Abstract

We characterize all quasiperiodic Sturmian words: a Sturmian word is not quasiperiodic if and only if it is a Lyndon word. Moreover, we study links between Sturmian morphisms and quasiperiodicity.

Keywords: Sturmian words, quasiperiodicity, Lyndon words, morphisms

1 Introduction

The notion of repetition in Strings is central in a lot of researches, in particular in Combinatorics on Words and in Text Algorithms (see for instance [9], [10] for recent surveys). In this vein, Apostolico and Ehrenfeucht introduced the notion of quasiperiodic finite words [2] in the following way: “a string $w$ is quasiperiodic if there is a second string $u \neq w$ such that every position of $w$ falls within some occurrence of $u$ in $w$”. The reader can consult [1] for a short survey of studies concerning quasiperiodicity. In [12], Marcus extends this notion to right infinite words and he opens six questions. Four of them are answered in [7].

One of these six questions is: does there exist a non-quasiperiodic Sturmian word? In [7], we provide an example of such a word, but this positive answer is not completely satisfying. Since a first feeling can be that there exists no (or at most very few) such word, one can ask for a complete characterization of such non-quasiperiodic Sturmian words. After some preliminaries in Sections 2, 3 and 4, we provide two answers described below.

Sturmian words have been widely studied because of their many beautiful properties and links with many fields (see [9] Chapter 2 for a recent survey). One aspect of these words is that they can be infinitely decomposed over the four morphisms $L_a$, $L_b$, $R_a$ and $R_b$ (see Section 3 for more details). The first characterization of non-quasiperiodic Sturmian words proposed in this paper is based on such a decomposition. More precisely, Theorem 5.6 states that a Sturmian word is not quasiperiodic if and only if it can be decomposed infinitely over $\{L_a, R_b\}$ or infinitely over $\{L_b, R_a\}$.

Our second characterization (Theorem 6.5) provides a more semantic answer: a Sturmian word is not quasiperiodic if and only if it is an infinite Lyndon word.

The proof of our first result uses the fact that some morphisms obtained by compositions of the morphisms $L_a$, $L_b$, $R_a$ and $R_b$ map any infinite words into a quasiperiodic one. We call such a morphism strongly quasiperiodic. In Section 7, we characterize the Sturmian morphisms which are...
2 Generalities

We assume the reader is familiar with combinatorics on words and morphisms (see, e.g., \[8, 9\]). We precise our notations.

Given a set $X$ of words (for instance an alphabet $A$, that is a non-empty finite set of letters), $X^*$ (resp. $X^\omega$) is the set of all finite (resp. infinite) words that can be obtained by concatenating words of $X$. The empty word $\varepsilon$ belongs to $X^*$. The length of a word $w$ is denoted by $|w|$. By $|w|_a$ we denote the number of occurrences of the letter $a$ in $w$. A finite word $w$ is a factor of a finite or infinite word $w$ if there exist words $p$ and $s$ such that $w = pws$. If $p = \varepsilon$ (resp. $s = \varepsilon$), $u$ is a prefix (resp. suffix) of $w$. A word $u$ is a border of a word $w$ if $u$ is both a prefix and a suffix of $w$. A factor $u$ of a word $w$ is said proper if $w \neq u$.

Given an alphabet $A$, a(n endo)morphism $f$ on $A$ is an application from $A^*$ to $A^*$ such that $f(uv) = f(u)f(v)$ for any words $u, v$ over $A$. A morphism on $A$ is entirely defined by the images of letters of $A$. All morphisms considered in this paper will be non-erasing: the image of any non-empty word is never empty. The image of an infinite word is thus infinite and naturally obtained as the infinite concatenation of the images of the letters of the word. In what follows, we will denote the composition of morphisms by juxtaposition as for concatenation of words. Given a set $X$ of morphisms, we will also note $X^*$ the set of all finite compositions of morphisms of $X$ and $X^\omega$ the set of all infinite decompositions of morphisms of $X$. When a word $w$ is equal to $\lim_{n \to \infty} f_1f_2 \ldots f_n(a)$, $f_i \in X$, we will say that $w$ can be decomposed (infinitely) over $X$.

Given a morphism $f$, powers of $f$ are defined inductively by $f^0 = \text{Id}$ (the Identity morphism), $f^i = ff^{i-1}$ for integers $i \geq 1$. When for a letter $a$, $f(a) = ax$ with $x \neq \varepsilon$, the morphism $f$ is said prolongable on $a$. In this case, for all $n \geq 0$, $f^n(a)$ is a prefix of $f^{n+1}(a)$. If moreover, for all $n \geq 0$, $|f^n(a)| < |f^{n+1}(a)|$, the limit $\lim_{n \to \infty} f^n(a)$ is the infinite word denoted $f^\omega(a)$ having all the $f^n(a)$ as prefixes. This limit is also a fixed point of $f$.

3 Sturmian words and morphisms

Sturmian words may be defined in many equivalent ways (see \[8, \text{chapter 2}\] for instance). They are infinite binary words. Here we first consider them as the infinite balanced non ultimately periodic words. We recall that a (finite or infinite) word $w$ over $\{a, b\}$ is balanced if for any factors $u$ and $v$ of same length $|u|_a - |v|_a| \leq 1$, and that an infinite word $w$ is ultimately periodic if $w = uv^\omega$ for some finite words $u$ and $v$.

Many studies of Sturmian words use Sturmian morphisms, that is morphisms that map any Sturmian word into a Sturmian word. Séebold \[17\] proved that the set of these morphisms is $\{E, L_a, L_b, R_a, R_b\}$ where $E, L_a, L_b, R_a, R_b$ are the morphisms defined by

$$E : \begin{cases} a \mapsto b, & b \mapsto a, \end{cases} \quad L_a : \begin{cases} a \mapsto a, & b \mapsto ab, \end{cases} \quad L_b : \begin{cases} a \mapsto ba, & b \mapsto b, \end{cases} \quad R_a : \begin{cases} a \mapsto a, & b \mapsto ba, \end{cases} \quad R_b : \begin{cases} a \mapsto ab, & b \mapsto b. \end{cases}$$

Many relations exist between Sturmian words and Sturmian morphisms. For instance, recently the following result was proved:
Theorem 3.1 \([\mathbb{R}]\) Any Sturmian word \(w\) over \(\{a, b\}\) admits a unique representation of the form

\[
w = \lim_{n \to \infty} L_a^{d_1} R_a^{c_1} L_b^{d_2} R_b^{c_2} \ldots L_a^{d_{2n-1}} R_a^{c_{2n-1}} L_b^{d_{2n}} R_b^{c_{2n}}(a)
\]

where \(d_k \geq c_k \geq 0\) for all integer \(k \geq 1\), \(d_k \geq 1\) for \(k \geq 2\) and if \(c_k = d_k\) then \(c_{k-1} = 0\).

Remark: Let us mention that this representation is not expressed as in \([\mathbb{R}]\) where it is written

\[
w = T^{c_1} L_a^{d_1} T^{c_2} L_b^{d_2} T^{c_3} L_a^{d_3} T^{c_4} L_b^{d_4} \ldots
\]

where \(T\) is the shift map defined, for any infinite word \((a_n)_{n \geq 0}\) with \(a_n\) letter for any \(n \geq 0\), by \(T(a_n)_{n \geq 0} = (a_{n+1})_{n \geq 0}\). One can verify that for integers \(c, d\) such that \(d \geq c \geq 0\) and for any infinite word \(w\), \(T^c L_a^d(w) = L_a^{d-c} R_a^c(w)\) and \(T^c L_b^d(w) = L_b^{d-c} R_b^c(w)\). This explains the links between the two representations. The interested reader will also find relations between this representation and the notion of S-adic systems defined by Ferenczi \([\mathbb{R}]\) as minimal dynamical systems generated by a finite number of substitutions.

A particular well-known family of Sturmian words is the set of standard (or characteristic) Sturmian words. It corresponds to the case where for each \(k \geq 0\), \(c_k = 0\). Hence any standard Sturmian word admits a unique representation on the form:

\[
w = \lim_{n \to \infty} L_a^{d_1} R_a^{c_1} L_b^{d_2} R_b^{c_2} \ldots L_a^{d_{2n-1}} R_a^{c_{2n-1}} L_b^{d_{2n}}(a)
\]

where \(d_1 \geq 0\) and \(d_k \geq 1\) for all \(k \geq 2\).

To end this section, we recall useful relations between Sturmian morphisms.

Theorem 3.2 \([\mathbb{R}]\) (see also \([\mathbb{R}]\) for a generalization) The monoid \(\{L_a, L_b, R_a, R_b, E\}^\star\) of Sturmian morphisms has the following presentation:

\[
(1) \quad EE = Id,
(2) \quad EL_a = L_bE \text{ and } ER_a = R_bE,
(3) \quad L_a L_b^n R_a = R_b R_a^n L_a, \text{ for any } n \geq 0.
\]

Note that from (2) and (3), we get: \(L_b L_b^n R_b = R_b R_a^n L_b\) for any \(n \geq 0\).

4 Word quasiperiodicity and morphisms

In this paper, we consider mainly infinite quasiperiodic words. However we first recall the notion of finite quasiperiodic words to allow us some comparisons.

We consider definitions from \([\mathbb{R}]\). A word \(u\) covers another word \(w\) if for every \(i \in \{1, \ldots, |w|\}\), there exists \(j \in \{1, \ldots, |z|\}\) such that there is an occurrence of \(u\) starting at position \(i - j + 1\) in the word \(w\). When \(u \neq w\), we say that \(u\) is a quasiperiod of \(w\) and that \(w\) is quasiperiodic. A word is superprimitive if it is not quasiperiodic (Marcus \([\mathbb{R}]\) calls minimal such words). One can observe that any word of length 1 is not quasiperiodic. The word

\[
w = abaababaabaababaaba
\]

has \(aba, abaaba, abaababaaba\) as quasiperiods. Only \(aba\) is superprimitive. More generally in \([\mathbb{R}]\), it is proved that any quasiperiodic finite word has exactly one superprimitive quasiperiod. This is a consequence of the fact that any quasiperiod of a finite word \(w\) is a proper border of \(w\).
When defining infinite quasiperiodic words, instead of considering the starting indices of the occurrences of a quasiperiod, for convenience, we choose to consider the words preceding the occurrences of a quasiperiod. An infinite word \( w \) is quasiperiodic if there exist a finite word \( u \) and words \((p_n)_{n \geq 0}\) such that \( p_0 = \varepsilon \) and, for \( n \geq 0 \), \( 0 < |p_{n+1}| - |p_n| \leq |u| \) and \( p_n u \) is a prefix of \( w \). We say that \( u \) covers \( w \), or that \( w \) is \( u \)-quasiperiodic. The word \( u \) is also called a quasiperiod and we say that the sequence \((p_n u)_{n \geq 0}\) is a covering sequence of prefixes of the word \( w \). The reader will find several examples of infinite quasiperiodic words in [11, 7]. Let us mention for instance that the well-known Fibonacci word, the fixed point of the morphism \( \phi : a \mapsto \rightarrow ab, b \mapsto \rightarrow a \), is \( aba \)-quasiperodic.

It is interesting to note that \( \phi^\omega(a) \) has an infinity of superprimitive quasiperiods (see [7] for a characterization of all quasiperiods of \( \phi^\omega(a) \)). This shows a great difference between quasiperiodic finite words and quasiperiodic infinite words. The reader can also note that for any positive integer \( n \), there exists an infinite word having exactly \( n \) quasiperiods (as for example the word \((ab)^n a(ab)^\omega)\), or having exactly \( n \) superprimitive quasiperiods [7].

To end this section, let us observe that any quasiperiod of a (finite or infinite) quasiperiodic word \( w \) is a prefix of \( w \). Hence \( w \) has a unique quasiperiod of smallest length that we call the smallest quasiperiod of \( w \). When \( w \) is finite, the smallest quasiperiod of \( w \) is necessarily its superprimitive quasiperiod. When \( w \) is infinite, its smallest quasiperiod is also superprimitive, but there can exist other superprimitive quasiperiods (see above).

Moreover:

**Lemma 4.1** If \( w \) is an infinite quasiperiodic word with smallest quasiperiod \( u \), then \( uu \) is a factor of \( w \).

**Proof.** If \( uu \) is not a factor of \( w \) then the prefix \( v \) of \( u \) of length \( |u| - 1 \) is a quasiperiod of \( w \). This is not possible if \( u \) is the smallest quasiperiod.

Let us observe that Lemma 4.1 is not true for finite words as shown by the \( aba \)-quasiperiodic word \( ababa \).

In the following we will also use the immediate following fact:

**Fact 4.2** If \( w \) is a (finite or infinite) \( u \)-quasiperiodic word and \( f \) is a non-erasing morphism, then \( f(w) \) is \( f(u) \)-quasiperiodic.

5 Sturmian non-quasiperiodic words

In this section, we prove our main result (Theorem 5.6) which is a characterization of all non-quasiperiodic Sturmian words. Before this, we prove several useful results.

Let \( w \) be a Sturmian word. Denoting by \( n \) the least number of \( a \) between two consecutive \( b \) in \( w \) and by \( i \) the initial number of \( a \) in \( w \), we can deduce from the balance property of \( w \) that \( w \) belongs to \( a^i ba^n, ba^{n+1}\). When \( 0 < i \leq n \), \( w \) belongs to \( \{a^ib a^n, a^i ba^{n+1-i}\} \) and \( w \) is \( a^ib a^{n+1} \)-quasiperiodic (and \( a^ib a^{n-i+1} \) is the smallest quasiperiod of \( w \)). Thus:

**Fact 5.1** If \( w \) is a non-quasiperiodic Sturmian word, then there exists an integer \( n \) such that \( w \) belongs to \( a^{n+1} b(a^n b, a^n b + 1) \) \( \omega \) \( \{ba^n, ba^{n+1}\} \) \( \omega \).

4/15
Of course some Sturmian words in $a^{n+1}b\{a^n, b^{n+1}\}^\omega \cup \{ba^n, ba^{n+1}\}^\omega$ are quasiperiodic: it is the case of the image of any quasiperiodic Sturmian word starting with $a$ by the Sturmian morphism $L^p \circ R_b^p: a \mapsto a^{n+1}b, b \mapsto a^n b$.

A consequence of Fact 5.1 is:

**Lemma 5.2** For all Sturmian word $w$ and $x \in \{a, b\}$, $L_x R_x(w) = R_x L_x(w)$ is quasiperiodic.

**Proof.** Without loss of generality, assume $x = a$. From Theorem 1.2, $L_a R_a = R_a L_a$. Let us recall that $L_a R_a(a) = a$ and $L_a R_a(b) = aba$. From Fact 1.2, if $w$ is a quasiperiodic word, then $L_a R_a(w)$ is quasiperiodic. Assume now that $w$ is a Sturmian non-quasiperiodic word. By Fact 5.1, $w$ belongs to $a^{n+1}b\{a^n, b^{n+1}\}^\omega \cup \{ba^n, ba^{n+1}\}^\omega$ for an integer $n$. Hence $L_a R_a(w)$ belongs to one of the sets $a^{n+1}aba \{a^nb, a^{n+1}a\}$ or $\{baa^n, abaa^{n+1}\}^\omega$. So $L_a R_a(w)$ is $a^{n+2}ba$-quasiperiodic or $a^{n+2}$-quasiperiodic.

Let us observe that $ba^\omega$ and $L_a R_a(ba^\omega) = aba^\omega$ are not quasiperiodic. This shows that Lemma 5.2 is not true for arbitrary words (even if they are balanced), unlike the next fact which is a direct consequence of the definition of $L_a L_b$: $a \mapsto aba, b \mapsto ab$, and $L_a L_a: a \mapsto ba, b \mapsto bab$.

**Fact 5.3** For any infinite word $w$, $L_a L_b(w)$ is $aba$-quasiperiodic and $L_b L_a(w)$ is $bab$-quasiperiodic.

Lemma 5.2 and Fact 5.3 will be useful to prove that our condition in Theorem 5.6 is necessary. To show it is sufficient, we now consider situations where the image of a word by a Sturmian morphism is not necessarily quasiperiodic.

**Lemma 5.4** Let $x \in \{a, b\}$ and let $w$ be a balanced word starting with $x$. The word $L_x(w)$ is quasiperiodic if and only if $w$ is quasiperiodic. Moreover in this case, the smallest quasiperiod of $L_x(w)$ is the word $L_y(w)$ where $v$ is the smallest quasiperiod of $w$.

**Proof.** Without loss of generality, we consider here that $x = a$.

From Fact 4.2, if $w$ is quasiperiodic then $L_a(w)$ is quasiperiodic.

From now on we assume that $L_a(w)$ is $u$-quasiperiodic where $u$ is the smallest quasiperiod of $L_a(w)$. If $w$ has at most one occurrence of $b$, then $w = a^\omega$ or $w = a^n ba^\omega$ for an integer $n \geq 0$.

Since $L_a(w)$ is quasiperiodic, we have $w = a^\sigma$ and we verify that the smallest quasiperiod of $w$ and $L_a(w)$ is $a = L_a(a)$. From now on we assume that $w$ contains at least two occurrences of the letter $b$. Denoting by $n$ the least number of $a$ between two consecutive occurrences of $b$ in $w$ and by $i$ the number of $a$ before the first $b$, since $w$ is balanced, $w \in a^i \{ba^n, ba^{n+1}\}^\omega$ and $0 \leq i \leq n + 1$.

If $0 < i \leq n$, then $w$ and $L_a(w)$ are quasiperiodic with respective smallest quasiperiod $a^i ba^{n-i+1}$ and $a^{n+1}ba^{-(n+i)} = L_a(a^{i}ba^{n-i+1})$.

By hypothesis, $w$ starts with $a$, so we cannot have $i = 0$.

In the case $i = n + 1$: $w \in a^{n+1}b\{a^n, b^{n+1}\}^\omega$ and $L_a(w) \in a^{n+2}(ba^{n+1}, ba^{n+2})^\omega$. Since $u$ is a quasiperiod of $L_a(w)$, $u$ is a prefix of $L_a(w)$ and starts with $a^{n+2}b$. By Lemma 1.1, $uu$ is a factor of $L_a(w)$. It follows that $u$ ends with $b$ and $u = L_a(v)$ for a word $v \in \{a^n b, a^{n+1}b\}^*$. Now we prove that $v$ is a quasiperiod of $w$. Let $(p_k u)_{k \geq 0}$ be a covering sequence of $L_a(w)$ ($p_0 = \varepsilon$ and for all $k \geq 0, p_k u$ is a prefix of $L_a(w)$ and $|p_{k+1}| - |p_k| \leq |u|$). Since $w$ starts with $a^{n+2}b$, for each $k \geq 0$, there exists a word $p_k'$ such that $p_k = L_a(p_k')$. Of course, $p_0 = \varepsilon$. Since $v \in \{a^n b, a^{n+1}b\}^*$, we can deduce for each $k \geq 0$ that $p_k'$ is a prefix of $w$. If for a $k$, $|p_{k+1} - |p_k'| > |v|$, then $p_{k+1}' = p_k'vy$ for a word $y$ and consequently $p_{k+1} = p_k u L_a(y)$ which contradicts the fact that $|p_{k+1} - |p_k| \leq |u|$.

5/15
for each $k \geq 0$, $|p_{k+1}'| - |p_k'| \leq |v|$. We have shown that $(p_{k}'v)_{k\geq 0}$ is a covering sequence of $w$, so $v$ is a quasiperiod of $w$. Assume $w$ has a quasiperiod $v'$ strictly smaller than $v$. Both $v$ and $v'$ are prefixes of $w$, so $v = v'$ for a non-empty word $s$. Then $|L_a(v')| = |L_a(v)| - |L_a(s)| < |L_a(v)|$ and $L_a(v')$ is a quasiperiod of $L_a(w)$ strictly smaller than $u = L_a(v)$. This contradicts the definition of $u$, so $v$ is the smallest quasiperiod of $w$.

\[ \square \]

**Lemma 5.5** Let $x, y$ be letters such that $\{x, y\} = \{a, b\}$ and let $w$ be a word starting with $x$. The word $R_y(w)$ is quasiperiodic if and only if $w$ is quasiperiodic. Moreover when these words are quasiperiodic, the smallest quasiperiod of $R_y(w)$ is the word $R_y(v)$ where $v$ is the smallest quasiperiod of $w$.

**Proof.** Without loss of generality, we consider here that $x = a$ and $y = b$.

From Fact 4.2, if $w$ is quasiperiodic then $R_y(w)$ is quasiperiodic. Assume now that $R_y(w)$ is quasiperiodic and let $u$ be its smallest quasiperiod. By hypothesis, $w$ starts with $a$, so does $u$. Since $aa$ is not a factor of $R_y(w)$ whereas by Lemma 4.1 $uu$ is a factor of $R_y(w)$, we deduce that $u$ ends with $b$. Thus there exists a word $v$ such that $u = R_y(v)$. As done in the proof of Lemma 5.4 for the case $w \in a^{n+1}\{ba^n, ba^{n+1}\}^\omega$, we can show that $v$ is a quasiperiod of $u$ and more precisely that it is its smallest quasiperiod. \[ \square \]

The reader can observe one difference between the two previous lemmas: Lemma 5.4 considers only balanced words when Lemma 5.5 works with arbitrary words (starting with $x$). Note that Lemma 5.4 becomes false if we do not consider balanced words. Indeed the word $w = abab(aaab)^\omega$ is not quasiperiodic, whereas $L_a(w) = aabaabaa(abaa)^\omega$ is $abaa$-quasiperiodic. The two lemmas become also false if we consider Sturmian words starting with $y$ where $\{x, y\} = \{a, b\}$. Indeed, let us consider the case $x = a, y = b$: it is known that the word $w = (L_bR_a)^\omega(a)$ is not quasiperiodic; this Sturmian word starts with $b$ and the word $L_a(w)$ (resp. $R_b(w)$) is aba-quasiperiodic (resp. bab-quasiperiodic).

We can now establish the announced characterization of non-quasiperiodic Sturmian words.

**Theorem 5.6** A Sturmian word $w$ is not quasiperiodic if and only if it can be infinitely decomposed over $\{L_a, R_b\}$ or over $\{L_b, R_a\}$. In other words a Sturmian word $w$ is not quasiperiodic if and only if

$$w = \lim_{n \rightarrow \infty} L_a^{d_1} R_b^{d_2} L_a^{d_3} R_b^{d_4} \ldots L_a^{d_{2n-1}} R_b^{d_{2n}}(a)$$

or

$$w = \lim_{n \rightarrow \infty} L_b^{d_1} R_a^{d_2} L_b^{d_3} R_a^{d_4} \ldots L_b^{d_{2n-1}} R_a^{d_{2n}}(a)$$

where $d_k \geq 1$ for all $k \geq 2$ and $d_1 \geq 0$.

**Proof.** We first show that the condition is necessary. Let $w$ be a non-quasiperiodic Sturmian word. By Theorem 3.1

$$w = \lim_{n \rightarrow \infty} L_a^{d_1-c_1} R_a^{c_1} L_b^{d_2-c_2} R_b^{c_2} \ldots L_a^{d_{2n-1}-c_2n-1} R_a^{c_2n-1} L_b^{d_{2n}-c_2n} R_b^{c_2n}(a)$$

where $d_k \geq c_k \geq 0$ for all integer $k \geq 1$, $d_k \geq 1$ for $k \geq 2$ and if $c_k = d_k$ then $c_{k-1} = 0$.

By Lemma 4.2, for $x \in \{a, b\}$ and any Sturmian word, $L_x R_x(w)$ is quasiperiodic. By Fact 4.2, this implies that for all $k \geq 1$, $c_k = d_k$ or $c_k = 0$.  

6/15
Assume that \( c_k = 0 \) and \( c_{k+1} = 0 \) for an integer \( k \geq 1 \). Then \( w = fL_aL_b(w') \) or \( w = fL_bL_a(w') \) for a Sturmian word \( w' \) and a morphism \( f \). By Fact 5.3, \( w \) is quasiperiodic. So for each \( k \geq 1 \), \( c_k = 0 \) implies \( c_{k+1} = d_{k+1} \).

We know that for each \( k \geq 2, c_k = d_k \) implies \( c_{k-1} = 0 \). This is equivalent to say that for each \( k \geq 1, c_k \neq 0 \) implies \( c_{k+1} \neq d_{k+1} \). But there for each \( k \), \( c_k = d_k \) or \( c_k = 0 \). Thus \( c_k = d_k \) implies \( c_{k+1} = 0 \), the condition is necessary.

Let us now show that any Sturmian word \( w \) that can be decomposed infinitely over \{\( L_a, R_b \)\} is not quasiperiodic (case \{\( L_b, R_a \)\} is similar). Assume by contradiction that it is not the case. Let \( S \) be the set of all Sturmian words \( w \) that can be decomposed over \{\( L_a, R_b \)\} and that are quasiperiodic. Let \( u \) be a quasiperiod of smallest length among all quasiperiods of words in \( S \), and let \( w \) be an element of \( S \) having \( u \) as quasiperiod. By definition, \( w = L_a(w') \) or \( w = R_b(w') \) for a word \( w' \) in \( S \). Since \( d_3 \neq 0 \), \( w \) starts with the letter \( a \). By Lemmas 5.3 and 5.4, \( u = L_a(v) \) or \( u = R_b(v) \) where \( v \) is the smallest quasiperiod of \( w' \). Since \( a^\omega \) and \( b^\omega \) are not Sturmian words (they are balanced but not ultimately quasiperiodic), \(|v|_a \neq 0 \) and \(|v|_b \neq 0 \). Consequently \(|v| < |u| \). This contradicts the choice of \( u \). Hence \( S \) is empty.

Given a word \( u \), let us denote \( X(w) \) the set of infinite words having the same set of factors than \( w \): \( X(w) \) is invariant by the shift operator and is called the subshift associated with \( w \). When \( w \) is Sturmian, it is known (see [8]) that a word \( u' \) belonging to \( X(w) \) if and only if it is Sturmian and the associated sequence \((d_k)_{k \geq 0}\) in its decomposition of Theorem 3.1 is the same as the one involved in the decomposition of \( w \).

To end this section, we observe that any standard Sturmian word (that is a Sturmian word that can be decomposed using only \( L_a \) and \( L_b \) is necessarily quasiperiodic. This gives a new proof of a result by T. Monteil [13, 14]: any Sturmian subshift contains a quasiperiodic word (let us mention that the result of T. Monteil is more precisely: any Sturmian subshift contains a multiscaled quasiperiodic word, that is a word having an infinity of quasiperiods). The interested reader will find materials in Section 7 to show that any standard Sturmian word has an infinity of quasiperiods (see Lemma 7.2). Theorem 5.6 also shows that in any Sturmian subshift, there is a non-quasiperiodic word.

6 A connection with Lyndon words

The aim of this short section is to give another characterization of non-quasiperiodic Sturmian words related to Lyndon words (see Theorem 6.3 below).

Let us recall notions on finite \[8\] and infinite \[13\] Lyndon words. We call suffix of an infinite word \( w \) any word \( w' \) such that \( w = uw' \) for a given word \( u \). When \( u \neq \varepsilon \), we say that \( w' \) is a proper suffix of \( w \). This definition allows us to adopt the same definition for finite and infinite Lyndon word. Let \( \preceq \) be a total order on \( A \) (in what follows, \( \{ a \prec b \} \) denotes the alphabet \( \{ a, b \} \) with \( a \prec b \). This order can be extended into the lexicographic order on words over \( A \). A (finite or infinite) word over \( (A, \preceq) \) is a Lyndon word if and only if \( w \) is strictly smaller than all its proper suffixes. Any infinite Lyndon word has infinitely many prefixes that are (finite) Lyndon words (and so an infinite Lyndon word can be viewed as a limit of these prefixes). The following basic property of finite Lyndon words was pointed out by J.P. Duval (see Acknowledgments):

**Fact 6.1** Any finite Lyndon word is unbordered, that is the only borders of a Lyndon word \( w \) are \( \varepsilon \) and \( w \).
This allows us to state a relation between infinite Lyndon words and non-quasiperiodic infinite
words (cf Corollary 6.3).

**Fact 6.2** If \( w \) is an infinite \( u \)-quasiperiodic word, then any prefix of \( w \) of length at least \( |u| + 1 \) is not unbordered.

**Proof.** If \( p \) is a prefix of \( w \) of length at least \( |u| + 1 \), then \( p \) has for suffix a prefix \( s \) of \( u \) (of length at most \( |u| \)). Since \( u \) is a prefix of \( w \), \( u \) is also a prefix of \( p \), and so \( s \) is a border of \( p \). \( \square \)

**Corollary 6.3** Any Lyndon word is not quasiperiodic.

Our main Theorem 6.5 is a direct consequence of this corollary and the following characterization. Following [16] we say that a morphism \( f \) preserves (finite) Lyndon words if for any (finite) Lyndon word \( w \), \( f(w) \) is also a Lyndon word. We have:

**Proposition 6.4** [16] A Sturmian morphism \( f \) preserves Lyndon words over \( \{a < b\} \) if and only if \( f \in \{L_a, R_b\}^* \).

**Theorem 6.5** A Sturmian word \( w \) over \( \{a, b\} \) is non-quasiperiodic if and only if \( w \) is an infinite Lyndon word over \( \{a < b\} \) or over \( \{b < a\} \).

**Proof.** Let \( w \) be a Sturmian word. By corollary 6.3, if \( w \) is an infinite Lyndon word then \( w \) is not quasiperiodic.

Assume now that \( w \) is not quasiperiodic. By Theorem 5.6, \( w = \lim_{n \to \infty} L_a^{d_1} R_b^{d_2} \ldots L_a^{d_{2n-1}} R_b^{d_{2n}}(a) \) or \( w = \lim_{n \to \infty} L_b^{d_1} R_a^{d_2} \ldots L_b^{d_{2n-1}} R_a^{d_{2n}}(a) \) for some integers \((d_k)_{k \geq 1}\) such that \( d_k \geq 1 \) for all \( k \geq 2 \) and \( d_1 \geq 0 \). Proposition 6.2 implies that, since \( a \) is a Lyndon word, for each \( n \geq 1 \), \( L_a^{d_1} R_b^{d_2} \ldots L_a^{d_{2n-1}} R_b^{d_{2n}}(a) \) is a Lyndon word over \( a < b \) and \( L_b^{d_1} R_a^{d_2} \ldots L_b^{d_{2n-1}} R_a^{d_{2n}}(a) \) is a Lyndon word over \( b < a \). Hence \( w \) is not quasiperiodic.

To end this section we study the converse of Corollary 6.3 and Fact 6.2.

The converse of Corollary 6.3 is not true in general. For instance we can consider any Sturmian word \( w \) over \( \{a, b\} \) and the word \( p = ababaab \). Then \( pw \) is not quasiperiodic since \( p \) is not balanced and so not a factor of \( w \). Moreover, since \( p \) starts with the letter \( a \), \( pw \) cannot be a Lyndon word if \( b < a \). It is neither a Lyndon word if \( b < a \) for any prefix \( p' \) of \( w \).

The converse of Fact 6.2 is also false: let \( w \) be an infinite word and \( p \) be an integer, if all prefixes of \( w \) of length greater than \( p + 1 \) are unbordered, then \( w \) is not necessarily quasiperiodic. To prove this, it is sufficient to consider the word \( w = aba^\infty \).

A more complex but interesting example, pointed out by P. Séébold (see Acknowledgements), is the well-known Thue-Morse word \( T \), fixed point of the morphism \( \mu \) such that \( \mu(a) = ab \) and \( \mu(b) = ba \). The word \( T \) starts with \( abb \) and any prefix of length at least 4 ends with \( a, ab \) or \( abb \). But \( T \) is not quasiperiodic: indeed it is well-known that \( T \) is overlap-free if it contains no factor of the form \( xuxuxx \) where \( x \) is a letter, or equivalently it contains no factor that can be written both \( pw \) and \( vs \) with \( |p| < |v| \) and we can observe that:

**Fact 6.6** An overlap-free infinite word is never quasiperiodic.
Proof. Let \( w \) be a \( u \)-quasiperiodic infinite word and let \((p_n u)_{n \geq 0}\) be a covering sequence of \( w \). If there exists \( n \geq 0 \) such that \( |p_{n+1}| - |p_n| < |u| \), then \( p_{n+1} u = p_n u s \) for a word \( s \) such that \( s = |p_{n+1}| - |p_n| < |u| \). Hence there exists a word \( p \) such that \( us = pu \), then \( w \) is not overlap-free. If for all \( n \geq 0 \) we have \( |p_{n+1}| - |p_n| = |u| \), then \( w \) is also not overlap-free.

Finally let us mention that this fact is not valid for finite words since there exist some overlap-free words that are square (see [19], cf. also [4] for a characterization of such words).

7 Sturmian morphisms and quasiperiodicity

We say that a morphism \( f \) is \emph{quasiperiod-free} if for any non-quasiperiodic word \( w \), \( f(w) \) is also non-quasiperiodic. A non-quasiperiod-free morphism will just be called \emph{quasiperiodic}. Let us observe that all Sturmian morphisms (except \( E \) and \( Id \)) are quasiperiodic. To verify it, it is sufficient to show that \( L_a, L_b, R_a \) and \( R_b \) are quasiperiodic. For \( L_a \) and \( R_a \) (case \( L_b \) and \( R_b \) are similar) we have: \( aba^\omega \) and \( ab^\omega \) are non-quasiperiodic although \( L_a(aba^\omega) = aba(ab)^\omega \) and \( R_a(ab^\omega) = a(ba)^\omega \) are \( aba \)-quasiperiodic.

In the previous section, we encounter (Lemma 5.2 and Fact 5.3) two different kinds of Sturmian morphisms. The morphism \( L_a L_b \) maps any word into a quasiperiodic one, whereas there exists a non-quasiperiodic word \( w \) such that \( L_a R_a(w) \) is not quasiperiodic. Generalizing these two examples we observe that the set of quasiperiodic morphisms can be partitioned using the following notions:

1. A morphism \( f \) on \( A \) is called \emph{strongly quasiperiodic} (resp. on a subset \( X \) of \( A^\omega \)) if for each non-quasiperiodic infinite word \( w \) (resp. \( w \in X \) ), \( f(w) \) is quasiperiodic.
2. A morphism \( f \) on \( A \) is called \emph{weakly quasiperiodic} (resp. on a subset \( X \) of \( A^\omega \)) if there exist two non-quasiperiodic infinite words \( w, w' \) (resp. \( w, w' \in X \) ) such that \( f(w) \) is quasiperiodic, and \( f(w') \) is non-quasiperiodic.

The aim of this section is to answer the two following questions:

- Which are the strongly (resp. weakly) quasiperiodic Sturmian morphisms?
- Which are the strongly (resp. weakly) quasiperiodic Sturmian morphisms on (the set of) Sturmian words?

We note that the two questions have different answers. Indeed \( L_a R_a \) as shown by Lemma 5.2 is strongly quasiperiodic on Sturmian words, but as already said, \( L_a R_a(ba^\omega) \) is not quasiperiodic. Of course, any strongly quasiperiodic Sturmian morphism is strongly quasiperiodic on Sturmian words, or equivalently (since a Sturmian morphism is quasiperiodic), any weakly quasiperiodic Sturmian morphism on Sturmian words is weakly quasiperiodic.

7.1 A property of strongly quasiperiodic morphisms

Before going further, we mention the following immediate result:

**Lemma 7.1** Let \( f \) be a morphism. If there exist morphisms \( f_1, f_2, f_3 \) such that \( f = f_1 f_2 f_3 \) and such that \( f_2 \) is strongly quasiperiodic, then \( f \) is strongly quasiperiodic.
We observe that (quite naturally) Lemma 7.1 becomes false when replacing strongly quasiperiodic by weakly quasiperiodic. For instance, taking \( f_1 = I_d, f_2 = L_a \) and \( f_3 = L_b \), we have \( f_2 \) weakly quasiperiodic and \( f_1f_2f_3 \) strongly quasiperiodic. There are cases where we can have \( f_2 \) weakly quasiperiodic and \( f_1f_2f_3 \) quasiperiod-free, but this is not possible when \( f_1, f_2 \) and \( f_3 \) are Sturmian morphisms since all Sturmian morphisms are quasiperiodic. To give an example of such a case, we need the following result:

**Lemma 7.2** The morphism \( g \) defined by \( g(a) = abab \) and \( g(b) = aaaa \) is a quasiperiod-free morphism.

**Proof.** Let \( w \) be an infinite word such that \( g(w) \) is quasiperiodic. We show that \( w \) is also quasiperiodic. Let \( u \) be the smallest quasiperiod of \( g(w) \). Since \( u \) is a prefix of \( g(w) \), \( u = g(v)p \) for a proper prefix \( p \) of \( g(a) = abab \) or of \( g(b) = aaaa \): \( p \in \{ \varepsilon, a, aa, aaa, ab, aba \} \). First we observe that if \( a \) or \( b \) does not occur in \( w \), then \( w \) is quasiperiodic. From now on we assume that both \( a \) and \( b \) occur in \( w \). Consequently \( |v|_a \neq 0 \) and \( |v|_b \neq 0 \). It follows that \( g(v) \) starts with \( (ab)^naaaa \) for an integer \( n \geq 0 \) and with \( a^mabab \) for an integer \( m \geq 0 \): of course \( m = 0 \) or \( n = 0 \). Moreover \( g(v) \) ends with \( aaaa(ab)^{n'} \) for an integer \( n' \geq 0 \) and with \( ababa^{m'} \) for an integer \( m' \geq 0 \): once again \( m' = 0 \) or \( n' = 0 \). By Lemma 4.1 \( uu \) is a factor of \( g(w) \). We then deduce that \( p = \varepsilon \) since for all the other potential values, none of the words in \( \{ aaaa(ab)^{n'}, ababa^{m'} \} p \{ (ab)^2 aaaa, a^m abab \} \) could be a factor of \( g(w) \). Let \( (pu)_l \geq 0 \) be a covering sequence of prefixes of \( g(w) \). As done in the proof of Lemma 7.4, we can find a covering sequence \( (p'_v)_l \geq 0 \) of prefixes of \( w \): the word \( v \) is a quasiperiod of \( w \). \( \Box \)

Now let us consider the morphisms \( f_1 = I_d, f_2 = L_a \), and \( f_3 \) defined by \( f_3(a) = bb \), \( f_3(b) = aaaa \). By the previous lemma \( f_1f_2f_3 = g \) is quasiperiod-free whereas \( f_2 \) is weakly quasiperiodic.

To end this section, we let the reader verify that \( f_3 \) is quasiperiod-free and more generally that any morphism \( h \) defined by \( h(a) = a^i, h(b) = b^j \) with \( i \geq 1 \) and \( j \geq 1 \) is quasiperiod-free.

### 7.2 Weakly and strongly quasiperiodic Sturmian morphisms

In this section, we characterize weakly quasiperiodic Sturmian morphisms. (Equivalently this characterizes strongly quasiperiodic Sturmian morphisms since any Sturmian morphism is weakly or strongly quasiperiodic.)

**Proposition 7.3** A Sturmian morphism is weakly quasiperiodic if and only if it belongs to the set

\[
\{ E, Id \} \{ L_a, R_b \}^* \{ L_a, R_a \}^* \cup \{ E, Id \} \{ L_b, R_a \}^* \{ L_b, R_b \}^*.
\]

The proof, given at the end of the section, is a consequence of the next lemmas.

**Lemma 7.4** Let \( f \) be a morphism in \( \{ L_a, L_b, R_a, R_b \}^* \) different from the identity. The morphism \( f \) belongs to \( \{ L_a, R_b \}^* \{ L_a, R_a \}^* \cup \{ L_b, R_a \}^* \{ L_b, R_b \}^* \) if and only if \( f \) cannot be written \( f = f_1f_2f_3 \) with \( f_1, f_3 \in \{ L_a, L_b, R_a, R_b \}^* \) and \( f_2 \) verifying one of the four following properties:

1. \( f_2 \in L_a \{ L_a, L_b, R_a, R_b \}^* L_b \cup L_b \{ L_a, L_b, R_a, R_b \}^* L_a \), or
2. \( f_2 = R_agsL_a \) with \( g \not\in \{ R_a, L_a \}^* \) or \( f_2 = R_6gsL_b \) with \( g \not\in \{ R_b, L_b \}^* \), or
3. \( f_2 \in R_a R_b^* R_a \) or \( f_2 \in R_b R_a^* R_b \), or
4. \( f_2 \in R_a^*L_a^+R_b = L_a^+R_a^+R_b \) or \( f_2 \in R_b^+L_b^+R_a = L_b^+R_b^+R_a \).

Proof. First we let the reader verify using Theorem 3.2 that if \( f \) belongs to \( \{L_a, R_b\}^\ast\{L_a, R_a\}^\ast \cup \{L_b, R_a\}^\ast\{L_b, R_b\}^\ast \) then it cannot be written \( f = f_1f_2f_3 \) with \( f_1, f_2, f_3 \) as in the lemma.

From now on assume that \( f \) cannot be written \( f = f_1f_2f_3 \) with \( f_1, f_2, f_3 \) as in the lemma. Let \( g_1, \ldots, g_n \) \((n \geq 1 \text{ since } f \text{ is not the identity}) \in \{L_a, L_b, R_a, R_b\} \) such that \( f = g_1 \ldots g_n \).

We first consider the case where \( g_1 = L_a \). By Impossibility 1 for \( f_1 \), for each \( i > 1 \), \( g_i \neq L_b \). If \( g_i \) exists an integer \( i > 1 \) such that \( g_i = R_a \), then \( g_1 \ldots g_i = hL_aR_a^i \) or \( g_1 \ldots g_i = hR_bR_a^i \) for a morphism \( h \) and an integer \( l \geq 1 \). In the first case by Impossibility 4 for \( f_2 \), for all integer \( j > i \), \( f_j \neq R_b \). In the second case by Impossibilities 3 and 4 for \( f_2 \), for all integer \( j > i \), we also have \( f_j \neq R_b \). Thus \( f \in L_a\{R_b, L_a\}^\ast\{L_a, R_a\}^\ast \).

Assume now the more general case (than \( g_1 = L_a \)) where there exists an integer \( i \geq 1 \) such that \( g_i = L_a \) and \( g_j \neq L_a \) for \( 1 \leq j < i \) (the first occurrence of \( L_a \) appears at the position \( i \)). Namely as above, we show that \( g = g_1 \ldots g_n \in L_a\{R_a, L_a\}^\ast\{L_a, R_a\}^\ast \). By Impossibility 1 for \( f_2 \), for each integer \( j \), \( 1 \leq j < i \), \( g_j \neq L_a \). Thus \( g_j \in \{R_a, R_b\} \) for each \( 1 \leq j < i \). We have three cases: If \( f \in R_b^\ast g \), then by Impossibility 4 for \( f_2 \), we have \( f \in L_a\{R_a, L_a\}^\ast\{L_a, R_a\}^\ast \). If \( f \in hR_b^iR_b^\ast g \) for a morphism \( h \in \{R_a, R_b\}^\ast \), then by Impossibility 2 for \( f_2 \), \( h \in R_b^i \) and so \( f \in R_b^iR_b^\ast g \); then by Impossibilities 3 and 4 for \( f_2 \) we have \( f \in \{L_a, R_a\}^\ast\{L_a, R_a\}^\ast \). If \( f \in R_b^i g \), \( f \in \{L_a, R_b\}^\ast\{L_a, R_a\}^\ast \). So when there exists an integer \( i \geq 1 \) such that \( g_i = L_a \), \( f \in \{L_a, R_b\}^\ast\{L_a, R_a\}^\ast \).

The case where there exists an integer \( i \geq 1 \) such that \( g_i = L_b \) leads similarly to \( f \in \{L_b, R_a\}^\ast\{L_b, R_b\}^\ast \).

Now we have to consider the case where for all \( i \), \( 1 \leq i \leq n \), \( g_i \notin \{L_a, L_b\} \). Then by Impossibility 3 for \( f_2 \), necessarily, \( f \in R_a^\ast R_b^\ast \cup R_b^\ast R_a^\ast \).

Lemma 7.5 Every morphism \( f \) in \( L_a\{L_a, L_b, R_a, R_b\}^\ast L_b \cup L_b\{L_a, L_b, R_a, R_b\}^\ast L_a \) is strongly quasiperiodic.

Proof. We only prove the result for \( f \) in \( L_a\{L_a, L_b, R_a, R_b\}^\ast L_b \) (the other case is similar exchanging the roles of the letters \( a \) and \( b \)). Let \( f = L_a f_1 f_2 \ldots f_n L_b \) with \( n \geq 0 \) and \( f_i \in \{L_a, L_b, R_a, R_b\} \) for all \( 1 \leq i \leq n \). We prove by induction on \( n \) that there exist morphisms \( g \) and \( h \) such that \( f = g L_a L_b h \) (and so from Lemma 7.1 and Fact 5.3, \( f \) is strongly quasiperiodic). The property is immediate for \( n = 0 \). Assume now \( n \geq 1 \). If there exists \( i \) between 1 and \( n \) such that \( f_i = L_a \) or \( f_i = L_b \), we can apply the induction hypothesis and Lemma 7.1 to conclude. Now suppose that for all \( i \), \( f_i \notin \{L_a, L_b\} \). Three cases are possible:

- \( f_1 = R_a \), since \( L_a R_a = R_a L_a \) from Theorem 3.2, \( f = R_a L_a f_1 \ldots f_n L_b \) and we conclude by the induction hypothesis.

- If \( f_n = R_b \) we can proceed similarly.

- Assume now \( f_1 = R_b \) and \( f_n = R_a \) (this implies \( n \geq 2 \)). Let \( j \) be the greatest integer \((1 \leq j \leq n) \) such that \( f_j = R_b \). Then \( f = L_a f_1 \ldots f_{j-1} R_b R_b^{n-j} L_b \) and by Theorem 3.2 \( f = L_a f_1 \ldots f_{j-1} L_b L_a^{n-j} R_b \). We conclude by the induction hypothesis.

Remark: we could have used another approach observing that \( L_a R_b(w) \) \((L_a R_b(a) = aab, L_a R_b(b) = ab) \) is a\( b \)-quasiperiodic for every infinite word \( w \) starting with \( b \), and deducing that every morphism of the form \( L_a R_b f L_b \) with \( f \in \{L_a, R_a, R_b\}^\ast \) is strongly quasiperiodic.
Lemma 7.6 Every morphism \( f = R_agL_a \) with \( g \notin \{ R_a, L_a \}^* \) or \( f = R_bgL_b \) with \( g \notin \{ R_b, L_b \}^* \) is strongly quasiperiodic.

Proof. We only prove the first case, the other one is similar. Let \( g = g_1 \ldots g_n \) (necessarily \( n \geq 1 \)) such that \( g \notin \{ R_a, L_a \}^* \) and for each \( i \) between 1 and \( n \), \( g_i \in \{ L_a, L_b, R_a, R_b \} \). If there exists an integer \( i \) such that \( g_i = L_b \) then the result is immediate from Lemma 7.3. Consequently we consider that \( g \in (\{ L_a, R_a \}^* R_b)^+ \{ L_a, R_a \}^* \). Thus the morphism \( f \) can be decomposed \( f = f_1 h f_2 \) with \( h \in R_a L_a^* R_b^* R_a^* L_a \). If \( i, j \geq 0, k \geq 1 \) are the integers such that \( h = L_a^i R_a^j R_b^k L_a \), Theorem 7.7 shows that \( h = L_a^i L_a L_a^k R_a R_a^i \). Consequently Lemmas 7.4 and 7.5 imply that \( h \) is strongly quasiperiodic. □

Remark: here again we could have used another approach observing that \( R_a R_b(w)(R_a R_b(a) = aba, R_a R_b(b) = ba) \) is aba-quasiperiodic for every infinite word \( w \) starting with \( a \), and deducing that every morphism of the form \( R_a R_b f L_a \) with \( f \in \{ L_a, R_a, R_b \}^* \) is strongly quasiperiodic.

This approach is used to prove:

Lemma 7.7 Any morphism \( f \) in \( R_a R_b^+ R_a \cup R_b R_a^+ R_b \) is strongly quasiperiodic.

Proof. Let \( j \geq 1 \) be an integer such that \( f = R_a R_a^j R_a \). Let \( w \) be a word. If \( w \) starts with \( b \), \( R_b R_a(w) \) is \( bab \)-quasiperiodic, and so \( f(w) \) is quasiperiodic. If \( w \) starts with \( a \), \( R_b^{j-1} R_a(w) \) also starts with \( a \). Then \( R_a R_b^j R_a(a) \) is \( aba \)-quasiperiodic. □

Lemma 7.8 Every morphism \( f \) in \( R_a^+ L_a^+ R_b = L_a^+ R_a^+ R_b \) or in \( R_b^+ L_b^+ R_a = L_b^+ R_b^+ R_a \) is strongly quasiperiodic.

Proof. Theorem 7.2 implies \( R_a^+ L_a^+ R_b = L_a^+ R_a^+ R_b \) and \( R_b^+ L_b^+ R_a = L_b^+ R_b^+ R_a \).

We prove only the first case, the other one is similar. Let \( n \geq 1 \). It is easy to see that \( R_a L_a^n R_b(w)(R_a R_a^j R_a(a) = aa^nb, R_a L_a^n R_b(b) = a^nb) \) is \( a^{n+1}ba \)-quasiperiodic if \( w \) starts with \( a \), and is \( a^nbaa \)-quasiperiodic if \( w \) starts with \( b \). By Lemma 7.4, any morphism in \( R_a^+ L_a^+ R_b \) is quasiperiodic. □

Proof of Proposition 7.3.

From Theorem 7.1, \( EL_a = L_b E \) and \( ER_a = R_b E \), so any Sturmian morphism can be written \( fg \) with \( f \in \{ Id, E \} \) and \( g \in \{ L_a, L_b, R_a, R_b \}^* \). Thus Proposition 7.3 is a consequence of the following one: a morphism \( f \) in \( \{ L_a, L_b, R_a, R_b \}^* \) is weakly quasiperiodic if and only if \( f \) belongs to the set \( X = \{ L_a, R_a \}^* \{ L_a, R_b \}^* \cup \{ L_b, R_a \}^* \{ L_b, R_b \}^* \).

To prove this, assume first that \( f \in \{ L_a, L_b, R_a, R_b \}^* \) is weakly quasiperiodic. By Lemma 7.1, this morphism cannot be written \( f = f_1 f_2 f_3 \) with \( f_2 \) a strongly quasiperiodic morphism. Hence by Lemmas 7.4, 7.5, 7.6, 7.7 and 7.8, \( f \) belongs to \( X \).

Assume now that \( f \in X \). Since \( f \) is Sturmian, it is quasiperiodic and so we just have to prove the existence of one word such that \( f(w) \) is not quasiperiodic. So we just have to prove the existence of one word \( w \) such that \( f(w) \) is not quasiperiodic. We do it for \( f \in \{ L_a, R_a \}^* \{ L_a, R_a \}^* \) (the other case is similar). There exist morphisms \( g \in \{ L_a, R_a \}^* \) and \( h \in \{ L_a, R_a \}^* \) such that \( f = gh \). We can verify that \( h(aba^n) = a^nba^n \) for an integer \( n \geq 1 \), and so is a balanced word. By Lemmas 7.3 and 7.5, we thus deduce that \( (g(h(aba^n))) = f(aba^n) \) is not quasiperiodic. □
7.3 Weakly Sturmian morphisms on Sturmian words

Proposition 7.3 and Lemma 5.2 show that some morphisms, as for instance $L_aR_a$, are weakly quasiperiodic whereas they are strongly quasiperiodic on Sturmian words. This section allows us to characterize all these morphisms. Let us recall that since a Sturmian morphism is quasiperiodic, any Sturmian morphism is weakly or strongly quasiperiodic on Sturmian words.

**Proposition 7.9** A Sturmian morphism different from $E$ and $Id$ is weakly quasiperiodic on Sturmian words if and only if it belongs to $\{E, Id\}\{L_a, R_b\}^* \cup \{E, Id\}\{L_b, R_a\}^*$.

**Proof.**

Let us make a preliminary remark: for any morphism $f$, $f$ is weakly quasiperiodic on Sturmian words if and only if $Ef$ is weakly quasiperiodic on Sturmian words (since for any word $w$, $w$ is quasiperiodic if and only if $E(w)$ is quasiperiodic).

Assume first $f \in \{E, Id\}\{L_a, R_b\}^* \cup \{E, Id\}\{L_b, R_a\}^*$. Without loss of generality, we can assume $f \in \{L_a, R_b\}^* \cup \{L_b, R_a\}^*$. If $f$ belongs to $\{L_a, R_b\}^*$ (resp. to $\{L_b, R_a\}^*$), using Theorem 7.3 we observe that $f((L_aR_b)^\omega)$ (resp. $f((L_bR_a)^\omega)$) is not quasiperiodic. Since any Sturmian morphism is quasiperiodic, $f$ is weakly quasiperiodic on Sturmian words.

Now assume $f$ is weakly quasiperiodic on Sturmian words. Observe that from Theorem 5.2, $f \in \{E, Id\}\{L_a, L_b, R_a, R_b\}^*$. Without loss of generality, from the preliminary remark, we can assume that $f$ belongs to $\{L_a, L_b, R_a, R_b\}^*$ and prove that $f \in \{L_a, R_b\}^* \cup \{L_b, R_a\}^*$. By Proposition 7.3, $f$ belongs to $\{L_a, R_b\}^* \{L_a, R_a\}^* \cup \{L_b, R_a\}^* \{L_b, R_b\}^*$. Assume by contradiction that $f \notin \{L_a, R_b\}^* \cup \{L_b, R_a\}^*$. One of the following four cases holds:

1. $f = gL_aR_a$ with $g \in \{L_a, R_b\}^* \{L_a, R_a\}^*$;
2. $f = gR_bR_a^i$ with $g \in \{L_a, R_b\}^*, i \geq 1$;
3. $f = gL_bR_b$ with $g \in \{L_b, R_a\}^* \{L_b, R_b\}^*$;
4. $f = gR_aR_b^i$ with $g \in \{L_b, R_a\}^*, i \geq 1$.

**Case 1:** Assume $f = gL_aR_a$ and let $w$ be a non-quasiperiodic Sturmian word. By Lemma 5.2, $f(w)$ is quasiperiodic.

**Case 2:** Assume $f = gR_bR_a^i$ and let $w$ be a non-quasiperiodic Sturmian word. By Theorem 5.6, $w$ can be decomposed over $\{L_a, R_b\}$ or over $\{L_b, R_a\}$. So $f(w) = gR_bR_a^i L_a(w')$ or $f(w) = gR_bR_a^{i+j} L_b(w')$ for a (non-quasiperiodic) Sturmian word $w'$ and an integer $j \geq 0$. Thus by Lemma 5.2, Lemma 7.3 and Lemma 7.4, $f(w)$ is quasiperiodic.

**Cases 3 and 4** are respectively similar to cases 1 and 2. In all cases, $f(w)$ is quasiperiodic for any non-quasiperiodic Sturmian word $w$, and so for any Sturmian word (by Fact 1.2). Thus $f$ is strongly quasiperiodic on Sturmian words. This is a contradiction, so $f \notin \{L_a, R_b\}^* \cup \{L_b, R_a\}^*$.

\[ \square \]

**Acknowledgements**

Facts 5.2 and 5.3 were respectively observed by J.P. Duval and P. Séébold during a talk given by the second author at the "Premières Journées Marseille-Rouen en combinatoire des mots" taking place in Rouen in June 2005. Many thanks to them and to J. Cassaigne, C. Mauduit and J.Néraud, the organizers of these "Journées".
