ON THE EXTERNAL BRANCHES OF COALESCENTS WITH MULTIPLE COLLISIONS

J.-S. DHERSIN and M. MÖHLE

February 24, 2013

Abstract

A recursion for the joint moments of the external branch lengths for coalescents with multiple collisions (Λ-coalescents) is provided. This recursion is used to derive asymptotic results as the sample size $n$ tends to infinity for the joint moments of the external branch lengths and for the moments of the total external branch length of the Bolthausen–Sznitman coalescent. These asymptotic results are based on a differential equation approach, which is as well useful to obtain exact solutions for the joint moments of the external branch lengths for the Bolthausen–Sznitman coalescent. The results for example show that the lengths of two randomly chosen external branches are positively correlated for the Bolthausen–Sznitman coalescent, whereas they are negatively correlated for the Kingman coalescent provided that $n \geq 4$.

1 Introduction and main results

Let $\Pi = (\Pi_t)_{t \geq 0}$ be a coalescent process with multiple collisions (Λ-coalescent). For fundamental information on Λ-coalescents we refer the reader to [23] and [24]. For $n \in \mathbb{N} := \{1, 2, \ldots\}$ we denote with $\Pi^{(n)} = (\Pi^{(n)}_t)_{t \geq 0}$ the coalescent process restricted to $[n] := \{1, \ldots, n\}$. Note that $\Pi^{(n)}$ is Markovian with state space $\mathcal{E}_n$, the set of all equivalence relations (partitions) on $[n]$. For $\xi \in \mathcal{E}_n$ we write $|\xi|$ for the number of equivalence classes (blocks) of $\xi$. For $m \in \{1, \ldots, n - 1\}$ let $g_{nm}$ be the rate at which the block counting process $N^{(n)} := (N^{(n)}_t)_{t \geq 0} := (|\Pi^{(n)}_t|)_{t \geq 0}$ jumps at its first jump time from $n$ to $m$. It is well known (see, for example, [21, Eq. (13)]) that

$$g_{nm} = \binom{n}{m-1} \int_{[0,1]} x^{n-m-1}(1-x)^{m-1} \Lambda(dx)$$

for all $n, m \in \mathbb{N}$ with $m < n$. We furthermore introduce the total rates

$$g_n := \sum_{m=1}^{n-1} g_{nm} = \int_{[0,1]} \frac{1 - (1-x)^n - nx(1-x)^{n-1}}{x^2} \Lambda(dx), \quad n \in \mathbb{N}. \quad (2)$$

We are interested in the external branches of the restricted coalescent process $\Pi^{(n)}$. More precisely, for $n \in \mathbb{N}$ and $i \in \{1, \ldots, n\}$ let $\tau_{n,i} := \inf\{t > 0 : \{i\} \text{ is a singleton block of } \Pi^{(n)}_t\}$ denote the length of the $i$th external branch of the restricted coalescent $\Pi^{(n)}$. Note that $\tau_{1,1} = 0$. Our first main result (Theorem 1.1) provides a general recursion for the joint moments

$$\mu_n(k_1, \ldots, k_j) := \mathbb{E}(\tau_{n,1}^{k_1} \cdots \tau_{n,j}^{k_j}), \quad j \in \{1, \ldots, n\}, k_1, \ldots, k_j \in \mathbb{N}_0 := \{0, 1, \ldots\}, \quad (3)$$

of the external branch lengths. The proof of Theorem 1.1 is provided in Section 2.

**Theorem 1.1 (Recursion for the joint moments of the external branch lengths)**

For all \( n \geq 2, \ j \in \{1, \ldots, n\} \) and \( k = (k_1, \ldots, k_j) \in \mathbb{N}^j \) the joint moments \( \mu_n(k) := \mathbb{E}(\tau_{n,1}^{k_1} \cdots \tau_{n,j}^{k_j}) \) of the lengths \( \tau_{n,1}, \ldots, \tau_{n,n} \) of the external branches of a \( \Lambda \)-coalescent \( \Pi^{(n)} \) satisfy the recursion

\[
\mu_n(k) = \frac{1}{g_n} \sum_{i=1}^{j} k_i \mu_n(k - e_i) + \sum_{m=j+1}^{n-1} p_{nm} \frac{(m-1)_{j}}{(n)_{j}} \mu_m(k), \quad (4)
\]

where \( e_i, i \in \{1, \ldots, j\} \), denotes the \( i \)-th unit vector in \( \mathbb{R}^j \), \( p_{nm} := g_{nm}/g_n \) and \( g_{nm} \) and \( g_n \) are defined via \([4]\) and \([3]\).

**Remarks.** The recursion (4) works as follows. Let us call \( d := k_1 + \cdots + k_j \) the order (or degree) of the moment \( \mu_n(k_1, \ldots, k_j) \). Provided that all the moments of order \( d - 1 \) are already known, (4) is a recursion on \( n \) for the joint moments of order \( d \), which can be solved iteratively. So one starts with \( d = 1 \) (and hence \( j = 1 \)), in which case (4) reduces to \( \mu_n(1) = 1/g_n + \sum_{m=2}^{n-1} p_{nm}(m-1/n)\mu_m(1) \), \( n \geq 2 \). Since \( \mu_2(1) = \mathbb{E}(\tau_{2,1}) = 1/g_2 = 1/\Lambda([0,1]) \), this recursion determines the moments of order \( 1 \) completely. Now choose \( d = 2 \) in (4) leading to a recursion for the second order moments. Iteratively, one can move to higher orders. Note that for \( j = 2 \) and \( k_1 = k_2 = 1 \) the recursion (4) reduces to

\[
\mathbb{E}(\tau_{n,1} \tau_{n,2}) = \frac{2}{g_n} \mathbb{E}(\tau_{n,1}) + \sum_{m=2}^{n-1} p_{nm} \frac{(m-1)}{(n)} \mathbb{E}(\tau_{m,1} \tau_{m,2}), \quad n \in \{2, 3, \ldots\}. \quad (5)
\]

Note that Theorem 1.1 holds for arbitrary \( \Lambda \)-coalescents. For particular \( \Lambda \)-coalescents the recursion (4) can be used to derive exact solutions and asymptotic expansions for the joint moments of the lengths of the external branches. In the following we briefly discuss the star-shaped coalescent and the Kingman coalescent. Afterwards we intensively study the Bolthausen–Sznitman coalescent. For related results on external branches for beta-coalescents we refer the reader to \([8]\), \([9]\) and \([19]\).

**Example.** (Star-shaped coalescent) For the star-shaped coalescent, where \( \Lambda \) is the Dirac measure at 1, the time \( T_n \) of the first jump of \( \Pi^{(n)} \) is exponentially distributed with parameter \( g_n = 1 \), \( n \in \{2, 3, \ldots\} \). Furthermore, \( p_{nm} = \delta_{m,1} \) for \( n, m \in \mathbb{N} \) with \( m < n \). Thus, (4) reduces to \( \mu_n(k) = \sum_{i=1}^{j} k_i \mu_n(k - e_i) \) with solution \( \mu_n(k) = (k_1 + \cdots + k_j)! \), which is obviously correct, since \( \tau_{n,i} = T_n \) for all \( i \in \{1, \ldots, n\} \) and, therefore, \( \mu_n(k) = \mathbb{E}(T_n^{k_1 + \cdots + k_j}) = (k_1 + \cdots + k_j)! \), \( n \geq 2, j \in \{1, \ldots, n\} \), \( k_1, \ldots, k_j \in \mathbb{N} \).

**Example.** (Kingman coalescent) For the Kingman coalescent \([20]\), where \( \Lambda \) is the Dirac measure at 0, the time \( T_n \) of the first jump of \( \Pi^{(n)} \) is exponentially distributed with parameter \( g_n = n(n-1)/2, n \in \{2, 3, \ldots\} \). Furthermore, \( p_{nm} = \delta_{m,n-1} \) for \( m, n \in \mathbb{N} \) with \( m < n \). Caliebe et al. \([6]\) Theorem 1] verified that \( n\tau_{n,1} \to Z \) in distribution as \( n \to \infty \), where \( Z \) has density \( x \to 8/(2+x)^3, x \geq 0 \). Janson and Kersting \([17]\) Theorem 1] showed that the total external branch length \( T_n^{external} := \sum_{i=1}^{n} \tau_{n,i} \) satisfies \( (1/2)\sqrt{n/(\log n)}(T_n^{external} - 2) \to N(0,1) \) in distribution as \( n \to \infty \). We are instead interested here in the moments of \( \tau_{n,1} \). The recursion (4) for \( j = 1 \) reduces to

\[
\mu_n(k) = \frac{2k}{n(n-1)} \mu_n(k-1) + \frac{n-2}{n} \mu_{n-1}(k), \quad n \in \{2, 3, \ldots\}, k \in \mathbb{N}.
\]
Rewriting this recursion in terms of \( a_n(k) := n(n - 1)\mu_n(k) \) yields \( a_n(k) = 2k\mu_n(k - 1) + a_{n-1}(k) \), \( n \in \{2, 3, \ldots\} \), \( k \in \mathbb{N} \), with solution \( a_n(k) = 2k\sum_{m=2}^{n}\mu_m(k-1) \). Thus,

\[
\mu_n(k) = \frac{2k}{n(n-1)}\sum_{m=2}^{n}\mu_m(k-1), \quad n \in \{2, 3, \ldots\}, k \in \mathbb{N}.
\]

The first two moments are therefore \( \mathbb{E}(\tau_{n,1}) = \mu_n(1) = 2/(n(n-1))\sum_{m=2}^{1} 1 = 2/n \) and

\[
\mathbb{E}(\tau_{n,1}^2) = \mu_n(2) = \frac{4}{n(n-1)}\sum_{m=2}^{n}\frac{2}{m} = \frac{8(h_n - 1)}{n(n-1)} = 8\frac{\log n}{n^2} + 8\frac{(\gamma - 1)}{n^2} + O\left(\frac{\log n}{n^3}\right),
\]

where \( \gamma \approx 0.577216 \) denotes the Euler constant and \( h_n := \sum_{i=1}^{n} 1/i \) the \( n \)-th harmonic number, \( n \in \mathbb{N} \). Note that these results are in agreement with those of Caliebe et al. [4, Eq. (2)] and Janson and Kersting [17, p. 2205]. For the third moment we obtain

\[
\mu_n(3) = \frac{6}{n(n-1)}\sum_{m=2}^{n}8(h_m - 1/m) = \frac{48}{n(n-1)}\sum_{m=2}^{n}h_m - 1/m = 48\frac{\gamma - 1}{n} + O\left(\frac{1}{n^{3/2}}\right),
\]

Since \( h_{m+1} - h_m = 1/(m+1) \), the last sum simplifies considerably to

\[
\sum_{m=2}^{n} \frac{h_m - 1}{m(m-1)} = \sum_{m=2}^{n} \left( \frac{h_m}{m-1} - \frac{h_m}{m} - \frac{1}{m(m-1)} \right) = \sum_{m=1}^{n-2} \frac{h_{m+1}}{m} - \sum_{m=2}^{n} \frac{h_m}{m} - \left( \frac{1}{m-1} \right)
\]

\[
= h_2 + \sum_{m=2}^{n-1} \frac{1}{m(m-1)} - \frac{h_n}{n-1} + \frac{1}{n} = 1 - \frac{h_n}{n},
\]

Thus, the third moment of \( \tau_{n,1} \) is

\[
\mathbb{E}(\tau_{n,1}^3) = \mu_n(3) = \frac{48}{n(n-1)}\left(1 - \frac{h_n}{n}\right) = \frac{48}{n^2} - 48\frac{\log n}{n^3} + O\left(\frac{1}{n^3}\right).
\]

For the fourth moment we obtain

\[
\mathbb{E}(\tau_{n,1}^4) = \mu_n(4) = \frac{8}{n(n-1)}\sum_{m=2}^{n}\mu_m(3) = \frac{384}{n(n-1)}\sum_{m=2}^{n} \frac{1 - h_m/m}{m(m-1)},
\]

a formula which does not seem to simplify much further. One may also introduce the generating functions \( g_k(t) := \sum_{n=2}^{\infty}\mu_n(k) t^n \), \( k \in \mathbb{N} \), \( |t| < 1 \). For all \( k \geq 2 \) we have

\[
t^2g_k''(t) = \sum_{n=2}^{\infty}n(n-1)\mu_n(k) t^n = \sum_{n=2}^{\infty}2k\sum_{m=2}^{n}\mu_m(k-1) t^n
\]

\[
= 2k\sum_{m=2}^{\infty}\mu_m(k-1) t^m \sum_{m=n}^{\infty} t^{n-m} = \frac{2k}{1-t}g_{k-1}(t),
\]

so these generating functions satisfy the recursion

\[
g_k(t) = 2k\int_{0}^{t} \int_{0}^{s} \frac{g_{k-1}(u)}{u^2(1-u)} \, du \, ds, \quad k \geq 2, 0 \leq t < 1,
\]
with initial function \( g_1(t) = \sum_{n=2}^{\infty} (2/n) t^n = -2t - 2 \log(1 - t) \). Using this recursion, \( g_k(t) \) can be computed iteratively, however, the expressions become quite involved with increasing \( k \). For example, \( g_2(t) = 8t - 4(1 - t) \log^2(1 - t) - 8(1 - t) \text{Li}_2(t), \ |t| < 1, \) where \( \text{Li}_2(t) := -\int_0^t (\log(1 - x))/x \ dx = \sum_{k=1}^{\infty} t^k/k^2 \) denotes the dilogarithm function. In principle higher order moments and as well joint moments can be calculated analogously, however, the expressions become more and more nasty with increasing order. In the following we exemplary derive an exact formula for \( \mu_n(1, 1) = E(\tau_{n, 1} \tau_{n, 2}) \). The recursion \( \mu_n(1, 1) = \frac{2}{g_n}\mu_n(1) + \frac{(n - 2)^2}{n^2(n - 1)} \mu_{n-1}(1, 1) = \frac{8}{n^2(n - 1)} + \frac{(n - 2)(n - 3)}{n(n - 1)} \mu_{n-1}(1, 1), \ n \geq 2. \)

It is readily checked by induction on \( n \) that this recursion is solved by \( \mu_2(1, 1) = 2 \) and

\[
\mu_n(1, 1) = \frac{4(n^2 - 5n + 4h_n)}{n(n - 1)^2(n - 2)}, \quad n \in \{3, 4, \ldots\}.
\]

In particular, \( \mu_n(1, 1) = 4/n^2 - 4/n^3 + O((\log n)/n^4), n \to \infty \). Moreover, \( \text{Cov}(\tau_{n, 1}, \tau_{n, 2}) = \mu_n(1, 1) - (\mu_n(1))^2 = 4(n^2 - 5n + 4h_n)/(n(n - 1)^2(n - 2)) - 4/n^2 < 0 \) for all \( n \geq 4 \). Thus, for the Kingman coalescent, the lengths of two randomly chosen external branches are (slightly) negatively correlated for all \( n \geq 4 \). We have used the derived formulas to compute the following table.

\( n \to \infty \)

| \( \frac{2}{n} \) | \( \frac{4}{n^2} - \frac{4}{n^3} + O(\frac{\log n}{n^4}) \) | \( -\frac{4}{n^2} + O(\frac{\log n}{n^4}) \) |

Table 1: Covariance of \( \tau_{n, 1} \) and \( \tau_{n, 2} \) for the Kingman coalescent.

In the following we focus on the Bolthausen–Sznitman coalescent [5], where \( \Lambda \) is the uniform distribution on \([0, 1]\). Our second main result (Theorem 1.2) provides the asymptotics of all the joint moments of the external branch lengths for the Bolthausen–Sznitman coalescent.

**Theorem 1.2 (Asymptotics of the joint moments of the external branch lengths)**

For the Bolthausen–Sznitman coalescent, the joint moments \( \mu_n(k) := E(\tau_{n, 1}^{k_1} \cdots \tau_{n, j}^{k_j}), j \in \mathbb{N}, k = (k_1, \ldots, k_j) \in \mathbb{N}_0^j, \) of the lengths \( \tau_{n, 1}, \ldots, \tau_{n, n} \) of the external branches satisfy

\[
\mu_n(k) \sim \frac{k_1! \cdots k_j!}{\log^{k_1+\cdots+k_j} n}, \quad n \to \infty.
\]

**Remark.** For \( j = 2 \) and \( k_1 = k_2 = 1 \) Eq. (6) implies that \( E(\tau_{n, 1}\tau_{n, 2}) = \mu_n(1, 1) \sim 1/\log^2 n \sim (\mu_n(1))^2 \) as \( n \to \infty \), which does not provide much information on the covariance \( \text{Cov}(\tau_{n, 1}, \tau_{n, 2}) = \mu_n(1, 1) - (\mu_n(1))^2 \). With some more effort (see Corollary 3.2 and the remark thereafter) exact solutions for \( E(\tau_{n, 1}) \) and \( E(\tau_{n, 1}\tau_{n, 2}) \) are obtained and it follows that \( \tau_{n, 1} \) and \( \tau_{n, 2} \) are positively correlated for all \( n \geq 2 \), in contrast to the situation for the Kingman coalescent, where \( \tau_{n, 1} \) and \( \tau_{n, 2} \) are slightly negatively correlated for all \( n \geq 4 \).
The following two corollaries are a direct consequence of Theorem 1.2.

**Corollary 1.3 (Weak limiting behavior of the external branch lengths)**

For the Bolthausen–Sznitman coalescent, $(\log n)(\tau_{n,1}, \ldots, \tau_{n,n}, 0, 0, \ldots) \to (\tau_1, \tau_2, \ldots)$ in distribution as $n \to \infty$, where $\tau_1, \tau_2, \ldots$ are independent and all exponentially distributed with parameter $1$.

The following result concerns the asymptotics of the total external branch length $L_{n,\text{external}} := \sum_{i=1}^{n} \tau_{n,i}$ of the Bolthausen–Sznitman coalescent.

**Corollary 1.4 (Asymptotics of the total external branch length)**

Fix $k \in \mathbb{N}$. For the Bolthausen–Sznitman coalescent, the $k$th moment of $L_{n,\text{external}}$ satisfies

$$E((L_{n,\text{external}})^k) \sim \frac{n^k}{\log n}, \quad n \to \infty. \quad (7)$$

In particular, $\frac{\log n}{n} L_{n,\text{external}} \to 1$ in probability as $n \to \infty$.

The moments of $L_{n,\text{external}}$ do not provide much information on the distributional limiting behavior of $L_{n,\text{external}}$ as $n \to \infty$. Let $L_n$ denote the total branch length (the sum of the lengths of all branches) of the Bolthausen–Sznitman $n$-coalescent. Kersting et al. [18, Theorem 1.1] recently showed that the internal branch length $L_{n,\text{internal}} := L_n - L_{n,\text{external}}$ satisfies

$$\frac{\log^2 n}{n} L_{n,\text{internal}} \to 1$$

in probability. Combining this result with [10, Theorem 5.2] it follows that (see [18, Corollary 1.2])

$$\frac{\log^2 n}{n} L_{n,\text{external}} - \log n - \log \log n \to L - 1 \quad (8)$$

in distribution as $n \to \infty$, where $L$ is a 1-stable random variable with characteristic function $t \mapsto \exp(it \log |t| - \pi |t|/2), \; t \in \mathbb{R}$.

**Remark.** The same scaling and, except for the additional shift $-1$ on the right hand side in (8), the same limiting law as in (8) is known for the number of cuts needed to isolate the root of a random recursive tree ([11], [16]). Essentially the same scaling and convergence result has been obtained for random records and cuttings in binary search trees by Holmgren [13, Theorem 1.1] and more generally in split trees (Holmgren [13, Theorem 1.1] and [15, Theorem 1.1]) introduced by Devroye [7]. The logarithmic height of the involved trees seems to be one of the main sources for the occurrence of such scalings and of 1-stable limiting laws. To the best of the authors knowledge the distributional limiting behavior of $L_{n,\text{internal}}$, properly centered and scaled, is so far unknown for the Bolthausen–Sznitman coalescent.

2 Proof of Theorem 1.1

Let $T = T_n$ denote the time of the first jump of the block counting process $N^{(n)}$ and let $I = I_n$ denote the state of $N^{(n)}$ at its first jump. Note that $T$ and $I$ are independent, $T$ is exponentially distributed
with parameter \( g_n \) and \( p_{nm} := \mathbb{P}(I = m) = g_{nm}/g_n, m \in \{1, \ldots, n - 1\} \). For \( i \in \{1, \ldots, n\} \) and \( h > 0 \) define \( \tau'_i := \tau_{ni} - h \land T \). By the Markov property, for \( h \to 0 \),

\[
\mathbb{E}(\tau'_{i1} \cdots \tau'_{i,j} 1_{\{T > h\}}) = \mathbb{E}((\tau'_i + h)^{k_1} \cdots (\tau'_j + h)^{k_j} 1_{\{T > h\}})
\]

\[
= \mathbb{E}(\tau'_{i1} \cdots \tau'_{i,j}) \mathbb{P}(T > h) + h \sum_{i=1}^{j} \kappa_i \mathbb{E}(\tau'_{i1} \cdots \tau'_{n,i-1} \tau'_{n,i} \cdots \tau'_{n,j}) + o(h).
\]

Also for \( h \to 0 \),

\[
\mathbb{E}(\tau'_{m1} \cdots \tau'_{m,j} 1_{\{T \leq h\}}) = \mathbb{E}((\tau'_{m1} + T)^{k_1} \cdots (\tau'_{m,j} + T)^{k_j} 1_{\{T \leq h\}}) = \mathbb{E}((\tau'_{m1})^{k_1} \cdots (\tau'_{m,j})^{k_j} 1_{\{T \leq h\}}) + o(h).
\]

Now at time \( T \) either the event \( A := \{ \text{one of the individuals 1 to } j \text{ is involved in the first collision} \} \) occurs, in which case \( \tau'_i = 0 \) for some \( i \in \{1, \ldots, j\} \), and the above expectation vanishes since \( k_1, \ldots, k_j > 0 \), or none of these \( j \) individuals is involved in the first collision. Then, by the strong Markov property,

\[
\mathbb{E}((\tau'_{m1})^{k_1} \cdots (\tau'_{m,j})^{k_j} 1_{\{T \leq h, I = m, A^c\}}) = \mathbb{E}(\tau'_{m1} \cdots \tau'_{m,j}) \mathbb{P}(T \leq h, I = m, A^c),
\]

where \( A^c \) denotes the complement of \( A \). Adding both expectations yields

\[
\mathbb{E}(\tau'_{m1} \cdots \tau'_{m,j}) = \mathbb{E}(\tau'_{m1} \cdots \tau'_{m,j}) \mathbb{P}(T > h) + h \sum_{i=1}^{j} \kappa_i \mathbb{E}(\tau'_{m1} \cdots \tau'_{n,i-1} \tau'_{n,i} \cdots \tau'_{n,j})
\]

\[
+ \sum_{m=j+1}^{n-1} \mathbb{E}(\tau'_{m1} \cdots \tau'_{m,j}) \mathbb{P}(T \leq h) \mathbb{P}(I = m) \frac{(m-1)!}{(n-1)!} + o(h).
\]

Collecting both terms involving \( \mathbb{E}(\tau'_{m1} \cdots \tau'_{m,j}) \) on the left hand side and letting \( h \to 0 \) gives the claim, since \( \mathbb{P}(T \leq h) = 1 - e^{-gnh} \sim g_nh \) as \( h \to 0 \). \( \square \)

3 Differential equations approach

A differential equations approach is provided, which is used in the proof of Theorem 2. This approach furthermore yields for example an exact expression for \( \mathbb{E}(\tau_{n1} \tau_{n2}) \) in terms of Stirling numbers (see Corollary 3.2). Let \( D := \{ z \in \mathbb{C} : |z| < 1 \} \) denote the open unit disc in the complex plane. For \( j \in \mathbb{N} \) and \( k = (k_1, \ldots, k_j) \in \mathbb{N}^j_0 \) define the generating function

\[
f_k(z) := \sum_{n=j}^{\infty} \mathbb{E}(\tau'_{n1} \cdots \tau'_{n,j}) z^{n-1} = \sum_{n=j}^{\infty} a_n z^{n-1}, \quad z \in D,
\]

where, for \( n \geq j \), we use the abbreviation \( a_n := \mu_n(k) := \mathbb{E}(\tau'_{n1} \cdots \tau'_{n,j}) \) for convenience. Note that, due to the natural coupling property of \( n \)-coalescents, the sequence \( (a_n)_{n \geq j} \) is non-increasing. Thus, \( f_k \) and all its derivatives \( f'_k, f''_k, \ldots \) are analytic functions on \( D \). In order to state the following result it is convenient to introduce \( L(z) := -\log(1 - z), \ z \in D, \) and to define the functions \( g_k : D \to \mathbb{C}, \)

\[
k = (k_1, \ldots, k_j) \in \mathbb{N}^j, \text{ via } g_1(z) := z/(1 - z) \text{ and }
\]

\[
g_k(z) := \sum_{i=1}^{j} k_i f_k^{(j-1)}(z) \quad (9)
\]
for all \( z \in D \) and all \( k = (k_1, \ldots, k_j) \in \mathbb{N}^j \) satisfying \( k_1 + \cdots + k_j > 1 \), where \( e_i, i \in \{1, \ldots, j\} \), denotes the \( i \)th unit vector in \( \mathbb{R}^j \).

**Lemma 3.1** For the Bolthausen–Sznitman coalescent, the function \( f_k, k = (k_1, \ldots, k_j) \in \mathbb{N}^j \), satisfies the differential equation

\[
\frac{d}{dz}((L(z))^{j-1} f_k^{(j-1)}(z)) = \frac{(L(z))^{j-2}}{1-z} g_k(z), \quad z \in D \setminus \{0\},
\]

with solution

\[
f_k^{(j-1)}(z) = \frac{1}{(L(z))^{j-1}} \int_0^z \frac{1}{1-t} (L(t))^{j-2} g_k(t) \, dt, \quad z \in D \setminus \{0\}.
\]

In particular,

\[
f_1(z) = \int_0^z \frac{t}{(1-t)^2 L(t)} \, dt \quad \text{and} \quad f_{1,1}(z) = \frac{2}{L(z)} \int_0^z \frac{t}{(1-t)^3 L(t)} \, dt, \quad z \in D \setminus \{0\}.
\]

**Proof.** For the Bolthausen–Sznitman coalescent, \( g_{nm} = n/((n-m)(n-m+1)), m \in \{1, \ldots, n-1\} \) and \( g_n = n-1, n \in \mathbb{N} \). Thus, \( p_{nm} := g_{nm}/g_n = n/((n-1)(n-m)(n-m+1)), m, n \in \mathbb{N} \) with \( m < n \). Fix \( j \in \mathbb{N} \) and \( k = (k_1, \ldots, k_j) \in \mathbb{N}^j \) and, for \( n \in \mathbb{N} \), define \( a_n := \mu_n(k) \) for convenience. For \( n \geq \max(2, j) \) the recursion (13) reads

\[
a_n = q_n + \sum_{m=j+1}^{n-1} p_{nm} \frac{m-1}{n} a_m = q_n + \frac{n}{(n-1)n} \sum_{m=j+1}^{n-1} \frac{m-1}{n-m(n-m+1)} a_m,
\]

where \( q_n := g_{n-1}^{-1} \sum_{i=1}^j k_i \mu_n(k-e_i) \) for all \( n \geq \max(2, j) \). Thus,

\[
(n-1)(n-1)_{j-1} a_n = (n-1)(n-1)_{j-1} q_n + \sum_{m=j+1}^{n-1} \frac{m-1}{n-m(n-m+1)} a_m.
\]

Before we come back to the recursion (13) let us first verify that

\[
\sum_{n=\max(2,j)}^{\infty} (n-1)(n-1)_{j-1} q_n z^{n-j} = g_k(z), \quad z \in D.
\]

Obviously (14) holds for \( j = 1 \) and \( k_1 = 1 \), since in this case \( q_n = 1/g_n = 1/(n-1) \) and \( g_1(z) = z/(1-z) \) by definition. For \( k = (k_1, \ldots, k_j) \in \mathbb{N}^j \) with \( k_1 + \cdots + k_j > 1 \) we have

\[
\sum_{n=\max(2,j)}^{\infty} (n-1)(n-1)_{j-1} q_n z^{n-j} = \sum_{n=\max(2,j)}^{\infty} (n-1)_{j-1} \sum_{i=1}^{j} k_i \mu_n(k-e_i) z^{n-j}
\]

\[
= \left( \frac{d}{dz} \right)^{j-1} \sum_{i=1}^{j} k_i \sum_{n=\max(2,j)}^{\infty} \mu_n(k-e_i) z^{n-1} = \sum_{i=1}^{j} k_i f_{k-e_i}^{(j-1)}(z) = g_k(z).
\]
Thus, (14) is established. In view of \((n-1)\binom{n-2}{j-1} = (n-1)_{j-1} + (j-1)(n-1)_{j-1} + (14), by multiplying both sides in (13) with \(z^n - j\) and summing over all \(n \geq \max(2,j)\), the recursion (13) translates to

\[
z f_k^{(j)}(z) + (j-1) f_k^{(j-1)}(z) = g_k(z) + \sum_{n = \max(2,j)}^{\infty} \sum_{m = j+1}^{n-1} (m-1)_j \frac{a_m}{n(n+m+1)} z^{n-j}
\]

\[
= g_k(z) + \sum_{m = j+1}^{\infty} (m-1)_j a_m z^{m-j} \sum_{n = m+1}^{\infty} \frac{1}{n(n+m+1)} z^{n-m}
\]

\[
= g_k(z) + za(z) (\frac{d}{dz})^j \sum_{m = j}^{\infty} a_m z^{m-1}
\]

\[
= g_k(z) + za(z) f_k^{(j)}(z), \tag{15}
\]

where \(a(z) := \sum_{n = 1}^{\infty} \frac{z^n}{n(n+1)}\) for \(z \in D\). Since \(z(1-a(z)) = (1-z)L(z)\), the differential equation (15) can be rewritten in the form (10). For \(j > 1\) the only solution of (10) being continuous at 0 (and for \(j = 1\) the only solution of (10) with \(f_2(0) = 0\) is given by (11). Since \(g_1(z) = z/(1-z)\), (11) reduces for \(j := k_1 := 1\) to the first equation in (12), in agreement with (12) Lemma 3.1, Eq. (3.3)]. Noting that \(g_{(1,1)}(z) = f'_{(0,1)}(z) + f'_{(1,0)}(z) = 2f'(z) = 2z/(1-z)^2L(z)\), the formula for \(f'_{(1,1)}(z)\) in (12) follows by choosing \(j := 2\) and \(k_1 := k_2 := 1\) in (11).

**Corollary 3.2** (Exact formula for \(E(\tau_{n,1}, \tau_{n,2})\))

Fix \(n \in \{2,3,\ldots\}\). For the Bolthausen–Sznitman coalescent,

\[
E(\tau_{n,1}, \tau_{n,2}) = \frac{2}{(n-1)!} \sum_{k=1}^{n-1} \frac{2k-1}{k^2} s(n-2,k-1), \tag{16}
\]

where the \(s(n,k)\) denote the absolute Stirling numbers of the first kind.

**Remark.** Together with the exact formula \(E(\tau_{n,1}) = ((n-1)!)^{-1} \sum_{k=1}^{n-1} s(n-1,k)/k\) for the mean of \(\tau_{n,1}\) (see, for example, Proposition 1.2 of [12]) it can be checked that \(\operatorname{Cov}(\tau_{n,1}, \tau_{n,2}) = E(\tau_{n,1}, \tau_{n,2}) - (E(\tau_{n,1}))^2 > 0\) for all \(n \geq 2\). Thus, for all \(n \geq 2\), \(\tau_{n,1}\) and \(\tau_{n,2}\) are positively correlated. We have used the exact formulas for \(E(\tau_{n,1})\) and \(E(\tau_{n,1}, \tau_{n,2})\) to compute the entries of the following table.

Table 2: Covariance of \(\tau_{n,1}\) and \(\tau_{n,2}\) for the Bolthausen–Sznitman coalescent

**Proof.** (of Corollary 3.2) We write \(f := f'_{(1,1)}\) for convenience. The substitution \(u = L(t) = -\log(1-t)\) below the second integral in (12) yields

\[
f'(z) = \frac{2}{L(z)} \int_0^{L(z)} \frac{e^{u} - e^{u}}{u} \, du
\]
In order to verify the induction step from \(d\), it remains to divide by \(i\).

From (see [1] p. 824) \((L(z))^k/k! = \sum_{i=k}^{\infty} z^i/i! s(i,k)\) we conclude that

\[
f'(z) = 2 \sum_{k=1}^{\infty} \frac{2^k - 1}{k^2} \sum_{i=k-1}^{\infty} z^i \frac{s(i, k-1)}{i!} = 2 \sum_{i=0}^{\infty} \frac{z^i}{i!} \sum_{k=1}^{\infty} \frac{2^k - 1}{k^2} s(i, k-1).
\]

For a power series \(g(z) = \sum_{n=0}^{\infty} g_n z^n\) we denote in the following with \([z^n]g(z) := g_n\) the coefficient in front of \(z^n\) in the series expansion of \(g\). Using this notation we obtain

\[(i+1)E(\tau_{i+2,1} \tau_{i+2,2}) = [z^i]f'(z) = 2 \sum_{i=0}^{\infty} \frac{z^i}{i!} \sum_{k=1}^{\infty} \frac{2^k - 1}{k^2} s(i, k-1).
\]

It remains to divide by \(i + 1\) and to substitute \(n = i + 2\).

### 4 Proofs of Theorem 1.2, Corollary 1.3 and Corollary 1.4

**Proof.** (of Theorem 1.2) Let us verify (6) by induction on the degree \(d := k_1 + \cdots + k_j\). Obviously (6) holds for \(d = 0\), i.e. for all \(j \in \mathbb{N}\) and \(k_1 = \cdots = k_j = 0\). In order to verify (6) for \(d = 1\) it suffices to show that \(a_n := \mu_n(1) \sim 1/\log n\) as \(n \to \infty\) since \(\mu_n(k) = \mu_n(1)\) for all \(k = (k_1, \ldots, k_j) \in \mathbb{N}_0^j\) satisfying \(k_1 + \cdots + k_j = 1\). By (12) and de l’Hospital’s rule

\[
f_1(z) = \int_0^z \frac{t}{(1-t)^2 L(t)} \, dt \sim \frac{1}{(1-z)L(z)} \sim 1.
\]

Since \(a_n = E(\tau_{n,1})\) is non-increasing in \(n\), Karamata’s Tauberian theorem for power series [4] p. 40, Corollary 1.7.3, applied with \(c := \rho := 1\) and \(l(x) := 1/\log x\), yields \(a_n \sim l(n) = 1/\log n\). Thus, (6) holds for \(d = 1\).

In order to verify the induction step from \(d - 1\) to \(d > 1\) fix \(k = (k_1, \ldots, k_j) \in \mathbb{N}_0^j\) with \(d = k_1 + \cdots + k_j > 1\). We can and do assume without loss of generality that \(k = (k_1, \ldots, k_j) \in \mathbb{N}^j\). By the induction hypothesis

\[
b_n := \sum_{i=1}^{j} k_i \mu_n(k - e_i) \sim \sum_{i=1}^{j} \frac{k_1! \cdots (k_i - 1)! \cdots k_j!}{\log^{d-1} n} \sim \frac{j k_1! \cdots k_j!}{\log^{d-1} n}, n \to \infty.
\]
Since $b_n$ is non-increasing in $n$, the same Tauberian theorem as used above for $d = 1$, but now applied with $c := jk_1! \cdots k_j!$, $\rho := 1$ and $l(x) := 1/\log ^{d-1} x$, yields

$$b(z) := \sum_{n=\max(2,j)}^\infty b_n z^{n-1} \sim \frac{jk_1! \cdots k_j!}{(1-z)(L(z))^{d-1}}, \quad z \nearrow 1.$$ 

Note that $b(z) = \sum_{j=1}^j k_1 f_{k_1-e}(z)$. Applying de l’Hospital’s rule $(j-1)$-times yields

$$g_k(z) = \sum_{i=1}^j k_i f_{k_i-e_i}(z) = b^{(j-1)}(z) \sim \frac{j! k_1! \cdots k_j!}{(1-z)^j (L(z))^{d-1}}, \quad z \nearrow 1.$$ 

Thus, by (11) and by one further application of de l’Hospital’s rule,

$$f_k^{(j-1)}(z) = \frac{1}{(L(z))^{j-1}} \int_0^z \frac{(L(t))^{j-2}}{1-t} g_k(t) \, dt \sim \frac{(j-1)! k_1! \cdots k_j!}{(1-z)^j (L(z))^{d-1}}, \quad z \nearrow 1.$$ 

Using again de l’Hospital’s rule $(j-1)$-times it follows that

$$f_k(z) \sim \frac{k_1! \cdots k_j!}{(1-z)(L(z))^{d}}, \quad z \nearrow 1.$$ 

Since $a_n := \mu_n(k)$ is non-increasing in $n$, again Karamata’s Tauberian theorem for power series, now applied with $c := k_1! \cdots k_j!$, $\rho := 1$ and $l(x) := 1/\log ^d x$, yields $a_n \sim k_1! \cdots k_j! / \log ^d n$. \hfill \Box

**Proof.** (of Corollary 1.3) Theorem 1.2 clearly implies that, for $j \in \mathbb{N}$ and $k_1, \ldots, k_j \in \mathbb{N}$, $\mathbb{E}((\tau_{n,1} \log n)^{k_1} \cdots (\tau_{n,j} \log n)^{k_j}) = (\log n)^{k_1+\cdots+k_j} \mu_n(k_1,\ldots,k_j) \to k_1! \cdots k_j! = \mathbb{E}(\tau_1^{k_1} \cdots \tau_j^{k_j})$ as $n \to \infty$. For all $i \in \{1, \ldots, j\}$ and all $0 \leq \theta < 1$ we have $\sum_{r=0}^\infty (\theta^r / r!) \mathbb{E}(\tau_i^r) = \sum_{r=0}^\infty \theta^r = 1/(1-\theta) < \infty$. Therefore (see [2]. Theorems 30.1 and 30.2 for the one-dimensional case and Problem 30.6 on p. 398 for the multi-dimensional case) the above convergence of moments implies the convergence $(\log n)(\tau_{n,1}, \ldots, \tau_{n,j}) \to (\tau_1, \ldots, \tau_j)$ in distribution as $n \to \infty$ for each $j \in \mathbb{N}$. The convergence of all these $j$-dimensional distributions is already equivalent (see Billingsley [3, p. 19]) to the convergence of the full processes $(\log n)(\tau_{n,1}, \ldots, \tau_{n,n}, 0, 0, \ldots) \to (\tau_1, \tau_2, \ldots)$ in distribution as $n \to \infty$. \hfill \Box

**Proof.** (of Corollary 1.4) The external branch length $L_n^{external}$ satisfies (see [22, p. 2165])

$$\mathbb{E}((L_n^{external})^k) = \sum_{j=1}^k \binom{n}{j} \sum_{k_1, \ldots, k_j \in \mathbb{N}, k_1 + \cdots + k_j = k} \frac{k!}{k_1! \cdots k_j!} \mu_n(k_1, \ldots, k_j), \quad n \in \{2, 3, \ldots\}, k \in \mathbb{N}.$$ 

By Theorem 1.2 $\mu_n(k_1, \ldots, k_j) \sim k_1! \cdots k_j! / \log ^k n$ as $n \to \infty$. Therefore, asymptotically the summand with index $j = k$ dominates the others, so asymptotically all the summands with indices $j < k$ can be disregarded. Thus, $\mathbb{E}((L_n^{external})^k) \sim \binom{n}{k} k! / \log ^k n \sim n^k / \log ^k n$. This convergence of all moments $\mathbb{E}((L_n^{external})^k) \to 1$ as $n \to \infty$ implies the convergence $\log _n L_n^{external} \to 1$ in distribution (and hence in probability) as $n \to \infty$. \hfill \Box
