, IFS.
 India : Money M1 (Banking Survey), IFS.
 Indonesia : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 Israel : Money M1 (seasonally adjusted), IFS.
 Latvia : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 Lithuania : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 Malaysia :Money M1, (seasonally adjusted), IFS.
 Mexico : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 Peru : Money supply, IFS.
 Philippines : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 Poland : Money M1, IMF, International Financial Statistics (IFS).
 Romania : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 Singapore : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 South Africa : Money M1, IFS.
 South Korea : Money M1 (seasonally adjusted), IFS.
 Taiwan : Money supply, Bank Central of China.
 Thailand : Money M1 (Banking Survey), IFS.
 Turkey : Money M1 (Banking Survey) (seasonally adjusted), IFS.
 Uruguay : Money M1 (Banking Survey)(seasonally adjusted), IFS.
 Venezuela : Money M1 (Banking Survey)(seasonally adjusted), IFS.

Exchange rate : The data is collected using Datastream. The period average bilateral nominal exchange rate vis-à-vis the US dollar are used. For all countries, expected Taiwan, the data is taken from IMF's IFS. For Taiwan the data is taken from IFO World Economic Survey (WES).

Consumer Prices Index : The data is collected using Datastream. For all countries expected China the consumer price index (2000=100) is taken from IMF, International Financial Statistics (IFS). For china, the monthly CPI taken from EOCED is used to construct the quarterly CPI. All series are seasonally adjusted using the Census X-12 method.

Import Prices Index : The data is collected using Datastream. The import prices index are expressed in home currency. All series are seasonally adjusted using the Census X-12 method. The data sources depending on countries are the following :

Argentina : The import price index is the import unit value in US dol-

lar (2000=100) taken from IFS multiplied by the exchange rate.

Brazil : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.

Bulgaria : The quarterly series of import price index is constructed by dividing the total import value by the total import volume (1995 prices). The import value and the import volume are taken from National Statistics Institute (Bulgaria) and Eurostat, respectively.

Chile : Import Price Index (2003=100), Banco Central de Chile (Chile).

Colombia : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.

Czech Republic : Import Price Index (2005=100), Czech Statistical of Office.

Estonia : The quarterly series of import price index is constructed by dividing the total import value by the total import volume (2000 prices) Statistics Estonia. The data are taken from Statistics Estonia (Estonia).

Hungary : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.

India : The quarterly series of import price index is constructed by dividing the total import value by the total import volume (1990 prices). Data are taken from OECD.

Indonesia : The quarterly series of import price index is constructed by dividing the total import value by the total import volume (2000 prices). Data are taken from EOCED.

Israel : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.

Latvia : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.

Lithuania : The quarterly series of import price index is constructed by dividing the total import value by the total import volume (2000 prices). The data are taken from Statistics Lithuania.

Malaysia : The quarterly series of import price index is constructed by dividing the total import value by the total import volume (2000 prices). The data are from Department of Statistics (Malaysia).

Mexico : The quarterly import price index is constructed by the monthly import price index (1980=100) taken from Banco de Mexico (Mexico).

Peru : The quarterly import price index is constructed by the average monthly import price index (1994=100) taken from Banco Central Reserva (Peru).

Philippines : The import price index is the import unit value in USdollar (2000=100) taken from IFS multiplied by the exchange rate.

Poland : The import price index is the import unit value in US dollar

(2000=100) taken from IFS multiplied by the exchange rate.
Singapore : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.
South Africa :The import price index is the import prices index in US dollar (2000=100) taken from IFS multiplied by the exchange rate.
South Korea : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.
Taiwan : The quarterly import price index is constructed by the average monthly import price index (manufactruing goods) (2001=100) taken from Directorate General of Budget, Accounting and Statistics (DGBAS).
Thailand :The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.
Turkey :The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.
Venezuela : The import price index is the import unit value in US dollar (2000=100) taken from IFS multiplied by the exchange rate.

Producer Prices Index : The data is collected using Datastream. For all countries expected Taiwan and Turkey, the producer prices index are taken form IFS. For Taiwan the quarterly producer prices index are the average monthly output prices index (2006=100) taken from Taiwans Directorate General of Budget, Accounting and Statistics. For Turkey the quarterly data are taken from Turkeys National Institute of Statistics.
