L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Indirect controllability of locally coupled systems under geometric conditions

Fatiha Alabau-Boussouira, Matthieu Léautaud

December 8, 2010

Abstract

We consider systems of two wave/heat/Schrödinger-type equations coupled by a zero order term, only one of them being controlled. We prove an internal and a boundary null-controllability result in any space dimension, provided that both the coupling and the control regions satisfy the Geometric Control Condition. This includes several examples in which these two regions have an empty intersection.

Abstract

Contrôlabilité indirecte de systèmes localement couplés sous des conditions géométriques. On s’intéresse à des systèmes constitués de deux équations d’ondes, de la chaleur ou de Schrödinger, couplées par un terme d’ordre zéro, et dont seulement l’une est contrôlée. En supposant que les zones de couplage et de contrôle satisfont toutes deux la Condition Géométrique de Contrôle, on montre un résultat de contrôlabilité interne et frontière en dimension quelconque d’espace. Ceci fournit de nombreux exemples pour lesquels ces deux régions ne s’intersectent pas.

Version française abrégée

Durant les dix dernières années, les propriétés de contrôlabilité des systèmes paraboliques du type

\[
\begin{align*}
\begin{cases}
\theta u_1' - \Delta u_1 + au_1 + \delta pu_2 = bf & \text{dans } (0, T) \times \Omega, \\
\theta u_2' - \Delta u_2 + au_2 + pu_1 = 0 & \text{dans } (0, T) \times \Omega, \\
u_1 = u_2 = 0 & \text{sur } (0, T) \times \partial \Omega,
\end{cases}
\end{align*}
\]

(1)

avec \( \theta = 0 \), ont été étudiées intensivement. Ici, \( a, b, c, p \) sont des fonctions réelles régulières de \( x \in \Omega \), avec \( b \geq 0 \) et \( p \geq 0 \), \( \delta > 0 \) est un paramètre, \( -\Delta \), est un opérateur autoadjoint uniformément elliptique sur \( \Omega \), et \( f \) est le contrôle. Le résultat général concernant ces systèmes, prouvé par différentes méthodes dans [16, 4, 7, 9] est un théorème de contrôlabilité à zéro dès qu’on suppose \( \{p > 0\} \cap \{b > 0\} = 0 \). Qu’en est-il du cas \( \{p > 0\} \cap \{b > 0\} = \emptyset \)? Le second problème auquel on s’intéresse ici est le problème du contrôle frontière associé à (1) (cf.(4)). S’il semble résolu en dimension 1 d’espace pour \( a \) et \( p \) constants (voir [6]), il reste complètement ouvert en dimension supérieure ou pour des coefficients variables. Pour ces deux problèmes, il semblerait que la théorie des équations paraboliques et les outils utilisés se heurtent pour le moment à des sérieuses difficultés. D’autre part, on sait depuis [15] que les propriétés de contrôlabilité des équations hyperboliques se transmettent aux équations paraboliques. Poursuivant l’étude initiée dans [2], nous répondons aux deux questions ci-dessus pour le système hyperbolique (3) (consistant à remplacer \( \theta u' \) par \( u''_j \), pour \( j = 1, 2 \), dans (1)) sous certaines hypothèses. Nous en déduisons ensuite une réponse partielle à ces questions pour (1).

Dans le cadre du contrôle frontière, on renvoie aux systèmes (4) et (5) ci-dessous, pour lesquelles le contrôle agit par la condition au bord \( u_1|_{\Omega_b} = b_0f \), avec \( b_0 \in C^\infty(\partial \Omega) \), \( b_0 \geq 0 \). On appellera GCC (resp. GCC\(_{b} \)) la condition de contrôle géométrique interne (resp. frontière) de [5], que nous rappelons dans la section 2.

Pour formuler nos résultats, on utilisera les hypothèses suivantes:

(i) L’Opérateur \( -\Delta + a \) est uniformément coercif sur \( \Omega \).

(ii) On a \( \{p > 0\} \supset \overline{\omega}_p \) pour un ouvert \( \omega_p \subset \Omega \) et on pose \( p^* := \|p\|_{L^\infty(\Omega)} \).

(iii) On a \( \{b > 0\} \supset \overline{\omega}_b \) (resp. \( \{b_0 > 0\} \supset \Gamma_b \)) pour un ouvert \( \omega_b \subset \Omega \) (resp. \( \Gamma_b \subset \partial \Omega \)).

---

‡ Laboratoire POEMS, INRIA Paris-Rocquencourt/ENSTA, CNRS UMR 2706, France.
Theorem 0.1 (Systèmes d’équations d’ondes). On suppose que (i) est satisfaite, que \( \omega_p \) satisfait GCC, et que \( \omega_b \) (resp. \( \Gamma_b \)) satisfait GCC (resp. GCC\(_{\partial} \)). Il existe alors une constante \( \delta > 0 \) telle que pour tout \( (\delta, p^*) \) satisfaisant \( \sqrt{\delta}p^* < \delta \), il existe un temps \( T_0 > 0 \) tel que pour tout \( T > T_0 \), tous \( p, b \) (resp. \( b_{\partial} \)) satisfaisant (ii) et (iii), et toutes données initiales \( (u_0^p, u_1^p, u_2^p) \in H^1_0(\Omega) \times H^1_0(\Omega) \times L^2_0(\Omega) \) (resp. \( (u_0^b, u_1^b, u_2^b) \in L^2(\Omega) \times H^1(\Omega) \times L^2(\Omega) \)), il existe un contrôle \( f \in L^2(0, T \times \Omega) \) (resp. \( f \in L^2(0, T \times \partial \Omega) \)) tel que la solution de (3) (resp. (5)) vérifie \( (u_1, u_2)|_{t=T} = 0 \).

On remarque que les espaces dans lesquels \( u_1 \) et \( u_2 \) sont contrôlés ne sont pas les mêmes, ce qui est naturel. Ce résultat est monté dans un cadre abstrait (voir Section 3), incluant aussi des systèmes de plaques couplées. On en déduit, grâce aux méthodes de transmutation de [15, 11, 13, 12] les résultats suivants pour deux équations de diffusion ou de Schrödinger couplées.

Theorem 0.2 (Systèmes d’équations de diffusion). On suppose que (i) est satisfaite, que \( \omega_p \) satisfait GCC, et que \( \omega_b \) (resp. \( \Gamma_b \)) satisfait GCC (resp. GCC\(_{\partial} \)). Il existe alors une constante \( \delta > 0 \) telle que pour tout \( (\delta, p^*) \) satisfaisant \( \sqrt{\delta}p^* < \delta \), pour tout \( T > 0, \theta \in (-\pi/2, \pi/2) \), pour tous \( p, b \) (resp. \( b_{\partial} \)) satisfaisant (ii) et (iii), et toutes données initiales \( (u_0^p, u_2^p) \in (L^2(\Omega))^2 \) (resp. \( (u_0^b, u_2^b) \in (H^{-1}(\Omega))^2 \)), il existe un contrôle \( f \in L^2((0, T) \times \Omega) \) (resp. \( f \in L^2((0, T) \times \partial \Omega) \)) tel que la solution de (1) (resp. (4)) vérifie \( (u_1, u_2)|_{t=T} = 0 \).

Ce résultat répond donc partiellement aux deux questions posées, fournissant de nombreux exemples pour lesquels \( \{p > 0\} \cap \{b > 0\} = \emptyset \) ainsi qu’un résultat de contrôle frontière en toute dimension d’espace pour un couplage variable. Cependant, on notera que les hypothèses géométriques ne sont pas naturelles pour des équations paraboliques. Par conséquent, le théorème 0.2 n’est qu’un premier pas pour cette étude.

Theorem 0.3 (Systèmes d’équations de Schrödinger). Sous les hypothèse du théorème 0.2, le même résultat de contrôlabilite est valide pour le système (1) (resp. (4)) avec \( \theta = \pm \pi/2 \), pour des données initiales \( (u_1^p, u_2^p) \in L^2(\Omega) \times H_0^1(\Omega) \) (resp. \( (u_1^b, u_2^b) \in H^{-1}(\Omega) \times L^2(\Omega) \)).

1 Introduction

During the last decade, the controllability properties of coupled parabolic equations like

\[
\begin{align*}
  e^{\theta}u_1' - \Delta u_1 + au_1 + \delta pu_2 &= bf \quad \text{in } (0, T) \times \Omega, \\
  e^{\theta}u_2' - \Delta u_2 + au_2 + pu_1 &= 0 \quad \text{in } (0, T) \times \Omega, \\
  u_1 &= u_2 = 0 \quad \text{on } (0, T) \times \partial \Omega, \\
  (u_1, u_2)|_{t=0} &= (u_0^p, u_0^b) \quad \text{in } \Omega,
\end{align*}
\]

with \( \theta = 0 \), have been intensively studied. Here, \( \Delta \) is a selfadjoint elliptic operator, and all the parameters are precisely defined in Section 2. The null-controllability problem under view is the following: given a time \( T > 0 \) and initial data, is it possible to find a control function \( f \) so that the state has been driven to zero in time \( T \)? It has been proved in [16, 4, 7, 9] with different methods that System (2) is null-controllable as soon as \( \{p > 0\} \cap \{b > 0\} \neq \emptyset \). In these works, the case \( \{p > 0\} \cap \{b > 0\} = \emptyset \) has been left as an open problem. However, Kavian and de Teresa [8] have proved for a cascade system (i.e. taking \( \delta = 0 \) in (2)) that approximate controllability holds. The natural question is then whether or not null-controllability (which is a stronger property) still holds in the case \( \{p > 0\} \cap \{b > 0\} = \emptyset \)?

The second Problem under interest here is the boundary controllability of systems like (2) (or more precisely System (4) below). The recent work [6] studies slightly more general systems in one space dimension and with constant coupling coefficients. The cases of higher space dimensions and varying coupling coefficients (and in particular when the coefficients vanish in a neighborhood of the boundary) are to our knowledge completely open.

Concerning these two open problems, it seems that the parabolic theory and associated tools encounter for the moment some essential difficulties.

On the other hand, it is known from [15] that controllability properties can be transferred from hyperbolic equations to parabolic ones. And it seems, at least for boundary control problems, that the theory for coupled hyperbolic equations of the type

\[
\begin{align*}
  u_1'' - \Delta u_1 + au_1 + \delta pu_2 &= bf \quad \text{in } (0, T) \times \Omega, \\
  u_2'' - \Delta u_2 + au_2 + pu_1 &= 0 \quad \text{in } (0, T) \times \Omega, \\
  u_1 &= u_2 = 0 \quad \text{on } (0, T) \times \partial \Omega, \\
  (u_1, u_2, u_1', u_2')|_{t=0} &= (u_0^p, u_0^b, u_0^p, u_0^b) \quad \text{in } \Omega,
\end{align*}
\]

is better understood (see [2]), even less studied. In the case of varying coefficients and several space-dimensions, the associated stabilization problem is addressed in [1, 3].
In the present work, we answer these two questions for hyperbolic problems improving the results of [2, 3], and then deduce a (partial) solution to the two open questions raised above. Indeed, we prove that Systems (2)-(3) are null-controllable (in appropriate spaces) as soon as \( p > 0 \) and \( b > 0 \) both satisfy the Geometric Control Condition (recalled below) and \( \sqrt{p}||p||_{L^1(\Omega)} \) satisfies a smallness assumption. This contains several examples with \( \{p > 0\} \cap \{b > 0\} = \emptyset \) in any space-dimension, and partially answers to the first question. We prove as well that the same controllability result holds for boundary control, which partially answers to the second question. Of course, the geometric conditions needed here are essential (and even sharp) for coupled waves, but inappropriate for parabolic equation. However, this is a first step towards a better understanding of these types of systems. In one space dimension in particular, the geometric conditions are reduced to a non-emptiness condition and are hence optimal for parabolic systems as well. Similar results have been obtained simultaneously in [14] with different methods in one space dimension for cascade systems.

In this note, we first state our results for wave/heat/Shrödinger-type Systems. Then, we introduced an abstract setting adapted to these problems and give some elements of the proof in this context.

Acknowledgements. The authors want to thank B. Dehman for discussions on the article [5], S. Ervedoza for having pointed out the papers [11, 12], and L. Miller for discussions on these two articles. The first author would like to thank the Fondation des Sciences Mathématiques de Paris and the organizers of the IHP trimester on control of PDE’s for their support. The second author wishes to thank O. Glass and J. Le Rousseau for very fruitful discussions and encouragements.

Both authors were partially supported by l’Agence Nationale de la Recherche under grant ANR-07-JCJC-0139-01 and the GDRE CONEDP (CNRS/INDAM/UP).

2 Main results

Let \( \Omega \) be a bounded domain in \( \mathbb{R}^n \) with smooth (say \( \mathcal{C}^{\infty} \)) boundary (or a smooth connected compact riemannian manifold with or without boundary) and \( \Delta_c = \text{div}(c \nabla) \) a (negative) Laplace operator (or Laplace Beltrami operator with respect to the riemannian metric) on \( \Omega \). Here, \( c \) denotes a smooth (say \( \mathcal{C}^{\infty} \)) positive symmetric matrix i.e. in particular \( C^{-1}_0|\xi|^2 \leq c(x)\xi \cdot \xi \leq C_0|\xi|^2 \) for some \( C_0 > 1 \), for all \( x \in \bar{\Omega}, \xi \in \mathbb{R}^n \). We consider the control problems (2) with \( \theta \in [-\pi/2, \pi/2] \), including Schrödinger-type systems for \( \theta = \pm \pi/2 \) and diffusion-type systems for \( \theta = (-\pi/2, \pi/2) \), and (3) consisting in a wave-type system, with only one control force. In these systems, \( a = a(x) \), \( p = p(x) \) and \( b = b(x) \) are smooth real-valued functions on \( \Omega, \delta > 0 \) is a constant parameter and \( f \) is the control function, that can act on the system.

We shall also consider the same systems controlled from the boundary through the (smooth) real-valued function \( b_0 \):

\[
\begin{align*}
\left\{ \begin{array}{ll}
\epsilon^0 u_1' - \Delta_c u_1 + au_1 + \delta pu_2 = 0 & \text{in } (0, T) \times \Omega, \\
\epsilon^0 u_2' - \Delta_c u_2 + au_2 + pu_1 = 0 & \text{in } (0, T) \times \Omega, \\
u_1 = b_0 f, \quad u_2 = 0 & \text{on } (0, T) \times \partial \Omega,
\end{array} \right.
\end{align*}
\]

(4)

\[
\begin{align*}
\left\{ \begin{array}{ll}
u_1'' - \Delta_c u_1 + au_1 + \delta pu_2 = 0 & \text{in } (0, T) \times \Omega, \\
u_2'' - \Delta_c u_2 + au_2 + pu_1 = 0 & \text{in } (0, T) \times \Omega, \\
u_1 = b_0 f, \quad u_2 = 0 & \text{on } (0, T) \times \partial \Omega,
\end{array} \right.
\end{align*}
\]

(5)

We first notice that, on the space \((L^2(\Omega))^2\) endowed with the inner product \((u, v)_\delta = (u_1, v_1)_{L^2(\Omega)} + \delta(u_2, v_2)_{L^2(\Omega)}\), the operator \(A_\delta = \left( \begin{array}{cc} -\Delta_c + a & \delta p \\
\delta p & -\Delta_c + a \end{array} \right)\), with domain \(D(A_\delta) = (H^2(\Omega) \cap H^1_0(\Omega))^2\), is selfadjoint. As a consequence, for \( f \in L^2((0, T) \times \Omega), \) the Cauchy problem (2), resp. (3), is well-posed in \((L^2(\Omega))^2\), resp. \((H^2(\Omega))^2 \times (L^2(\Omega))^2\), in the sense of semigroup theory. Then, taking \( f \in L^2((0, T) \times \partial \Omega)\) the initial-boundary value problem (4), resp. (5), is well-posed in \((H^{-1}(\Omega))^2\), resp. \((L^2(\Omega))^2 \times (H^{-1}(\Omega))^2\), in the sense of transposition solution (see [10]).

An important remark to make before addressing the controllability problem is concerned with the regularity of solutions of (3)-(5). If one takes for system (3) (resp. (5)) an initial data \((u^0_1, u^0_2, u^1_1, u^1_2) \in H^2(\Omega) \times H^2 \cap H^1_0(\Omega) \times L^2(\Omega) \times H^2_0(\Omega)\) (resp. \((u^0_1, u^0_2, u^1_1, u^1_2) \in L^2(\Omega) \times H^2(\Omega) \times H^{-1}(\Omega) \times L^2(\Omega)\)), and a control \( f \in L^2((0, T) \times \Omega)\) (resp. \( f \in L^2((0, T) \times \partial \Omega)\), then the state \((u_1, u_2, u'_1, u'_2)\) remains in the space \(H^2_0(\Omega) \times H^2 \cap H^1_0(\Omega) \times L^2(\Omega) \times H^2_0(\Omega)\) (resp. \(L^2(\Omega) \times H^2_0(\Omega) \times H^{-1}(\Omega) \times L^2(\Omega)\)) for all time. Recall that for Systems (3) and (5), the null-controllability is equivalent to the exact controllability. As a consequence, it is not possible to take for instance zero as initial data to reach any target state in \((H^2_0(\Omega))^2 \times (L^2(\Omega))^2\) (resp. \((L^2(\Omega))^2 \times (H^{-1}(\Omega))^2\)). The controllability question for (3)-(5) hence becomes: Starting from rest at time \( t = 0 \), is it possible to reach all \(H^2_0(\Omega) \times H^2 \cap H^1_0(\Omega) \times L^2(\Omega) \times H^2_0(\Omega)\) (resp. \(L^2(\Omega) \times H^2_0(\Omega) \times H^{-1}(\Omega) \times L^2(\Omega)\)) in time \( t = T \) sufficiently large?
The strategy we adopt here is to prove some controllability results for the hyperbolic systems (3) and (5), extending the two-levels energy method introduced in [2]. Then, using transmutation techniques, we deduce controllability properties of (2) and (4).

To state our results, we recall the classical Geometric Control Conditions GCC (resp. GCC_b), which, according to [5], is a necessary and sufficient condition for the internal (resp. boundary) observability and controllability of one wave equation. We say that \( \omega \subset \Omega \) satisfies GCC (resp. \( \Gamma \subset \partial \Omega \) satisfies GCC_b) if every generalized geodesic traveling at speed one in \( \Omega \) meets \( \omega \) (resp. \( \Gamma \) on a non-diffraactive point) in finite time.

We shall make the following key assumptions:
(i) We have \((-\Delta + a)u, u)_{L^2(\Omega)} \geq \lambda_0 \|u\|^2_{L^2(\Omega)}\), for some \( \lambda_0 > 0 \), for all \( u \in L^2(\Omega) \). In the case where \( c = \text{Id} \) and \( a = 0 \), the best constant \( \lambda_0 \) is \( 1/C^2_p \), where \( C_p \) is the Poincaré’s constant of \( \Omega \).
(ii) We have \( p \geq 0 \) on \( \Omega \), \( |p| \geq \omega_p \) for some open subset \( \omega_p \subset \Omega \) and set \( p^+ := \|p\|_{L^\infty(\Omega)} \).
(iii) We have \( b \geq 0 \) on \( \Omega \), \( |b| > 0 \) on \( \partial \Omega \) and \( \{b_0 \geq 0 \} \supset \Gamma_b \) for some open subset \( \omega_b \subset \Omega \) (resp. \( \Gamma_b \subset \partial \Omega \)).

We shall also require that the operator \( A_b \) satisfies, for \( C > 0 \), \((A_b(v_1, v_2), (v_1, v_2)) \geq C(||v_1||_{H^1(\omega)}^2 + ||v_2||_{H^1(\omega)}^2)\) for all \((v_1, v_2) \in D(A_b)\). This is the case when assuming \( \sqrt{\delta} p^+ < \lambda_0 \).

**Theorem 2.1** (Wave-type systems). Suppose that (i) holds, that \( \omega_p \) satisfies GCC and that \( \omega_b \) (resp. \( \Gamma_b \)) satisfies GCC (resp. GCC_b). Then, there exists a constant \( \delta_* > 0 \) such that for all \( (\delta, p^+) \) satisfying \( \sqrt{\delta} p^+ < \delta_* \), there exists a time \( T > 0 \) such that for all \( T > T_* \), all \( p, b \) (resp. \( b_0 \)) satisfying (ii) and (iii), and all initial data \((u^0, u^1, u^2) \in H^1_0(\Omega) \times H^2(\Omega) \times L^2(\Omega)\) (resp. \((u^0, u^1) \in L^2(\Omega) \times H^1(\Omega) \times H^{-1}(\Omega) \times L^2(\Omega))\), there exists a control \( f \in L^2((0, T) \times \Omega) \) (resp. \( f \in L^2((0, T) \times \partial \Omega) \)) such that the solution of (3) (resp. (5)) satisfies \((u_1, u_2) \in L^2(0, T)\).

Another way to formulate this result is to say that, under the assumptions of Theorem 2.1, the reachable set at time \( T > T_* \), with zero initial data is exactly \( H^1_0(\Omega) \times H^2(\Omega) \times L^2(\Omega) \times H^1(\Omega) \times H^{-1}(\Omega) \times L^2(\Omega) \) in the case of \( L^2 \) internal control and \( L^2(\Omega) \times H^1_0(\Omega) \times H^{-1}(\Omega) \times L^2(\Omega) \) in the case of \( L^2 \) boundary control.

Some comments should be made about this result. First this is a generalization of the work [2] where the coupling coefficients considered have to satisfy \( p(x) \geq C > 0 \) for all \( x \in \Omega \). The geometric situations covered by Theorem 2.1 are richer, and include in particular several examples of coupling and control regions that do not intersect. Second, the coercivity assumption (i) for \(-\Delta + a \) together with the smallness assumption on \( \sqrt{\delta} p^+ \) seem to be only technical and inherent to the method we use here. Note by the way that this smallness assumption contains the coercivity assumption for \( A_b \), and allows to consider large \( p^+ \) or large \( \delta \) (providing that the other is small enough). Moreover, the control time \( T_* \) we obtain depends on all the parameters of the system, and not only the sets \( \omega_p \), \( \omega_b \) and \( \Gamma_b \) (as it is the case for a single wave equation). Finally, the fact that we consider twice the same elliptic operator \( \Delta_b \) is a key point in our proof and is likely that this result does not hold for waves with different speeds (see [2] for results with different speeds and different operators).

As a consequence of Theorem 2.1 and using transmutation techniques (due to [15, 11] for heat-type equations and to [13, 12] for Schrödinger-type equations), we can now state the associated results for Systems (2) and (4).

**Corollary 2.2** (Heat-type systems). Suppose that (i) holds, that \( \omega_p \) satisfies GCC and that \( \omega_b \) (resp. \( \Gamma_b \)) satisfies GCC (resp. GCC_b). Then, there exists a constant \( \delta_* > 0 \) such that for all \( (\delta, p^+) \) satisfying \( \sqrt{\delta} p^+ < \delta_* \), for all \( \theta \in (-\pi/2, \pi/2) \), for all \( p, b \) (resp. \( b_0 \)) satisfying (ii) and (iii), and all initial data \((u^0, u^1) \in \Omega - H^1(\Omega) \times H^{-1}(\Omega) \times L^2(\Omega)\) (resp. \((u^0, u^1) \in H^1(\Omega) \times L^2(\Omega))\), there exists a control \( f \in L^2((0, T) \times \partial \Omega) \) (resp. \( f \in L^2((0, T) \times \partial \Omega) \)) such that the solution of (2) (resp. (4)) satisfies \((u_1, u_2) \in L^2(0, T)\).

**Corollary 2.3** (Schrödinger-type systems). Under the assumptions of Corollary 2.2, the same null-controllability result holds for System (2) (resp. (4)) with \( \theta = \pm \pi/2 \), taking initial data \((u^0, u^1) \in L^2(\Omega) \times H^1_0(\Omega) \) (resp. \((u^0, u^1) \in H^1(\Omega) \times L^2(\Omega))\). Whether or not a general target in \( H^1(\Omega) \times L^2(\Omega) \) is reachable for (2) (resp. (4)) with \( \theta = \pm \pi/2 \) remains open.

### 3 Abstract setting and ingredients of proof

In this section, we describe the abstract setting (already used in [3]) in which we prove Theorem 2.1 for Systems (3)-(5), and define the appropriate spaces and operators. Let \( H \) be a Hilbert space and \((A, D(A))\) a selfadjoint positive operator on
Note that the operator $A$ is the multiplication by the function $\phi$ and a number $p$ such that $(A\phi, \phi)$ is positive and preserved for all $\phi \in H_k$. Hence, $A$ is self-adjoint on the space $H\times H$ endowed with the weighted inner product $(V, \bar{V})_k = (v_1, \bar{v}_1)_H + \delta(v_2, \bar{v}_2)_H$. Since we have $(A\phi, \phi)_k = (Av_1, v_1)_H + \delta(Av_2, v_2)_H + 2\delta(Pv_1, v_1)_H \geq (1 - \frac{p^2}{\lambda_0})(|v_1|^2_H + \delta|v_2|^2_H)$, we shall suppose that $p^2 < \lambda_0$, so that $A$ is coercive. Under this assumption, $(A^2 V, A^2 \bar{V})_k$ defines an inner product on $(H_k)^2$, equivalent to the natural one. Assuming that $P, P^* \in \mathcal{L}(H_k)$ and writing $H_k = (H_k^2)^2 \times H_{k-1}, k \in \mathbb{Z}$, the operator $A$ is an isomorphism from $H_k$ to $H_{k-1}$ and is skew-adjoint on $H_k$, equipped with the inner product $((U, V), (\bar{U}, \bar{V}))_H = (A_{\phi}^2 U, A_{\phi}^2 \bar{V})_k + (A_{\phi} V, A_{\phi} \bar{V})_k$. This is an inner product that is equivalent to the coercivity assumption for $A$, which is equivalent to the natural inner product of $H_k$. Hence, $A$ generates a group $e^{-\lambda t}$ on $H_k$, and the homogeneous problem (6) is well-posed in these spaces. An important feature of solutions $V(t)$ of System (6) is that all energies $E_k(t) = 1/2 \|V(t)\|^2_{(H_k)}$ are positive and preserved through time.

For this system, now studied in $H_k$, we shall observe only the state of the first component, i.e. $(u_1, u_1')$, and hence define an observation operator $B^* \in \mathcal{L}(H_k, H, Y)$, where $Y$ is a Hilbert space, standing for our observation space. This definition is sufficiently general to take into account both the boundary observation problem (taking $B^* \in \mathcal{L}(H_2, Y)$) and the internal observation problem (taking $B^* \in \mathcal{L}(H, Y)$). We assume that $B^*$ is an admissible observation for one equation:

$$\{ \begin{array}{ll} \text{For all } T > 0 \text{ there exists a constant } C > 0, \text{ such that all the solutions } \varphi \text{ of } \varphi'' + A\varphi = f \text{ satisfy } & \\
\int_0^T \|B^*(\varphi, \varphi')\|^2 dt \leq C \{e_1(\varphi(0)) + e_1(\varphi(T)) + \int_0^T e_1(\varphi(t))dt + \int_0^T \|\varphi''\|^2 dt\}. \end{array} \quad (A1)$$

Under this assumption, we have the following lemma.

**Lemma 3.1.** The operator $B^*$ is an admissible observation for (6). More precisely, for all $T > 0$, there exists a constant $C > 0$, such that all the solutions of (6) satisfy

$$\int_0^T \|B^*(v_1, v_1')\|^2 dt \leq C \{e_1(v_1(0)) + e_0(v_2(0))\}. \quad (7)$$

Note that only the $e_0$ energy level of the second component $v_2$ is necessary in this admissibility estimate. Hence, we cannot hope to observe the whole $H_k$ energy of $V$ and the best observability we can expect only involves $e_0(v_2)$. Our aim is now to prove this inverse inequality of (7). For this, we have to suppose some additional assumptions on the operators $P$ and $B^*$. Let us first precise Assumption (A2), related with the operator $P$:

$$\{ \begin{array}{ll} \text{We have } \|Pv\|^2_H \leq p^+(Pv, v)_H \text{ and there exists an operator } \Pi_P \in \mathcal{L}(H), \|\Pi_P\|_{\mathcal{L}(H)} = 1, & \\
\text{and a number } p^+ > 0 \text{ such that } & (Pv, v)_H \geq p^+ \|\Pi_Pv\|^2_H \forall \nu \in H. \end{array} \quad (A2)$$

Note that $p^+ \leq p^+ = \|P\|_{\mathcal{L}(H)}$ and that (A2) implies that the operators $P$ and $P^*$ are non-negative. In the applications to coupled wave equations, $P$ is the multiplication by the function $p$ and the operator $\Pi_P$ is the multiplication by the characteristic function $I_{\omega_p}$. Next, we shall suppose that a single equation is observable both by $B^*$ and by $\Pi_P$ in sufficiently large time:

$$\{ \begin{array}{ll} \exists T_0 > 0 \text{ such that for all } T > T_0 \text{ there exists a constant } C > 0, \text{ such that all solutions } \varphi \text{ of } \varphi'' + A\varphi = 0 & \\
\text{satisfy both } e_1(\varphi(0)) \leq C \int_0^T \|B^*(\varphi, \varphi')\|^2 dt, & e_1(\varphi(0)) \leq C \int_0^T \|\Pi_P\varphi\|^2 dt \end{array} \quad \text{(A3)}$$
In the context of Theorem 2.1, these observability assumptions are satisfied as soon as $\omega_p$ and $\omega_b$ satisfy GCC (resp. $\Gamma$ satisfies GCC$_b$). We can now state (without proof) the main result of this note.

**Theorem 3.2.** Suppose that Assumptions (A1)-(A3) hold. Then there exists a constant $\delta$, such that for all $\delta$, $p^+$ satisfying $\sqrt[\delta]{p^+} < \delta$, there exists a time $T$, such that for all $T > T$, there exists $C > 0$, such that for all $\mathcal{V}^0 \in \mathcal{H}_1$, the solution $\mathcal{V}(t) = e^{t\mathcal{A}}\mathcal{V}^0$ of (6) satisfies

$$e_1(v_1(0)) + e_0(v_2(0)) \leq C \int_0^T \|\mathcal{V}'(v_1,v_1')(t)\|_Y^2 dt.$$  

(8)

Applying the Hilbert Uniqueness Method (HUM) of [10], we deduce now controllability results for the adjoint system.

In this context, we have to define more precisely the observation operator. We shall treat two cases: First, $\mathcal{B}'(v_1,v_1') = B^y v'_1$ with $B^y \in \mathcal{L}(H,Y)$, corresponding to internal observability (with $Y = L^2(\Omega)$), and second $\mathcal{B}'(v_1,v_1') = B^v v_1$ with $B^v \in \mathcal{L}(H^2,Y)$, corresponding to boundary observability (with $Y = L^2(\partial\Omega)$). In both cases, we define the control operator $B$ as the adjoint of $B^*$, and the control problem reads, for a control function $f$ taking its values in $Y$,

$$\begin{cases}
  u''_1 + Au_1 + \delta Pu_2 = Bf \\
  u''_2 + Au_2 + \mathcal{P}^* u_1 = 0 \\
  (u_1, u_2, u'_1, u'_2)|_{t=0} = (u^0_1, u^0_2, u^1_1, u^1_2).
\end{cases}$$  

(9)

This is an abstract version of (3)-(5). Note that under this form, System (9) not only contains (3)-(5), but also locally coupled systems of plate equations, with a distributed or a boundary control.

**First case:** $\mathcal{B}'(v_1,v_1') = B^y v'_1$ with $B^y \in \mathcal{L}(H,Y)$. In this case, $B \in \mathcal{L}(Y,H)$ and the control problem (9) is well-posed in $\mathcal{H}_1$ for $f \in L^2(0,T;Y)$. In this setting, we first deduce from (8) the following other observability estimate for solutions $W$ of (6) in $\mathcal{H}_0$: $e_0(v_1(0)) + e_1(v_2(0)) \leq C \int_0^T \|\mathcal{B}'(v_1,v_1')(t)\|_Y^2 dt$. The internal control result of Theorem 2.1 is then a direct consequence of the HUM since Assumptions (A1)-(A3) are satisfied in this application.

**Second case:** $\mathcal{B}'(v_1,v_1') = B^v v_1$ with $B^v \in \mathcal{L}(H^2,Y)$. As a consequence of the admissibility inequality (7), System (9) is well-posed in $\mathcal{H}_0$ in the sense of transposition solutions. In this setting, the boundary control result of Theorem 2.1 is a direct consequence of the HUM and Theorem 3.2 since Assumptions (A1)-(A3) are satisfied in this application.
