ABSTRACT
In this paper, we present a frequency tunable antenna suitable for Digital Video Broadcasting Handheld applications. Due to the narrow operating frequency band of the antenna derived from a monopole coupled loop antenna, a tuning system has been proposed to sweep the narrow band on a large frequency range in order to cover the DVB-H frequency bandwidth [470-702] MHz. We provide results of this antenna mounted on a circuit board simulating a terminal handset.

KEYWORDS — Monopole coupled loop antenna, frequency tunable antenna, varactor diode loading, size reduction.

1. INTRODUCTION
With the development of handled communication services, such as Digital Video Broadcast-Handled (DVB-H), the needs for small and broadband antennas are ever demanding. The major challenges are the very broadband frequency range [470-702] MHz defined in the European standard and the necessity to embed antenna working in UHF into mobile handset. Several methods are proposed to solve these problems. In [1-3], broadband antennas are proposed for Digital Broadcast applications and are integrated, for example, in folder type mobile phone or in USB stick. For these antennas, impedance, gain and efficiency are compliant with the specifications. The second method to cover the frequency range of such broadband applications uses frequency tunable antennas. The basic antenna is then a narrow band one and the implementation of active devices introduces a frequency tunable ability. From a system point of view, it provides frequency selectable function which improves the signal to noise ratio. In [4-5], varactor diodes have been associated to PIFA or meander antenna and radiation patterns like S\textsubscript{11} demonstrate antenna's performances. We also
notice in [9-10] that for such application the behavior of the antenna must be provided with the inclusion of the circuit board simulating the mobile handset. In this paper and based on [6-7], we propose a frequency tunable antenna constructed with a varactor diode and a modified Monopole Coupled Loop Antenna (MCLA).

In the first part of this study, we introduce the modified MCLA and we give antenna’s behavior. For practical purpose, in this first part the antenna is placed above a limited ground plane (300 mm x 300 mm). This antenna provides a narrow band operating frequency band (around 790 MHz). In the second part, we present an evolution of this antenna where the radiating element is associated to a parallel ground plane. This configuration simulates the behavior of the radiating element in the presence of mobile handset’s circuit board. To cover the large frequency of DVB-H application, we investigate the ability to sweep the narrow band by introducing a frequency tunable system. The tuning method presented is based on locating a varactor diode directly in the antenna in order to continuously control the operating frequency with a DC bias voltage. As a result, a desirable frequency in a broadband frequency range covering [470-702] MHz is achieved.

2 A NARROW BAND ANTENNA DERIVED FROM MONOPOLE COUPLED LOOP ANTENNA (MCLA)

In Figure 1, we show the geometry of a MCLA loaded with inductor which is the basis of our work. In [6], we have demonstrated that a modified antenna with an open circuit provides size reduction. Unfortunately, this technique did not allow antenna’s size compatible with mobile terminal’s dimensions. It means that additional techniques should be inserted to achieve this goal.

![Figure 1: Geometry of the MCLA](image)

As a technique for reducing the volume of this antenna, we introduce change in line width on the half loop part [8] and we associate the printed antenna to a high permittivity substrate (i.e. ceramic). An overview of the antenna structure with its main dimensions is shown in figure 2. It is built on a 0.8mm thick dielectric substrate (Neltec NY9300, $\varepsilon_r=3$) associated to a ceramic substrate ($\varepsilon_r=20$). For the preliminary studies, the antenna is placed above a limited ground plane.
If we compare Figure 1 and Figure 2, it is easy to recognize that the circular half loop becomes a square one. We also notice that the method to feed the rectangular loop is still an electromagnetic coupling method with a small monopole with a specific P shape. As we mention at the beginning of this paragraph, an open circuit in the right side of the square loop provides a decisive contribution to size reduction.

A prototype was studied and manufactured around 790 MHz. Figure 3 shows the measured and simulated return losses. The simulated results are obtained using HFSS® Software (High Frequency Structure Simulator) and we notice a good agreement between the theory and the measurement. The frequency bandwidth is close to 10 MHz which is suitable for DVB-H reception, since one channel in a bandwidth of 8MHz is received at a time.

3 FREQUENCY TUNABLE ANTENNA FOR DVB-H

To evolve through the mobile terminal applications, we modify the ground plane configuration. As depicted in Figure 4, the antenna described in Figure 2 is associated to a parallel ground plane and optimized in order to take into account the shape of the parallel ground plane.
Figure 4: Overview of the frequency tunable antenna with the circuit board simulating the mobile circuit board (a) and a zoom of the antenna with the DC bias circuit.

Then, we include a varactor diode on the optimised square loop to control the resonant frequency with a DC bias voltage. As a function of this DC bias voltage, the varactor diode is associated with an inductor in order to realize a tuning inductor which changes the equivalent electrical length of the square loop. This mechanism could be used to slightly tune the resonant frequency of the antenna.

The varactor component used is a MACOM MA4ST2200 diode. The equivalent circuit proposed by the vendor is a series RLC circuit with a parallel capacitance (Figure 5). $C_s$ is the tunable capacitor. The varactor has been characterized using a vector network analyser and then the equivalent circuit has been obtained through a de-embedding process.

Figure 5: Equivalent circuit models of the varactor diode

Performances of this tunable antenna have been investigated using HFSS® software, substituting the diode by its equivalent circuit (Figure 5).

In order to keep an operating frequency close to 470 MHz when the DC bias voltage is equal to zero, the parameters of the antenna depicted in Figure 4 have been optimized with the corresponding diode equivalent circuit characteristics. The bias circuit used to carry a DC control voltage to the varactor without interfering with the high frequencies currents is presented in Figure 4b. The DC voltage is isolated from RF signal by a Radio Frequency choke of 2200nH, a series resistance of $5k\Omega$ and one chip capacitor of $5nF$.

The antenna performances have been computed for different DC control voltage values. Figures 6a and 6b show the measured and the theoretical return loss characteristics for a few voltage values. The
frequency band is controlled by adjusting the variable capacitance of the varactor diode with the DC bias voltage. The range of this DC bias voltage is from 0V to 2V and is compatible with the output voltage of a mobile’s battery.

![Graphs showing theoretical and measured return losses](image)

**Figure 6**: Theoretical (a) and measured (b) return losses (antenna fig 4)

As shown in Figure 7, the antenna covers the [470-702] MHz frequency range which corresponds to a 39.5% relative -10 dB bandwidth. For each operating frequency, the corresponding instantaneous bandwidth is more than 10 MHz. We can also notice a good agreement between theory and measurements.

![Graphs showing radiation patterns](image)

(a) DC voltage : 0V, f= 470 MHz (-) Eθ in YZ plane

(b) DC voltage : 0V, f= 470 MHz (...)Eφ and and Eθ (-- in XZ plane

(c) DC voltage : 1.5V, f = 620 MHz (-)Eθ in YZ plane

(d) DC voltage : 1.5V, f=620 MHz (...)Eφ and and Eθ (-- in XZ plane
Radiation properties were also computed for different DC bias voltage and the normalized radiation patterns are represented in Figure 7. For YZ plane (Fig 7 a, c, e), we obtain a dissymmetric shape of radiation pattern due to the specific position of the radiating element on the circuit board. To complete these results, we add that the theoretical gain starts from -9dBi at 470 MHz up to -2.5 dBi at 702 MHz. Theses gains are compliant with the DVB-H specifications.

4 CONCLUSION

A varactor tuned antenna has been designed and realized. The aim of this study is to provide a simple technique to sweep the instantaneous bandwidth of a radiating element from 470 to 702 MHz. The main advantage of this tunable antenna proposed for DVB-H application is its suitability for mobile terminals. The effectiveness of the tuning ability has been demonstrated and measurements are found to be in good agreement with theory for the return loss. For completeness, other important requirements such as DC power consumption and DC bias voltage range compatible with the output voltage of a mobile’s battery have been considered.
