Abstract

Regularization plays a pivotal role when facing the challenge of solving ill-posed inverse problems, where the number of observations is smaller than the ambient dimension of the object to be estimated. A line of recent work has studied regularization models with various types of low-dimensional structures. In such settings, the general approach is to solve a regularized optimization problem, which combines a data fidelity term and some regularization penalty that promotes the assumed low-dimensional/simple structure. This paper provides a general framework to capture this low-dimensional structure through what we coin piecewise regular gauges. These are convex, non-negative, closed, bounded and positively homogenous functions that will promote objects living on low-dimensional subspaces. This class of regularizers encompasses many popular examples such as the $\ell^1$ norm, $\ell^1 - \ell^2$ norm (group sparsity), nuclear norm, as well as several others including the $\ell^\infty$ norm. We will show that the set of piecewise regular gauges is closed under addition and pre-composition by a linear operator, which allows to cover mixed regularization (e.g. sparse+low-rank), and the so-called analysis-type priors (e.g. total variation, fused Lasso, trace Lasso, bounded polyhedral gauges). Our main result presents a unified sharp analysis of exact and robust recovery of the low-dimensional subspace model associated to the object to recover from partial measurements. This analysis is illustrated on a number of special and previously studied cases.

Keywords: Convex regularization, Inverse problems, Piecewise regular gauge, Model selection, Sparsity, Noise robustness.
1. Introduction

1.1. Regularization of Linear Inverse Problems

Inverse problems are encountered in various areas throughout science and engineering. The goal is to provably recover the structure underlying an object \( x_0 \in \mathbb{R}^N \), either exactly or to a good approximation, from the partial measurements

\[
y = \Phi x_0 + w,
\]

where \( y \in \mathbb{R}^Q \) is the vector of observations, \( w \in \mathbb{R}^Q \) stands for the noise, and \( \Phi \in \mathbb{R}^{Q \times N} \) is a linear operator which maps the \( N \)-dimensional signal domain onto the \( Q \)-dimensional observation domain. The operator \( \Phi \) is in general ill-conditioned or singular, so that solving for an accurate approximation of \( x_0 \) from (1) is ill-posed.

The situation however changes if one imposes some prior knowledge on the underlying object \( x_0 \), which makes the search for solutions to (1) feasible. This can be achieved via regularization which plays a fundamental role in bringing back ill-posed inverse problems to the land of well-posedness. We here consider solutions to the regularized optimization problem

\[
\min_{x \in \mathbb{R}^N} \frac{1}{2} ||y - \Phi x||^2 + \lambda J(x),
\]

where the first term translates the fidelity of the forward model to the observations, and \( J \) is the regularization term intended to promote solutions conforming to some notion of simplicity/low-dimensional structure, that is made precise later. The regularization parameter \( \lambda > 0 \) is adapted to balance between the allowed fraction of noise level and regularity as dictated by the prior on \( x_0 \). Before proceeding with the rest, it is worth mentioning that although we focus our analysis on the penalized form (\( P_\lambda(y) \)), our results can be extended with minor adaptations to the constrained formulation, i.e. the one where the data fidelity is put as a constraint. Note also that we focus our attention for simplicity to an \( \ell^2 \) fidelity, although our analysis carries over to more general smooth and strongly convex fidelity terms.

When there is no noise in the observations, i.e. \( w = 0 \) in (1), the equality-constrained minimization problem should be solved

\[
x^* \in \arg\min_{x \in \mathbb{R}^N} J(x) \quad \text{subject to} \quad \Phi x = y. \quad (P_0(y))
\]

1.2. Gauges and Model Selection

In this paper, we consider the general case where \( J \) is a gauge associated to a convex set \( C \) containing the origin as an interior point, or equivalently, that \( J \) is a gauge whose domain is full. In plain words, \( J \) is a convex, non-negative, continuous (hence bounded) and positively homogeneous function (see Section 2.1 for details).

This class of regularizers \( J \) include many well-studied ones in the literature. Among them, one can think of the \( \ell^1 \) norm used to enforce sparse solutions [38], the discrete
total variation semi-norm \cite{35}, the $\ell^1 - \ell^2$ norm to induce block/group sparsity \cite{44}, the nuclear norm for low-rank matrices \cite{16,8}, or bounded polyhedral gauges \cite{41}.

The behavior of this class of regularizers is dictated by the geometry of $C$, which is nothing in this case but the sublevel set at 1 of $J$, i.e., $C = \{ x \in \mathbb{R}^N : J(x) \leq 1 \}$, see Lemma 1. In particular, each point at which $C$ is non-smooth encodes some low-dimensional subspace model. The regularization $J$ then promotes solutions living in one of these subspaces. A typical example is that of the $\ell^1$-norm where the promoted vectors are sparse, living on low-dimensional subspaces aligned with the axes.

Assuming that the gauges enjoy some piecewise regularity properties, our goal in this paper is to provide a unified analysis of exact and robust recovery guarantees of the subspace model underlying the object $x_0$ by solving ($P_\lambda(y)$) from the partial measurements in ($P_\lambda(y)$). As a by-product, this entails a control on the $|x^* - x_0|$, where $x^*$ is the unique minimizer of ($P_\lambda(y)$).

1.3. Contributions

Our main contributions are as follows.

1.3.1. Subdifferential Decomposability of Gauges

Building upon Definition 5, which introduces the model subspace $T_x$ at $x$, we provide an equivalent description of the subdifferential of a bounded gauge at $x$ in Theorem 1. Such a description isolates and highlights a key property of a regularizing gauge, namely decomposability. In turn, this property allows to rewrite the first-order minimality conditions of ($P_\lambda(y)$) and ($P_0(y)$) in a convenient and compact way, and this lays the foundations of our subsequent contributions.

1.3.2. Uniqueness

In Theorem 2, we state a sharp sufficient condition, dubbed the Strong Null Space Property, to ensure that the solution of ($P_\lambda(y)$) or ($P_0(y)$) is unique. In Corollary 1, we provide a weaker sufficient condition, stated in terms of a dual vector, the existence of which certifies uniqueness. Putting together Theorem 1 and Corollary 1, Theorem 3 states the sufficient uniqueness condition in terms of a specific dual certificate built from ($P_\lambda(y)$) and ($P_0(y)$).

1.3.3. Piecewise Regular Gauges

In the quest for establishing robust recovery of the subspace model $T_{x_0}$, we first need to quantify the stability of the subdifferential of the regularizer $J$ to local perturbations of its argument. Thus, to handle such a change of geometry, we introduce the notion of piecewise regular gauge (see Definition 9).

We show in particular that two important operations preserve piecewise regularity. In Proposition 8 and Proposition 10, we show that piecewise regularity of gauges is preserved under addition and pre-composition by a linear operator. Consequently, more
intricate regularizers can be built starting from simple gauges, e.g. $\ell^1$-norm, nuclear norm, etc., which are known to be piecewise regular (see the review given in Section 6).

### 1.3.4. Exact and Robust Subspace Recovery

This is the core contribution of the paper. Assuming the gauge is piecewise regular, we show in Theorem 5 that under a generalization of the irrepresentable condition [17], and with the proviso that the noise level is bounded and the minimal signal-to-noise ratio is high enough, there exists a whole range of the parameter $\lambda$ for which problem $(P_\lambda(y))$ has a unique solution $x^*$ living in the same subspace as $x_0$. In turn, this yields a control on $\ell^2$-recovery error within a factor of the noise level, i.e. $||x^* - x_0|| = O(||w||)$. In the noiseless case, the irrepresentable condition implies that $x_0$ is exactly identified by solving $(P_0(y))$.

### 1.4. Related Work

In [7], the authors introduced the notion of decomposable norms. In fact, we show that their regularizers are a very special subclass of ours that corresponds to strong decomposability in the sense of the Definition 8, beside symmetry since norms are symmetric gauges. Moreover, their definition involves two conditions, the second of which turns out to be an intrinsic property of gauges rather than an assumption; see the discussion after Proposition 6. Typical examples of (strongly) decomposable norms are the $\ell^1$, $\ell^1 - \ell^2$ and nuclear norms. However, strong decomposability excludes many important cases. One can think of analysis-type semi-norms since strong decomposability is not preserved under pre-composition by a linear operator, or the $\ell^\infty$ norm among many others. The analysis provided in [7] deals only with identifiability in the noiseless case. Their work was extended in [29] when $J$ is the sum of decomposable norms.

Arguments based on Gaussian width were used in [9] to provide sharp estimates of the number of generic measurements required for exact and $\ell^2$-stable recovery of atomic set models from random partial information by solving a constrained form of $(P_\lambda(y))$ regularized by an atomic norm. The atomic norm framework was then exploited in [31] in the particular case of the group Lasso and union of subspace models. This is however restricted to the compressed sensing scenario.

A notion of decomposability closely related to that of [7], but different, was proposed in [27]. There, the authors study $\ell^2$-stability for this class of decomposable norms with a general sufficiently smooth data fidelity. This work however only handles norms, and their stability results require however stronger assumptions than ours (typically a restricted strong convexity which becomes a type of restricted eigenvalue property for linear regression with quadratic data fidelity).

In the inverse problems literature, a convergence (stability) rates have been derived in [5] with respect to the Bregman divergence for general convex regularizations $J$. The author in [18] established a stability result for general sublinear functions $J$. The stability is however measured in terms of $J$, and $\ell^2$-stability can only be obtained if $J$ is coercive, which, again, excludes a large class of gauges. In [15], a $\ell^2$-stability result for decomposable norms (in the sense of [7]) precomposed by a linear operator is proved.
However, none of these works deals with exact and robust recovery of the subspace model underlying $x_0$.

1.5. Paper Organization

The outline of the paper is the following. Section 2 gives essential properties of gauges and their polars, and then fully characterizes the canonical decomposition of the subdifferential of a gauge with respect to the subspace model at $x$. Sufficient conditions ensuring uniqueness of the minimizers to $(P_\lambda(y))$ and $(P_0(y))$ are provided in Section 3. In Section 4, we introduce the notion of a piecewise regular gauge and show that this property is preserved under addition and pre-composition by a linear operator. Section 5 is dedicated to our main result, namely theoretical guarantees for exact subspace recovery in presence of noise, and identifiability in the noiseless case. Section 6 exemplifies our results on several previously studied priors, and a detailed discussion on the relation with respect to relevant previous work is provided. Some conclusions and possible perspectives of this work are drawn in Section 7. The proofs of our results are collected in the appendix.

1.6. Notations and Elements from Convex Analysis

In the following, if $\mathcal{T}$ is a vector space, $P_\mathcal{T}$ denotes the orthogonal projector on $\mathcal{T}$, and $x_\mathcal{T} = P_\mathcal{T}(x)$ and $\Phi_\mathcal{T} = \Phi P_\mathcal{T}$.

For a subset $I$ of $\{1, \ldots, N\}$, we denote by $I^c$ its complement, $|I|$ its cardinality. $x_{(I)}$ is the subvector whose entries are those of $x$ restricted to the indices in $I$, and $\Phi_{(I)}$ the submatrix whose columns are those of $\Phi$ indexed by $I$. For any matrix $A$, $A^*$ denotes its adjoint matrix and $A^+$ its Moore–Penrose pseudo-inverse. We denote the right-completion of the real line by $\overline{\mathbb{R}} = \mathbb{R} \cup \{+\infty\}$.

A real-valued function $f : \mathbb{R}^N \to \mathbb{R}$ is coercive, if $\lim \|x\| \to +\infty f(x) = +\infty$. The effective domain of $f$ is defined by $\text{dom } f = \{x \in \mathbb{R}^N : f(x) < +\infty \}$ and $f$ is proper if $\text{dom } f \neq \emptyset$. We say that a real-valued function $f$ is lower semi-continuous (lsc) if $\liminf_{z \to x} f(z) \geq f(x)$. A function is said sublinear if it is convex and positively homogeneous.

Let the kernel of a function be denoted $\text{Ker } f = \{x \in \mathbb{R}^N : f(x) = 0\}$. $\text{Ker } f$ is a convex cone when $f$ is positively homogeneous.

We now provide some elements from convex analysis that are necessary throughout this paper. A comprehensive account can be found in [33, 20].

Sets For a non-empty set $C \subset \mathbb{R}^N$, we denote $\overline{\text{co }}(C)$ the closure of its convex hull. Its affine hull $\text{aff } C$ is the smallest affine manifold containing it, i.e.

$$\text{aff } C = \left\{ \sum_{i=1}^{k} \rho_i x_i : k > 0, \rho_i \in \mathbb{R}, x_i \in C, \sum_{i=1}^{k} \rho_i = 1 \right\}.$$

It is included in the linear hull $\text{span } C$ which is the smallest subspace containing $C$. 

5
The interior of $C$ is denoted $\text{int} C$. The relative interior $\text{ri} C$ of a convex set $C$ is the interior of $C$ for the topology relative to its affine hull.

**Functions** Let $C$ a nonempty convex subset of $\mathbb{R}^N$. The indicator function $\iota_C$ of $C$ is

$$\iota_C(x) = \begin{cases} 0, & \text{if } x \in C, \\ +\infty, & \text{otherwise}. \end{cases}$$

The Legendre-Fenchel conjugate of a proper, lsc and convex function $f$ is

$$f^*(u) = \sup_{x \in \text{dom } f} \langle u, x \rangle - f(x),$$

where $f^*$ is proper, lsc and convex, and $f^{**} = f$. For instance, the conjugate of the indicator function $\iota_C$ is the support function of $C$

$$\sigma_C(u) = \sup_{x \in C} \langle u, x \rangle.$$

$\sigma_C$ is sublinear, is non-negative if $0 \in C$, and is finite everywhere if, and only if, $C$ is a bounded set.

Let $f$ and $g$ be two functions proper closed convex functions from $\mathbb{R}^N$ to $\mathbb{R}$. Their infimal convolution is the function

$$(f \vee g)(x) = \inf_{x_1 + x_2 = x} f(x_1) + g(x_2) = \inf_{x \in \mathbb{R}^N} f(z) + g(x - z).$$

The subdifferential $\partial f(x)$ of a convex function $f$ at $x$ is the set

$$\partial f(x) = \left\{ u \in \mathbb{R}^N : f(x') \geq f(x) + \langle u, x' - x \rangle, \quad \forall x' \in \text{dom } f \right\}.$$

An element of $\partial f(x)$ is a subgradient. If the convex function $f$ is Gâteaux-differentiable at $x$, then its only subgradient is its gradient, i.e. $\partial f(x) = \{ \nabla f(x) \}$.

The directional derivative $f'(x, \delta)$ of a lsc function $f$ at the point $x \in \text{dom } f$ in the direction $\delta \in \mathbb{R}^N$ is

$$f'(x, \delta) = \lim_{t \downarrow 0} \frac{f(x + t\delta) - f(x)}{t}.$$

When $f$ is convex, then the function $\delta \mapsto f'(x, \cdot)$ exists and is sublinear. The subdifferential $\partial f(x)$ is a non-empty compact convex set of $\mathbb{R}^N$ whose support function is $f'(x, \cdot)$, i.e.

$$f'(x, \delta) = \sigma_{\partial f(x)}(\delta) = \sup_{\eta \in \partial f(x)} \langle \eta, \delta \rangle.$$

We also recall the fundamental first-order minimality condition of a convex function: $x^*$ is the global minimizer of a convex function $f$ if, and only if, $0 \in \partial f(x)$.
2. Geometry of Gauge Regularization

2.1. Gauges and their Polars

Definitions and main properties. We start by collecting some important properties of gauges and their polars. A comprehensive account on them can be found in [33].

We begin with the definition of a gauge.

**Definition 1 (Gauge).** Let \( C \subseteq \mathbb{R}^N \) be a non-empty closed convex set containing the origin. The gauge of \( C \) is the function \( \gamma_C \) defined on \( \mathbb{R}^N \) by

\[
\gamma_C(x) = \inf \{ \lambda > 0 : x \in \lambda C \}.
\]

As usual, \( \gamma_C(x) = +\infty \) if the infimum is not attained.

**Lemma 1.**

(i) \( \gamma_C \) is a non-negative, lsc and sublinear function.

(ii) \( C \) is the unique closed convex set containing the origin such that

\[
C = \{ x \in \mathbb{R}^N : \gamma_C(x) \leq 1 \}.
\]

(iii) \( \gamma_C \) is bounded if, and only if, \( 0 \in \text{int} C \), in which case \( \gamma_C \) is continuous.

(iv) \( \text{Ker} \gamma_C = \{0\} \), or equivalently \( \gamma_C \) is coercive if, and only if, \( C \) is compact.

(v) \( \gamma_C \) is bounded and coercive on \( \text{dom} \gamma_C = \text{span} C \) if, and only if, \( C \) is compact and \( 0 \in \text{ri} C \). In particular, \( \gamma_C \) is bounded and coercive if, and only if, \( C \) is compact and \( 0 \in \text{int} C \).

Lemma 1(ii) is fundamental result of convex analysis that states that there is a one-to-one correspondence between gauge functions and closed convex sets containing the origin. This allows to identify sets from their gauges, and vice versa. Recall that in this paper, we consider a regularizing gauge \( J \) associated to a convex set \( C \) containing the origin as an interior point, or equivalently by Lemma 1(i)-(iii), that \( J \) is a non-negative, continuous and sublinear function of full domain.

\( \gamma_C \) is a norm, having \( C \) as its unit ball, if and only if \( C \) is bounded with nonempty interior and symmetric. When \( C \) is only symmetric with nonempty interior, then \( \gamma_C \) becomes a semi-norm.

Let us now turn to the polar of a convex set and a gauge.

**Definition 2 (Polar set).** Let \( C \) be a non-empty convex set. The set \( C^o \) given by

\[
C^o = \{ v \in \mathbb{R}^N : (v, x) \leq 1 \text{ for all } x \in C \}
\]

is called the polar of \( C \).
$C^\circ$ is a closed convex set containing the origin. When the set $C$ is also closed and contains the origin, then it coincides with its bipolar, i.e. $C^{\circ\circ} = C$.

We are now in position to define the polar gauge.

**Definition 3 (Polar Gauge).** The polar of a gauge $\gamma_C$ is the function $\gamma_C^\circ$ defined by

$$
\gamma_C^\circ(u) = \inf \{ \mu \geq 0 : \langle x, u \rangle \leq \mu \gamma_C^\circ(x), \forall x \} .
$$

Observe that gauges polar to each other have the property

$$
\langle x, u \rangle \leq \gamma_C^\circ(x) \gamma_C^\circ(u), \forall (x, u) \in \text{dom } \gamma_C \times \text{dom } \gamma_C^\circ ,
$$

just as dual norms satisfy a duality inequality. In fact, polar pairs of gauges correspond to the best inequalities of this type.

**Lemma 2.** Let $C \subseteq \mathbb{R}^N$ be a closed convex set containing $0$. Then,

(i) $\gamma_C^\circ$ is a gauge function and $\gamma_C^{\circ\circ} = \gamma_C$.

(ii) $\gamma_C^\circ = \gamma_{C^\circ}$, or equivalently

$$
C^\circ = \{ x \in \mathbb{R}^N : \gamma_C^\circ(x) \leq 1 \} = \{ x \in \mathbb{R}^N : \gamma_{C^\circ}(x) \leq 1 \} .
$$

(iii) The gauge of $C$ and the support function of $C$ are mutually polar, i.e.

$$
\gamma_C = \sigma_{C^\circ} \quad \text{and} \quad \gamma_{C^\circ} = \sigma_C .
$$

**Gauge and polar calculus** We here derive the expression of the gauge function of the Minkowski sum of two sets, as well as that of the image of a set by a linear operator. These results play an important role in Section 4.

**Lemma 3.** Let $C_1$ and $C_2$ be nonempty closed convex sets containing the origin. Then

$$
\gamma_{C_1 + C_2}(x) = \sup_{\rho \in [0,1]} \rho \gamma_{C_1}^\circ + (1 - \rho) \gamma_{C_2}^\circ(x) .
$$

If $x$ is such that $\gamma_{C_1}(x_1) + \gamma_{C_2}(x_2)$ is continuous and bounded on $\{(x_1, x_2) : x_1 + x_2 = x\}$, then

$$
\gamma_{C_1 + C_2}(x) = \inf_{z \in \mathbb{R}^N} \max(\gamma_{C_1}(z), \gamma_{C_2}(x - z)) .
$$

**Lemma 4.** Let $C$ be a closed convex set such that $0 \in \text{ri } C$, and $D$ a linear operator. Then, for every $x \in \text{Im}(D)$

$$
\gamma_{D(C)}(x) = \inf_{z \in \text{Ker}(D)} \gamma_C(D^+ x + z) .
$$

Using Lemma 1(v), one can observe that the infimum is bounded if $(D^+ x + \text{Ker}(D)) \cap \text{span } C \neq \emptyset$.
Operator bound

**Definition 4.** Let $J_1$ and $J_2$ be two gauges defined on two vector spaces $V_1$ and $V_2$, and $A: V_1 \to V_2$ a linear map. The operator bound $M_{J_1,J_2}(A)$ of $A$ between $J_1$ and $J_2$ is given by

$$M_{J_1,J_2}(A) = \sup_{J_1(x) \leq 1} J_2(Ax).$$

Note that $M_{J_1,J_2}(A) < +\infty$ if, and only if $A \text{Ker}(J_1) \subseteq \text{Ker}(J_2)$. In particular, if $J_1$ is coercive (i.e. $\text{Ker} J_1 = \{0\}$ from Lemma 1(iv)), then $M_{J_1,J_2}(A)$ is finite. As a convention, $M_{J_1,||\cdot||_p}(A)$ is denoted as $M_{J_1,\ell_p}(A)$. An easy consequence of this definition is the fact that for every $x \in V_1$,

$$J_2(Ax) \leq M_{J_1,J_2}(A)J_1(x).$$

We end this section by pointing out that many of the results proved in this paper can be extended to $f$-homogenous closed convex functions $J$, i.e. $J(\lambda x) = f(\lambda)J(x)$, $\forall x$ and $\lambda > 0$ for a positive continuous increasing convex function $f$ on $\mathbb{R}_+$. These are gauge-like functions that can be built from gauges as $J = g \circ \gamma_C$, where $g$ is a non-constant non-decreasing and lsc convex function on $\mathbb{R}_+$ such that $g(\lambda t) = f(\lambda)g(t)$. This construction can be proved from [33, Theorem 15.3]. An important class is that of positively homogenous functions of degree $p$, in which case $g(t) = t^p/p$ and $f(\lambda) = \lambda^p$ for $1 \leq p < \infty$. One can show that the main robust recovery result proved in this paper can be extended to $f$-homogenous closed convex functions, at the price of modifying the scaling between the regularization parameter $\lambda$ and the noise level.

2.2. Model Subspace Associated to a Gauge

Let $J$ our regularizer, i.e. a bounded gauge. We now introduce the model subspace at a point $x$.

**Definition 5 (Model Subspace).** For any vector $x \in \mathbb{R}^N$, we denote by $\tilde{S}_x$ the affine hull of the subdifferential of $J$ at $x$

$$\tilde{S}_x = \text{aff} \partial J(x),$$

and $e_x$ the orthogonal projection of $0$ onto $\tilde{S}_x$

$$e_x = \text{argmin}_{e \in \tilde{S}_x} |e|.$$

We denote

$$S_x = \tilde{S}_x - e_x = \text{span}(\partial J(x) - e_x) \quad \text{and} \quad T_x = S_x^\perp.$$

$T_x$ is coined the model subspace of $x$ associated to $J$. 

When \( J \) is Gateaux-differentiable at \( x \), i.e. \( \partial J(x) = \{ \nabla J(x) \} \), \( e_x = \nabla J(x) \) and \( T_x = \mathbb{R}^N \). On the contrary, when \( J \) is not smooth at \( x \), the dimension of \( T_x \) is smaller dimension, and the regularizing gauge \( J \) essentially promotes elements living on this model subspace.

We start by summarizing some key properties of the objects \( e_x \) and \( T_x \).

**Proposition 1.** For any \( x \in \mathbb{R}^N \), one has

(i) For every \( u \in \bar{S}_x \), \( J(x) = \langle u, x \rangle \).

(ii) \( e_x \in T_x \cap \bar{S}_x \).

(iii) \( \bar{S}_x = \{ \eta \in \mathbb{R}^N : \eta T_x = e_x \} \).

(iv) \( x \in T_x \).

In general \( e_x \notin \partial J(x) \), which is the situation displayed on Figure 1. It is worth noting that the fact that \( e_x \in T_x \cap \bar{S}_x \) holds for any proper convex function, not only gauges, whereas \( x \in T_x \) does not hold in general.

![Figure 1: Illustration of the geometrical elements (\( S_x, T_x, e_x \)).](image)

From this section until Section 4, we use the \( \ell^1-\ell^2 \) and the \( \ell^\infty \) norms as illustrative examples. A more comprehensive treatment is provided in Section 6 completely dedicated to examples.

**Examples**

*Example 1 (\( \ell^1-\ell^2 \) norm).* We consider a uniform disjoint partition \( B \) of \( \{1, \cdots, N\} \),

\[
\{1, \ldots, N\} = \bigcup_{b \in B} b, \quad b \cap b' = \emptyset, \quad \forall b \neq b'.
\]

The \( \ell^1 - \ell^2 \) norm of \( x \) is

\[
J(x) = \|x\|_B = \sum_{b \in B} |x_b|.
\]
The subdifferential of $J$ at $x \in \mathbb{R}^N$ is

$$\partial J(x) = \left\{ \eta \in \mathbb{R}^N : \forall b \in I, \eta_b = \frac{x_b}{|x_b|} \quad \text{and} \quad \forall g \notin I, \|\eta_g\| \leq 1 \right\},$$

where $I = \{ b \in B : x_b \neq 0 \}$. Thus, the affine hull of $\partial J(x)$ reads

$$\bar{S}_x = \left\{ \eta \in \mathbb{R}^N : \forall b \in I, \eta_b = \frac{x_b}{|x_b|} \right\}.$$

Hence the projection of 0 onto $\bar{S}_x$ is

$$e_x = (\mathcal{N}(x_b))_{b \in B}$$

where $\mathcal{N}(a) = a/|a|$ if $a \neq 0$, and $\mathcal{N}(0) = 0$ and

$$S_x = \bar{S}_x - e_x = \left\{ \eta \in \mathbb{R}^N : \forall b \in I, \eta_b = 0 \right\}.$$

and

$$T_x = S_x^\perp = \left\{ \eta \in \mathbb{R}^N : \forall b \notin I, \eta_b = 0 \right\}.$$

**Example 2** ($\ell^\infty$ norm). The $\ell^\infty$ norm is $J(x) = |x|_\infty = \max_{1 \leq i \leq N} |x_i|$. For $x = 0$, $\partial J(x)$ is the unit $\ell^1$ ball, hence $\bar{S}_x = S_x = \mathbb{R}^N$. $T_x = \{0\}$ and $e_x = 0$. For $x \neq 0$, we have

$$\partial J(x) = \left\{ \eta : \forall i \in I^c, \eta_i = 0, \langle \eta, s \rangle = 1, \eta_i s_i > 0 \right\}.$$

where $I = \{ i \in \{1, \ldots, N\} : |x_i| = |x|_\infty \}$ and $s = \text{sign}(x)$, with $\text{sign}(0) = 0$. It is clear that $\bar{S}_x$ is the affine hull of an $|I|$-dimensional face of the unit $\ell^1$ ball exposed by the sign subvector $s_{(I)}$. Thus $e_x$ is the barycenter of that face, i.e.

$$e_x = s/|I| \quad \text{and} \quad S_x = \left\{ \eta : \eta_{(I^c)} = 0 \quad \text{and} \quad \langle \eta_{(I)}, s_{(I)} \rangle = 0 \right\}.$$

In turn

$$T_x = S_x^\perp = \left\{ \alpha : \alpha_{(I)} = \rho s_{(I)} \quad \text{for} \quad \rho \in \mathbb{R} \right\}.$$

### 2.3. Decomposability Property

The subdifferential of a gauge $\gamma_C$ at a point $x$ is completely characterized by the face of its polar set $C^\circ$ exposed by $x$. Put formally, we have [20]

$$\partial \gamma_C(x) = F_{C^\circ}(x) = \left\{ \eta \in \mathbb{R}^N : \eta \in C^\circ \quad \text{and} \quad \langle \eta, x \rangle = \gamma_C(x) \right\},$$

where $F_{C^\circ}(x)$ is the face of $C^\circ$ exposed by $x$. The latter is the intersection of $C^\circ$ and the supporting hyperplane $\{ \eta \in \mathbb{R}^N : \langle \eta, x \rangle = \gamma_C(x) \}$. The special case of $x = 0$ has a much simpler structure; it is the polar set $C^\circ$ from Lemma 2(ii)-(iii), i.e.

$$\partial \gamma_C(x) = \left\{ \eta \in \mathbb{R}^N : \gamma_{C^\circ}(\eta) \leq 1 \right\} = C^\circ.$$

The following proposition gives an equivalent convenient description of the subdifferential of the regularizer $J = \gamma_C$ at $x$ in terms of a particular supporting hyperplane to $C^\circ$: the affine hull $\bar{S}_x$. 

11
Proposition 2. Let \( J = \gamma_C \) be a bounded gauge. Then for \( x \in \mathbb{R}^N \), one has 
\[
\partial J(x) = \bar{S}_x \cap C^o.
\]

The antipromoting gauge and its polar Before providing an equivalent description of the subdifferential of \( J \) at \( x \) in terms of the geometrical objects \( e_x, T_x \) and \( S_x \), we introduce another gauge that plays a prominent role in this description.

Definition 6 (Antipromoting Gauge). Let \( J \) be a bounded gauge, and denote \( C \) the associated closed convex set (hence containing the origin in its interior). Let \( x \in \mathbb{R}^N \setminus \{0\} \) and \( f_x \in \text{ri} \partial J(x) \). The antipromoting gauge associated to \( f_x \) is the gauge 
\[
J_{f_x} = \gamma_{\partial J(x) - f_x}.
\]

Since \( \partial J(x) - f_x \) is a closed (in fact compact) convex set containing the origin, it is uniquely characterized by the antipromoting gauge \( J_{f_x} \) (see Lemma 1(i)).

The following proposition states the main properties of the gauge \( J_{f_x} \).

Proposition 3. The antipromoting gauge \( J_{f_x} \) is such that 
\[
\text{dom } J_{f_x} = S_x, \quad \text{and is coercive on } S_x.
\]
Moreover, 
\[
J_{f_x}(\eta) = \inf_{\tau \geq 0} \max_{\eta \in S_x} (J(\tau f_x + \eta), \tau) + \iota_{S_x}(\eta).
\]

The second claim gives a formula which links \( J_{f_x}^\circ \) to the polar gauge \( J^\circ \). But they are not equal in general unless some additional assumptions are imposed on \( J \), as we will see shortly in Section 2.4.

We now turn to the gauge polar to the anti-promoting gauge \( J_{f_x}^\circ = J_{f_x} \), where the last equality is a consequence of Lemma 2(i). \( J_{f_x} \) comes into play in several results in the rest of the paper. The following proposition summarizes its most important properties.

Proposition 4. The gauge \( J_{f_x} \) is such that 
(i) Its has a full domain.
(ii) \( J_{f_x}(d) = J_{f_x}(d_S) = \sup_{\eta \in S_x, \eta_S \leq 1} \iota_{S_x}(\eta, d) \).
(iii) \( \text{Ker } J_{f_x} = T_x \) and \( J_{f_x} \) is coercive on \( S_x \).
(iv) \( J_{f_x}(d) = J(d_S) - \langle f_x, d_S \rangle \).

Let’s derive the antipromoting gauge on the illustrative example of the \( \ell^\infty \) norm.

Example 3 (\( \ell^\infty \) norm). Recall from Section 2.2 that for \( J = | \cdot |_\infty \), \( f_x = e_x = s/|I| \), with \( s = \text{sign}(x) \). Let \( K_x = \partial J(x) - e_x \). It can be straightforwardly shown that in this case, 
\[
K_x = \{ v : \forall (i, j) \in I \times I^c, v_j = 0, \langle v_{(I)}, s_{(I)} \rangle = 0, -|I| v_i s_i \leq 1 \}
\]
This is rewritten as
\[ K_x = S_x \cap \{ v : \forall i \in I, -|I|v_i s_i \leq 1 \} \cdot \]

Thus the antipromoting gauge reads
\[ J^o_{f,x}(\eta) = \gamma_{K_x}(\eta) = \max(\gamma_{S_x}(\eta), \gamma_{K'_x}(\eta)) \cdot \]

We have \( \gamma_{S_x}(\eta) = \iota_{S_x}(\eta) \) and \( \gamma_{K'_x}(\eta) = \max \left( \frac{|I|}{I} s_i \eta_i \right)_+ \), where \((\cdot)_+\) is the positive part, hence we obtain
\[ J^o_{f,x}(\eta) = \begin{cases} \max \left( \frac{|I|}{I} s_i \eta_i \right)_+ & \text{if } \eta \in S_x \\ +\infty & \text{otherwise} \end{cases} \cdot \]

Therefore the subdifferential of \( \| \cdot \|_\infty \) at \( x \) takes the form
\[ \partial J(x) = \left\{ \eta \in \mathbb{R}^N : \eta_T = e_x \quad \text{and} \quad \max \left( \frac{|I|}{I} s_i \eta_i \right)_+ \leq 1 \right\} \cdot \]

**Decomposability of the subdifferential** Piecing together the above ingredients yields a fundamental pointwise decomposition of the subdifferential of the regularizer gauge \( J \). This decomposability property is at the heart of our results in the rest of the paper.

**Theorem 1** (Decomposability). Let \( J = \gamma_C \) be a bounded gauge. Let \( x \in \mathbb{R}^N \setminus \{0\} \) and \( f_x \in \partial J(x) \). Then the subdifferential of \( J \) at \( x \) reads
\[ \partial J(x) = \left\{ \eta \in \mathbb{R}^N : \eta_T = e_x \quad \text{and} \quad J^o_{f,x}(P_S(\eta - f_x)) \leq 1 \right\} \cdot \]

**First-order minimality condition** Capitalizing on Theorem 1, we are now able to deduce a convenient necessary and sufficient first-order (global) minimality condition of \( (P_\lambda(y)) \) and \( (P_0(y)) \).

**Proposition 5.** Let \( x \in \mathbb{R}^N \), and denote for short \( T = T_x \) and \( S = S_x \). The two following propositions hold.

(i) The vector \( x \) is a global minimizer of \( (P_\lambda(y)) \) if, and only if,
\[ \Phi_T(y - \Phi x) = \lambda e_x \quad \text{and} \quad J^o_{f,x}(\lambda^{-1}\Phi_T(y - \Phi x) - P_S(f_x)) \leq 1 \cdot \]

(ii) The vector \( x \) is a global minimizer of \( (P_0(y)) \) if, and only if, there exists a dual vector \( \alpha \in \mathbb{R}^Q \) such that
\[ \Phi_T^*\alpha = e_x \quad \text{and} \quad J^o_{f,x}(\Phi_S^*\alpha - P_S(f_x)) \leq 1 \cdot \]
2.4. Strong Gauge

In this section, we study a particular subclass of gauges that we dub strong gauges. We start with some definitions.

**Definition 7.** A bounded regularizing gauge $J$ is separable with respect to $T = S^\perp$ if
\[
\forall (x,x') \in T \times S, \quad J(x + x') = J(x) + J(x').
\]

Separability of $J$ is equivalent to the following property on the polar $J^o$.

**Lemma 5.** Let $J$ be a bounded gauge. Then, $J$ is separable w.r.t. to $T = S^\perp$ if, and only if its polar $J^o$ satisfies
\[
J^o(x + x') = \max (J^o(x), J^o(x')), \quad \forall (x,x') \in T \times S.
\]

The decomposability of $\partial J(x)$ as described in Theorem 1 depends on the particular choice of the map $x \mapsto f_x \in \text{ri } \partial J(x)$. An interesting situation is encountered when $e_x \in \text{ri } \partial J(x)$, in which case, one can just choose $f_x = e_x$, hence implying that $f_{S_x} = 0$. Strong gauges are precisely a class of gauges for which this situation occurs.

In the sequel, for a given model subspace $T$, we denote $\tilde{T}$ the set of vectors sharing the same $T$,
\[
\tilde{T} = \{ x \in \mathbb{R}^N : T_x = T \}.
\]

Using positive homogeneity, it is easy to show that $T_{\rho x} = T_x$ and $e_{\rho x} = e_x \forall \rho > 0$. Thus $\tilde{T}$ is a non-empty cone which is contained in $T$ by Proposition 1(iv).

**Definition 8 (Strong Gauge).** A strong gauge on $T$ is a bounded gauge $J$ such that

1. For every $x \in \tilde{T}$, $e_x \in \text{ri } \partial J(x)$.
2. $J$ is separable with respect to $T$ and $S = T^\perp$.

The following result shows that the decomposability property of Theorem 1 has a simpler form when $J$ is a strong gauge.

**Proposition 6.** Let $J$ be a strong gauge on $T_x$. Then, the subdifferential of $J$ at $x$ reads
\[
\partial J(x) = \{ \eta \in \mathbb{R}^N : \eta_{T_x} = e_x \text{ and } J^o(\eta_{S_x}) \leq 1 \}.
\]

When $J$ is in addition a norm, this coincides with the decomposability definition of [7]. Note however that the last part of assertion (ii) in Proposition 4 is an intrinsic property of gauges, while it is stated as an assumption in their definition.

**Example 4 ($\ell^1$-$\ell^2$ norm).** Recall the notations of this example in Section 2.2. Since $e_x = (N(x_b))_{b \in B} \in \text{ri } \partial J(x)$, and the $\ell^1$-$\ell^2$ norm is separable, it is a strong norm according to Definition 8. Thus, its subdifferential at $x$ reads
\[
\partial J(x) = \left\{ \eta \in \mathbb{R}^N : \eta_{T_x} = e_x = (N(x_b))_{b \in B} \text{ and } \max_{b \notin I} |\eta_b| \leq 1 \right\}.
\]

However, except for $N = 2$, $\ell^\infty$ is not a strong gauge.
3. Uniqueness

This section derives sufficient conditions under which the solution of problems \( (P_\lambda(y)) \) and \( (P_0(y)) \) is unique.

We start with the key observation that although \( (P_\lambda(y)) \) does not necessarily have a unique minimizer in general, all solutions share the same image under \( \Phi \).

Lemma 6. Let \( x, x' \) be two solutions of \( (P_\lambda(y)) \). Then,
\[
\Phi x = \Phi x'.
\]

Consequently, the set of the minimizers of \( (P_\lambda(y)) \) is a closed convex subset of the affine space \( x + \text{Ker}(\Phi) \), where \( x \) is any minimizer of \( (P_\lambda(y)) \). This is also obviously the case for \( (P_0(y)) \) since all feasible solutions belong to the affine space \( x_0 + \text{Ker} \Phi \).

3.1. The Strong Null Space Property

The following theorem gives a sufficient condition to ensure uniqueness of the solution to \( (P_\lambda(y)) \) and \( (P_0(y)) \), that we coin \textit{Strong Null Space Property}. This condition is a generalization of the Null Space Property introduced in [12] and popular in \( \ell^1 \) regularization.

Theorem 2. Let \( x \) be a solution of \( (P_\lambda(y)) \) (resp. \( (P_0(y)) \)). Denote \( T = S^\perp = T_x \) the associated model subspace. If the \textit{Strong Null Space Property} holds
\[
\forall \delta \in \text{Ker}(\Phi) \setminus \{0\}, \quad \langle e_x, \delta_T \rangle + \langle P_S(f_x), \delta_S \rangle < J(f_x) + \langle -\delta_S, \delta_S \rangle, \quad (\text{NSP}^S)
\]
then the vector \( x \) is the unique minimizer of \( (P_\lambda(y)) \) (resp. \( (P_0(y)) \)).

This result reduces to the one proved in [15] when \( J \) is decomposable norm pre-composed by a linear operator, where decomposability is intended in the sense of [7]. This is covered by our result when specializing it to a strong gauge \( J \). In such a case, \( (\text{NSP}^S) \) reads
\[
\forall \delta \in \text{Ker}(\Phi) \setminus \{0\}, \quad \langle e_x, \delta_T \rangle < J(-\delta_T).
\]

3.2. Dual Certificates

In this section we derive from \( (\text{NSP}^S) \) a weaker sufficient condition, stated in terms of a dual vector, the existence of which certifies uniqueness.

For some model subspace \( T \), the restricted injectivity of \( \Phi \) on \( T \) plays a central role in the sequel. This is achieved by imposing that
\[
\text{Ker}(\Phi) \cap T = \{0\}. \quad (C_T)
\]
To understand the importance of \( (C_T) \), consider the noiseless case where we want to recover a vector \( x_0 \) from \( y = \Phi x_0 \), whose model subspace is \( T \). Assume that the latter is known. From Proposition 1(iv), \( x_0 \in T \cap \{x : y = \Phi x\} \). For \( x_0 \) to be uniquely
recovered from $y$, $(C_T)$ must be verified. Otherwise, if $(C_T)$ does not hold, then any $x_0 + \delta$, with $\delta \in \text{Ker} \Phi \cap T \setminus \{0\}$, is also a candidate solution. Thus, such objects cannot be uniquely recovered.

We can derive from Theorem 2 the following corollary.

**Corollary 1.** Let $x$ be a solution of $(\mathcal{P}_\lambda(y))$ (resp. $(\mathcal{P}_0(y))$). Assume that there exists a dual vector $\alpha$ such that $\eta = \Phi^* \alpha \in \text{ri} \partial J(x)$, and $(C_T)$ holds where $T = T_x$. Then $x$ is the unique solution of $(\mathcal{P}_\lambda(y))$ (resp. $(\mathcal{P}_0(y))$).

Piecing together Theorem 1 and Corollary 1, one can build a particular dual certificate for $(\mathcal{P}_\lambda(y))$, and then state a sufficient uniqueness explicitly in terms of the decomposable structure of the subdifferential of the regularizing gauge $J$.

**Theorem 3.** Let $x \in \mathbb{R}^N$, and suppose that $f_x \in \text{ri} \partial J(x)$. Assume furthermore that $(C_T)$ holds for $T = T_x$ and let $S = T^\perp$.

(i) If

$$\Phi_T^*(y - \Phi x) = \lambda e_x, \quad (2)$$

$$J_{f_x}^\circ \left( \lambda^{-1} \Phi_T^*(y - \Phi x) - P_S(f_x) \right) < 1. \quad (3)$$

then $x$ is the unique solution of $(\mathcal{P}_\lambda(y))$.

(ii) If there exists a dual certificate $\alpha$ such that

$$\Phi_T^* \alpha = e_x \quad \text{and} \quad J_{f_x}^\circ (\Phi_T^* \alpha - P_S(f_x)) < 1.$$

then $x$ is the unique solution of $(\mathcal{P}_0(y))$.

4. **Piecewise Regular Gauges**

Until now, except of being bounded (i.e. full domain), no other assumption was imposed on the regularizing gauge $J$. But, toward the goal of studying robust recovery by solving $(\mathcal{P}_\lambda(y))$, more will be needed. This is the main reason underlying the introduction of a subclass of bounded gauges $J$ for which the mappings $x \mapsto e_x$, $x \mapsto P_S(f_x)$ and $x \mapsto J_{f_x}^\circ$ exhibit local regularity.

4.1. **Piecewise Regular Gauges**

**Definition 9** (Piecewise Regular Gauge). A bounded gauge $J$ is said to be piecewise regular (PRG for short) at $x \in \mathbb{R}^N$, with respect to the mapping $x \mapsto f_x \in \text{ri} \partial J(x)$ and $\Gamma$ a coercive gauge bounded on $T_x = T = S^\perp$, if there exist three non-negative reals $\nu_x, \mu_x, \tau_x$ and a real $\xi_x$ such that for every $x' \in T$ with $\Gamma(x - x') \leq \nu_x$, one has
The gauge $J$ is strongly piecewise regular at $x \in \mathbb{R}^N$ if $J$ is piecewise regular at $x$ and strong (Definition 8) with respect to $T$.

In plain words, (4), (5) and (6) amount to imposing that $J$ is sufficiently regular (Lipschitzian-like) on $\tilde{T}$. Recall from Section 2.4 that $\tilde{T}$ is a non-empty cone and $e^\rho_x = e_x$ for all $\rho > 0$. Thus we have $\mu_x^x = \rho \mu_x$. Moreover, one can always impose $\mu_x \nu_x \leq C$ for some global constant $C$ (but of course $\nu_x$ can be smaller and even zero).

Many well-studied gauges are strongly piecewise regular. One can for instance think of the $\ell^1$-norm, the $\ell^1 - \ell^2$-norm and the nuclear norm. The analysis-$\ell^1$ regularization or $\ell^\infty$-norm are however not strong PRG. Piecewise regularity of these examples is investigated in details in Section 6.

4.2. Operations Preserving Piecewise Regularity

Piecewise regularity is preserved under addition and pre-composition by a linear operator. It is worth observing that strong piecewise regularity is however not preserved under the same operations. More precisely, the composition of a strong gauge with a linear operator is not strong anymore, nor is the gauge of the sum of two strong gauges.

4.2.1. Addition

The following proposition determines the model subspace and the antipromoting gauge of the sum of two gauges $H = J + G$ in terms of those associated to $J$ and $G$.

**Proposition 7.** Let $J$ and $G$ be two bounded gauges. Denote $T^J$ and $e^J$ (resp. $T^G$ and $e^G$) the model subspace and vector at a point $x$ corresponding to $J$ (resp. $G$). Then the subdifferential of $H$ has the decomposability property with

(i) $T^H = T^J \cap T^G$, or equivalently $S^H = (T^H)^\perp = \text{span} \left( S^J \cup S^G \right)$.

(ii) $e_H = P_{T^H} (e^J + e^G)$.

(iii) Moreover, let $J^J_x$ and $G^G_x$ denote the antipromoting gauges for the pairs $(J, f^J_x \in \partial J(x))$ and $(G, f^G_x \in \partial G(x))$, correspondingly. Then, for the particular choice of

$$f^H_x = f^J_x + f^G_x$$
we have $f^H_x \in \ri \partial H(x)$, and for a given $\eta \in S^H$, the antipromoting gauge of $H$
reads
\[ H^H_\eta(\eta) = \inf_{\eta_1 + \eta_2 = \eta} \max(J^\eta_{f_1}(\eta_1), G^\eta_{f_2}(\eta_2)). \]

We now establish piecewise regularity of the sum with the decomposability property
dictated by Proposition 7.

Proposition 8. If $J$ and $G$ are piecewise regular gauges at $x$ with the corresponding
parameters $(\Gamma^J, \nu^J_x, \mu^J_x, \tau^J_x, \xi^J_x)$ and $(\Gamma^G, \nu^G_x, \mu^G_x, \tau^G_x, \xi^G_x)$, then $H = J + G$ is also
piecewise regular at $x$, for the choice $f^H_x = f^J_x + f^G_x$ and $\Gamma^H = \max(\Gamma^J, \Gamma^G)$, with the
parameters
\[
\begin{align*}
\nu^H_x &= \min(\nu^J_x, \nu^G_x) \\
\mu^H_x &= \mu^J_x + \mu^G_x + \mu^J_x M_{\Gamma^J \cap \Gamma^G}(P_{T^H}) + \mu^G_x M_{\Gamma^G \cap \Gamma^J}(P_{T^H}) \\
\tau^H_x &= \tau^J_x + \tau^G_x + \mu^J_x M_{\Gamma^J \cap \Gamma^G}(P_{S^H \cap T^G}) + \mu^G_x M_{\Gamma^G \cap \Gamma^J}(P_{S^H \cap T^G}) \\
\xi^H_x &= \max(\xi^J_x, \xi^G_x).
\end{align*}
\]

4.2.2. Pre-composition by a Linear Operator

Gauges of the form $J_0 \circ D^*$, where $J_0$ is a bounded regularizing gauge, correspond to
the so-called analysis-type regularizers. The most popular example in this class if the
total variation where $J_0$ is the $\ell^1$ or the $\ell^1 - \ell^2$ norm, and $D^* = \nabla$ is a finite difference
discretization of the gradient.

In the following, we denote $T = T_x = S^L_x$ and $e = e_x$ the subspace and vector
in the decomposition of the subdifferential of $J$ at a given $x \in \mathbb{R}^N$. Analogously,
$T_0 = S^L_0$ and $e_0$ are those of the gauge $J_0$ at $D^* x$. The following proposition details
the decomposability structure of analysis-type gauges.

Proposition 9. Let $J_0$ be a bounded gauge. With the above notation, the subdifferential
of the analysis gauge $J = J_0 \circ D^*$, which is also bounded, has the decomposability
property with
\[
\begin{align*}
(i) &\quad T = \text{Ker}(D^* S_0), \text{ or equivalently } S = \text{Im}(D S_0). \\
(ii) &\quad e = P_T D e_0. \\
(iii) &\quad \text{Moreover, let } J^\circ_{0, f_0, D^*} \text{ denote the antipromoting gauge for the pair } (J_0, f_0, D^* x \in \ri \partial J_0(x)). \text{ Then, for the particular choice of}
\end{align*}
\]
\[ f_x = D f_{0, D^* x} \]
\[ \text{we have } f_x \in \ri \partial J(x), \text{ dom } J^\circ_x = S \text{ and for every } \eta \in S
\]
\[ J^\circ_x(\eta) = \inf_{z \in \text{Ker}(D S_0)} J^\circ_{0, f_0, D^*}(D^*_0 \eta + z). \]

The infimum can be equivalently taken over $\text{Ker}(D) \cap S_0$. 

18
Capitalizing on these properties, we now establish that an analysis gauge \( J = J_0 \circ D^* \), where \( J_0 \) is a PRG, is also piecewise regular.

**Proposition 10.** If \( J_0 \) is a bounded piecewise regular gauge at \( u = D^* x \) with the parameters \((\Gamma_0, \nu_{0,u}, \mu_{0,u}, \tau_{0,u}, \xi_{0,u})\), then \( J = J_0 \circ D^* \) is piecewise regular at \( x \), with the choice \( f_x = Df_{0,u} \) and \( \Gamma \) any bounded coercive gauge on \( T \), with the parameters

\[
\begin{align*}
\nu_x &= \frac{1}{\mathcal{M}_{\Gamma_0}(D^*)} \nu_{0,u} \\
\mu_x &= \mu_{0,u} \mathcal{M}_{\Gamma_0}(P_T D) \mathcal{M}_{\Gamma_0}(D^*) \\
\tau_x &= \left( \tau_{0,u} \mathcal{M}_{J_0^{+,-}, f_{0,u}} (D^* P_S D) + \mu_{0,u} \mathcal{M}_{\Gamma_0, J_0^{+,-}, f_{0,u}} (D^* P_S D) \right) \mathcal{M}_{\Gamma_0}(D^*) \\
\xi_x &= \xi_{0,u} \mathcal{M}_{\Gamma_0}(D^*).
\end{align*}
\]

5. Exact Model Selection and Identifiability

In this section, we state our main recovery guarantee, which asserts that under appropriate conditions, \((P_\lambda(y)) \) with a piecewise regular gauge \( J \) has a unique solution \( x^* \) whose model subspace \( T_{x^*} = T_{x_0} \), even in presence of noise. Put differently, regularization by \( J \) is able to select the correct model subspace underlying \( x_0 \).

Beside condition \((C_{T_x})\) stated above, the following Identifiability Criterion will play a pivotal role.

**Definition 10.** For \( x \in \mathbb{R}^N \) such that \((C_{T_x}) \) holds, we define the Identifiability Criterion at \( x \) as

\[
\text{IC}(x) = J^*_{f_x} (\Phi_{S_x}^{+,-} \phi_{T_x}^{+,-} e_x - P_{S_x} f_x).
\]

Note that if \( J \) is a strong gauge on \( T \), then it becomes \( \text{IC}(x) = J^* (\Phi_{S_x}^+ \phi_{T_x}^+ e_x) \).

The Identifiability Criterion clearly brings into play the promoted subspace \( T_{x_0} \) and the interaction between the restriction of \( \Phi \) to \( T_{x_0} \) and \( S_{x_0} \). It is a generalization of the irrepresentable condition that has been studied in the literature for some popular regularizers, including the \( \ell_1 \)-norm [17], analysis-\( \ell_1 \) [40], and \( \ell_1-\ell_2 \) [1]. See Section 6 for a comprehensive discussion.

5.1. Noiseless Identifiability

We begin with the noiseless case, i.e. \( w = 0 \) in (1). It turns out that in such a setting, \( \text{IC}(x_0) < 1 \) is a sufficient condition for identifiability without any other particular assumption on the bounded gauge \( J \), such as piecewise regularity. By identifiability, we mean the fact that \( x_0 \) is the unique solution of \((P_0(y))\).

**Theorem 4.** Let \( x_0 \in \mathbb{R}^N \) and \( T = T_{x_0} \). We assume that \((C_T) \) holds and \( \text{IC}(x_0) < 1 \). Then \( x_0 \) is the unique solution of \((P_0(y))\).
5.2. Exact Model Selection

It turns out that even in presence of noise in the measurements $y$ according to (1), condition $\text{IC}(x_0) < 1$ characterizes also those vectors where $(\mathcal{P}_\lambda(y))$ with piecewise regular gauges provides a robust selection of the model subspace of $x_0$. Our main contribution is the following theorem.

**Theorem 5.** Let $x_0 \in \mathbb{R}^N$ and $T = T_{x_0}$. We suppose that $J$ is a piecewise regular gauge $x_0$ with the corresponding parameters $(\Gamma, \nu_{x_0}, \mu_{x_0}, \tau_{x_0}, \xi_{x_0})$. Assume that (C-T) holds and $\text{IC}(x_0) < 1$. Then there exist positive constants $(A_T, B_T)$ that solely depend on $T$ and a constant $C(x_0)$ such that if $w$ and $\lambda$ obey

$$
\frac{A_T}{1 - \text{IC}(x_0)} ||w|| \leq \lambda \leq \nu_{x_0} \min (B_T, C(x_0))
$$

the solution $x^*$ of $(\mathcal{P}_\lambda(y))$ with noisy measurements $y$ is unique, and satisfies $T_{x^*} = T$. Furthermore, one has

$$
||x_0 - x^*|| = O\left( \max(||w||, \lambda) \right).
$$

Clearly this result asserts that exact recovery of $T_{x_0}$ from noisy partial measurements is possible with the proviso that the regularization parameter $\lambda$ lies in the interval (7). The value $\lambda$ should be large enough to reject noise, but small enough to recover the entire subspace $T_{x_0}$. In order for the constraint (7) to be non-empty, the noise-to-signal level $||w||/\nu_{x_0}$ should be small enough, i.e.

$$
\frac{||w||}{\nu_{x_0}} \leq \frac{1 - \text{IC}(x_0)}{A_T} \min (B_T, C(x_0)).
$$

The constant $C(x_0)$ involved in this bound depends on $x_0$ and has the form

$$
C(x_0) = \frac{1 - \text{IC}(x_0)}{\xi_{x_0} \nu_{x_0}} H \left( \frac{D_T \mu_{x_0} + \tau_{x_0}}{\xi_{x_0}} \right)
$$

where $H(\beta) = \frac{\beta + 1/2}{E_T \beta} \varphi \left( \frac{2\beta}{(\beta + 1)^2} \right)$ and $\varphi(u) = \sqrt{1 + u} - 1$.

The constants $(D_T, E_T)$ only depend on $T$. $C(x_0)$ captures the influence of the parameters $\pi_{x_0} = (\mu_{x_0}, \tau_{x_0}, \xi_{x_0})$, where the latter reflect the geometry of the regularizing gauge $J$ at $x_0$. More precisely, the larger $C(x_0)$, the more tolerant the recovery is to noise. Thus favorable regularizers are those where $C(x_0)$ is large, or equivalently where $\pi_{x_0}$ has small entries, since $H$ is a strictly decreasing function.

6. Examples of Piecewise Regular Gauges

6.1. Synthesis $\ell_1$ Sparsity

The regularized problem $(\mathcal{P}_\lambda(y))$ with $J(x) = ||x||_1 = \sum_{i=1}^N |x_i|$ promotes sparse solutions. It goes by the name of Lasso [38] in the statistical literature, and Basis Pursuit DeNoising (or Basis Pursuit in the noiseless case) [10] in signal processing.
The $\ell^1$ norm is a PRG. The norm $J(x) = |x|_1$ is a symmetric (bounded) strong gauge. More precisely, we have the following result.

**Proposition 11.** $J = \| \cdot \|_1$ is a symmetric strong gauge with

$$T_x = \{ \eta \in \mathbb{R}^N : \forall j \not\in I, \eta_j = 0 \}, \quad S_x = \{ \eta \in \mathbb{R}^N : \forall i \in I, \eta_i = 0 \},$$

$$e_x = \text{sign}(x), \quad f_x = e_x, \quad J^+_x = \| \cdot \|_\infty + \delta S_x,$$

where $I = I(x) = \{ i : x_i \neq 0 \}$. Moreover, it is strongly piecewise regular with

$$\Gamma = \| \cdot \|_\infty, \quad \nu_x = (1 - \delta)\min_{i \in I} |x_i|, \delta \in [0,1] \quad \text{and} \quad \mu_x = \tau_x = \xi_x = 0.$$

**Relation to previous work.** The theoretical recovery guarantees of $\ell^1$-regularization have been extensively studied in the recent years. There is of course a huge literature on the subject, and covering it comprehensively is beyond the scope of this paper. In this section, we restrict our overview to those works pertaining to ours, i.e., sparsity pattern recovery in presence of noise.

For instance, an identifiability criterion was introduced in [17]. Let $s \in \{-1,0,+1\}^N$ and $I$ its support. Suppose that $\Phi(I)$ has full column rank, which is precisely $(C_T)$ in this case. The synthesis identifiability criterion $IC_{\ell^1}$ of $s$ is defined as

$$IC_{\ell^1}(s) = \| \Phi_{(I,I)}^* \Phi_{(I,I)}^+ s(I) \|_\infty = \max_{j \in I^c} |\langle \Phi_j, \Phi_{(I,I)}^+ s(I) \rangle|.$$ 

From Definition 10 and Proposition 11, one immediately recognizes that $IC_{\ell^1}(\text{sign}(x)) = IC(x)$. The condition $IC_{\ell^1}(\text{sign}(x)) < 1$, also known as the irrepresentable condition in the statistical literature, was proposed [17] for exact support (and sign) pattern recovery with $\ell_1$-regularization from partial noisy measurements. In this respect, this work can then be viewed as a special instance of ours, as Theorem 5 in this case ensures recovery of the support pattern.

**6.2. Analysis $\ell^1$ Sparsity**

Let $D = (d_i)_{i=1}^P$ be a collection of $P$ atoms $d_i \in \mathbb{R}^N$. The analysis semi-norm associated to $D$ is $J(x) = \|D^* x\|_1 = \sum_{i=1}^P |\langle d_i, x \rangle|$. Obviously, the synthesis $\ell^1$-regularization corresponds to $D = \text{Id}$. Popular examples of analysis-type $\ell^1$ semi-norms include for instance the discrete anisotropic total variation [35], the Fused Lasso [39] and shift invariant wavelets [36].

**The analysis $\ell^1$ semi-norm is a PRG.** The semi-norm $J(x) = \|D^* x\|_1$ is a symmetric piecewise regular gauge. This is formalized in the following proposition whose proof is a straightforward application of Proposition 9, Proposition 10 and Proposition 11.
Proposition 12. $J = \|D^* \cdot \|_1$ is a symmetric (bounded) gauge with

$$T_x = \text{Ker}(D^*_{(I x)}) = \{ \eta \in \mathbb{R}^N : \forall j \notin I, (d_j, \eta_j) = 0 \}, \quad S_x = \text{Im}(D_{I^c}),$$

$$e_x = P_{\text{Ker}(D^*_x)} D \text{sign}(D^* x), \quad f_x = D \text{sign}(D^* x),$$

$$J^*_x(I) = \inf_{\eta \in \text{Ker}(D^*_x)} \| D^* x \eta + z \|_\infty, \quad \text{for} \quad \eta \in S_x,$$

where $I = I(x) = \{ i : (d_i, x_i) \neq 0 \}$. Moreover, it is piecewise regular with parameters

$$\nu_x = (1 - \delta) \min_{i \in I} |(d_i, x_i)|, \quad \delta \in [0, 1] \quad \text{and} \quad \mu_x = \tau_x = \xi_x = 0.$$

Relation to previous work. Some insights on the relation and distinction between synthesis- and analysis-based sparsity regularizations were first given in [14]. When $D$ is orthogonal, and more generally when $D$ is square and invertible, the two forms of regularization are equivalent in the sense that the set of minimizers of one problem can be retrieved from that of an equivalent form of the other through a bijective change of variable. It is only recently that theoretical guarantees of $\ell^1$-analysis sparse regularization have been investigated, see [40] for a comprehensive review. Among such a work, the authors in [26] propose a null space property for identifiability in the synthesis-based case. The most relevant work to ours here is that of [40], where the authors prove exact robust recovery of the support and sign patterns under conditions that are a specialization of those in Theorem 5.

More precisely, let $I$ be the support of $D^* x_0$, and $s$ its sign vector. Denote $T = T_{x_0} = S^+ = \text{Ker}(D^*_{I^c})$, $e_{x_0} = \text{sign}(D^* x_0) = s$, $e = e_{x_0} = P_T D s$, $f = f_{x_0} = D s$. From Definition 10 and Proposition 12, the criterion $\text{IC} (x_0)$ in this case takes the form

$$\text{IC} (x_0) = J^*_x (\Phi^*_S \Phi^*_T^{+*} P_T D s - P_S D s) = \inf_{z \in \text{Ker}(D^*_x)} \| D^* x \Phi^*_S \Phi^*_T^{+*} P_T D s + z \|_\infty$$

$$= \inf_{z \in \text{Ker}(D^*_x)} \| D^* x ( (I - P_T) \Phi^* \Phi P_T (\Phi^*_S \Phi^*_T^{+*})^{-1} P_T - P_S ) D s + z \|_\infty$$

$$= \inf_{z \in \text{Ker}(D^*_x)} \| D^* x ( \Phi^* \Phi P_T (\Phi^*_T^{+*} \Phi^*_T)^{-1} P_T - (P_T + P_S) ) D s + z \|_\infty$$

$$= \inf_{z \in \text{Ker}(D^*_x)} \| D^* x ( \Phi^* \Phi P_T (\Phi^*_T^{+*} \Phi^*_T)^{-1} P_T - (I - \Phi^*_T^{+*} \Phi^*_T)^{-1} \Phi^*_T^{+*} \Phi^*_T - (I - \Phi^*_T^{+*} \Phi^*_T)^{-1} \Phi^*_T^{+*} \Phi^*_T ) D s + z \|_\infty.$$

Introducing $U$ as a matrix whose columns form a basis of $T$, $\text{IC}(x_0)$ can be equivalently rewritten

$$\text{IC}(x_0) = \inf_{z \in \text{Ker}(D^*_x)} \| D^* x ( \Phi^* \Phi A^{[T^*]} - I d ) D_{(I)} \xi_d (I) + z \|_\infty,$$

where $A^{[T^*]} = U (U^* \Phi^* \Phi U)^{-1} U^*$. We recover exactly the expression of the $\text{IC}_{\ell^1 - D}$ introduced in [40].
6.3. \( \ell^\infty \) Antisparsity Regularization

Regularization by the \( \ell^\infty \)-norm corresponds to taking \( J(x) = \|x\|_\infty = \max_{1 \leq i \leq N} |x_i| \). It plays a prominent role in a variety of applications including approximate nearest neighbor search [21] or vector quantization [24]; see also [37] and references therein.

The \( \ell^\infty \)-norm is a PRG. The norm \( J(x) = \|x\|_\infty \) is a symmetric piecewise regular gauge, but unlike the \( \ell^1 \)-norm, it is not strongly so (except for \( N = 2 \)). Therefore, in the following proposition, we rule out the trivial case \( x = 0 \).

**Proposition 13.** \( J = \|\cdot\|_\infty \) is a symmetric (bounded) gauge with

\[
S_x = \{ \eta : \eta_{I^c} = 0 \quad \text{and} \quad \langle \eta_I, s(I) \rangle = 0 \}, \quad T_x = \{ \alpha : \alpha_{I^c} = \rho s(I) \quad \text{for} \quad \rho \in \mathbb{R} \},
\]

\[e_x = \frac{s}{|I|}, \quad f_x = e_x, \quad J_f^\infty(\eta) = \max_{i \in I} (-|I|s_i\eta_i)_+ \quad \text{for} \quad \eta \in S_x,
\]

where \( s = \text{sign}(x) \) and \( I = I(x) = \{ i : |x_i| = \|x\|_\infty \} \). Moreover, it is piecewise regular with

\[\Gamma = \|\cdot\|_1, \quad \nu_x = (1 - \delta)(\|x\|_\infty - \max_{j \notin I} |x_j|), \delta \in [0, 1] \quad \text{and} \quad \mu_x = \tau_x = \xi_x = 0.\]

**Relation to previous work.** In the noiseless case, i.e. \((P_0(y))\) with \( J = \|\cdot\|_\infty \), theoretical analysis of \( \ell^\infty \)-regularization goes back to the 70’s through the work of [6]. [24] provided results that characterize signal representations with small (but not necessarily minimal) \( \ell^\infty \)-norm subject to linear constraints. A necessary and sufficient condition for a vector to be the unique minimizer of \((P_0(y))\) is derived in [25]. The work of [13] analyzes recovery guarantees by \( \ell^\infty \)-regularization in a noiseless random sensing setting.

The authors in [37] analyzed the properties of solutions obtained from a constrained form of \((P_\lambda(y))\) with \( J = \|\cdot\|_\infty \). In particular, they improved and generalized the bound of [24] on the \( \ell^\infty \) of the solution.

The work of [3, 28] studies robust recovery with regularization using a subclass of polyhedral norms obtained by convex relaxation of combinatorial penalties. Although this covers the case of the \( \ell^\infty \)-norm, their notion of support is however, completely different from ours. We will come back to this work with a more detailed discussion in Section 6.5.

6.4. Block/Group Sparsity Regularization

Let’s recall from Section 2.2 that \( B \) is a uniform disjoint partition of \( \{1, \cdots, N\} \),

\[
\{1, \ldots, N\} = \bigcup_{b \in B} b, \quad b \cap b' = \emptyset, \quad \forall b \neq b'.
\]

The \( \ell^1 - \ell^2 \) norm of \( x \) is

\[J(x) = \|x\|_B = \sum_{b \in B} |x_b|.
\]
This prior has been advocated when the signal exhibits a structured sparsity pattern where the entries are assumed to be clustered in few non-zero groups; see for instance [4, 44]. The corresponding regularized problem \( (P_{\lambda}(y)) \) is known as the group Lasso.

The \( \ell^1-\ell^2 \) norm is a PRG. The \( \ell^1-\ell^2 \) norm is a symmetric strongly piecewise regular gauge.

**Proposition 14.** The \( \ell^1-\ell^2 \) norm associated to the partition \( \mathcal{B} \) is a symmetric (bounded) strong gauge with

\[
T_x = \{ \eta : \forall j \notin I, \eta_j = 0 \}, \quad S_x = \{ \eta : \forall i \in I, \eta_i = 0 \},
\]

\[
e_x = (N(x_b))_{b \in \mathcal{B}}, \quad f_x = e_x, \quad J^x = \| \cdot \|_{\infty,2} + \epsilon_{S_x},
\]

where \( I = I(x) = \{ b : x_b \neq 0 \} \), and \( N(a) = a / \| a \| \) if \( a \neq 0 \), and \( N(0) = 0 \). Moreover, it is strongly piecewise regular with

\[
\Gamma = \| \cdot \|_{\infty,2}, \quad \nu_x = (1 - \delta) \min_{b \in I} \| x_b \|, \quad \delta \in [0,1], \quad \mu_x = \frac{\sqrt{2}}{\nu_x} \quad \text{and} \quad \tau_x = \xi_x = 0.
\]

**Relation to previous work.** Theoretical guarantees of the group Lasso have been investigated by several authors under different performance criteria; see e.g. [44, 34, 1, 11, 23, 43] to cite only a few. In particular, the author in [1] studies the asymptotic group selection consistency of the group Lasso in the overdetermined case, under a group irrepresentable condition. This condition also appears in noiseless identifiability in the work of [7]. The group irrepresentable condition is nothing but the specialization to the group Lasso of our condition based on \( IC(x_0) \). Indeed, using Definition 10 and Proposition 14, and assuming that \( \Phi(I) \) is full column rank (i.e. \( \mathcal{C}_T \) is fulfilled), \( IC(x_0) \) reads

\[
IC(x_0) = \left\| \Phi_{(I')}^* \Phi(I) \left( \frac{x_b}{\| x_b \|} \right)_{b \in I} \right\|_{\infty,2}.
\]

(8)

It is worth mentioning that the discrete isotropic total variation in \( d \)-dimension, \( d \geq 2 \), can be viewed as an analysis-type \( \ell^1 - \ell^2 \) semi-norm. Piecewise regularity and theoretical recovery guarantees with such a regularization can be retrieved from those of this paper using the results on the pre-composition rule given in Section 4.2.2.

**6.5. Polyhedral Regularization**

A particular case of analysis priors are polyhedral gauges, that are in general not piecewise regular. The \( \ell^1 \) and \( \ell^\infty \) norms are special cases of polyhedral priors (\( \ell^1 \) being strongly piecewise regular, while \( \ell^\infty \) being only piecewise regular). There are two alternative ways to define a polyhedral gauge. The \( H \)-representation encodes the gauge through the hyperplanes that support the polygonal facets of its unit level set. The \( V \)-representation encodes the gauge through the vertices that are the extreme points of this unit level set. We focus here on the \( H \)-representation.
A polyhedral gauge is a PRG. A polyhedral gauge in the $H$-representation is defined as

$$J(x) = \max_{1 \leq i \leq N_H} \langle x, h_i \rangle_+ = J_0(H^*x) \quad \text{where} \quad J_0(u) = \max_{1 \leq i \leq N_H} (u_i)_{++},$$

and we have defined $H = (h_i)_{i=1}^{N_H} \in \mathbb{R}^{N \times N_H}$.

Such a polyhedral gauge can also be thought as an analysis gauge as considered in Section 4.2.2 by identifying $D = H$. One can then characterize decomposability and piecewise regularity of $J_0$ and then invoke Proposition 9 and 10 to derive those of $J$. This is what we are about to do. In the following, we denote $(a^i)_{1 \leq i \leq N_H}$ the standard basis of $\mathbb{R}^{N_H}$.

**Proposition 15.** $J_0(u) = \max_{1 \leq i \leq N_H} (u_i)_{++}$ is a (bounded) gauge and,

- If $u_i \leq 0, \forall i \in \{1, \cdots, N_H\}$, then
  $$S_u = \text{span} \{a^i \}_{i \in I_0}, \quad T_u = \text{span} \{a^i \}_{i \notin I_0},$$
  $$e_u = 0, \quad f_u = \mu \sum_{i \in I_0} a^i, \quad \text{for any } 0 < \mu < 1,$$
  $$J_{f_u}^0(\eta) = \inf_{\tau \geq \max_{i \in I_0} (-\eta_i)_+ / \mu} \max_{i \in I_0} (\tau \mu |I_0| + \sum_{i \in I_0} \eta_i, \tau) \quad \text{for } \eta \in S_u,$$
  where $I_0 = \{i \in \{1, \cdots, N_H\} : u_i = J_0(u) = 0\}$.

- If $\exists i \in \{1, \cdots, N_H\}$ such that $u_i > 0$, then
  $$S_u = \left\{ \eta : \eta_{(I_+)} = 0 \quad \text{and} \quad \langle \eta_{(I_+)}, s_{(I_+)} \rangle = 0 \right\},$$
  $$T_u = \left\{ \alpha : \alpha_{(I_+)} = \mu s_{(I_+)} \quad \text{for} \quad \mu \in \mathbb{R} \right\},$$
  $$e_u = \frac{s}{|I_+|}, \quad f_u = e_u, \quad J_{f_u}^0(\eta) = \max_{i \in I_+} (-|I_+| \eta_i)_+ \quad \text{for} \quad \eta \in S_u,$$
  where
  $$s = \sum_{i \in I_+} a^i \quad \text{and} \quad I_+ = \{i \in \{1, \cdots, N_H\} : u_i = J_0(u) \quad \text{and} \quad u_i > 0\}.$$

Moreover, it is piecewise regular with parameters (assuming $I_+ \neq \emptyset$)

$$\nu_u = (1 - \delta) \left( \max_{i \in I_+} u_i - \max_{j \notin I_+, u_j > 0} u_j \right), \delta \in [0, 1] \quad \text{and} \quad \mu_u = \tau_u = \xi_u = 0.$$

**Relation to previous work.** As stated in the case of $\ell^\infty$-norm, the work of of [3] considers robust recovery with a subclass of polyhedral norms but his notion of support is different from ours. The work [30] studies numerically some polyhedral regularizations. Again in a compressed sensing scenario, the work of [9] studies a subset of polyhedral

25
regularizations to get sharp estimates of the number of measurements for exact and ℓ₂-stable recovery. The closest work to ours is that reported in [41], where theoretical recovery guarantees by polyhedral regularization were provided under similar conditions to ours and with the same notion of support as considered above. However only bounded coercive polyhedral gauges were considered there.

6.6. Nuclear Norm Regularization

The nuclear norm, or trace norm, has been proposed as an effective convex relaxation for rank minimization problems to provably recover low-rank matrices [8, 32]. The nuclear norm of a \( N_1 \times N_2 \) rank-\( r \) matrix \( x \) is defined as

\[
J(x) = \|\text{diag}(\Sigma)\|_1,
\]

where \( x = U\Sigma V^* \) is a reduced singular value decomposition (SVD) of \( x \), with \( \text{diag}(\Sigma) = (\sigma_i)_{1 \leq i \leq r} \) the singular values, \( U \) \( (N_1 \times r) \) and \( V \) \( (N_2 \times r) \) are the matrices of left and right singular vectors.

The nuclear norm is a PRG. In the following, we show that the nuclear norm is a symmetric strongly piecewise regular gauge.

**Proposition 16.** The nuclear norm is a symmetric strong gauge with

\[
S_x = \left\{ U_{\perp}^* C V_{\perp} \mid C \in \mathbb{R}^{(N_1-r) \times (N_2-r)} \right\},
\]

\[
T_x = \left\{ UA^* + BV^* \mid A \in \mathbb{R}^{N_2 \times r}, B \in \mathbb{R}^{N_1 \times r} \right\} = \left\{ Z \in \mathbb{R}^{(N_1-r) \times (N_2-r)} : U_{\perp}^* Z V_{\perp} = 0 \right\},
\]

\[
e_x = UV^*, \quad f_x = e_x, \quad J^\circ(x) = \max_i \sigma_i + \iota_{S_x},
\]

where \( U_{\perp}, V_{\perp} \) span the orthogonal of the ranges of \( U, V \). Moreover, it is strongly piecewise regular with parameters

\[
\nu_x = \frac{1}{4} \min_{1 \leq i \leq r} |\sigma_i|, \quad \mu_x = \frac{1}{\nu_x} \quad \text{and} \quad \tau_x = \xi_x = 0.
\]

I can be observed that \( \dim(T_x) = r(N_1 + N_2 - r) \) and \( \dim(S_x) = N_1 N_2 - \dim(T_x) = N_1 N_2 - r(N_1 + N_2) + r^2 \).

**Relation to previous work.** The work in [2] defines an irrepresentability condition for the nuclear norm. This irrepresentability condition is assumed in [2] to establish asymptotic rank consistency of nuclear norm minimization in the overdetermined case. Similarly to (8), this condition can be shown to be equivalent to our condition \( \text{IC}(x_0) < 1 \), when specialized to the case of the nuclear norm. Note also that [2] provides a proof of the PRG property of the nuclear norm (Proposition 16). In their unified framework, the work [32] derives tight bounds on the number of Gaussian measurements needed for exact and robust recovery by nuclear norm minimization. The work of [32] complements these results, using the irrepresentable condition tailored to the nuclear norm, to get tight bounds for noiseless identifiability.

Let us also point out that the recent work of [19] considers an analysis-type form of the nuclear norm, the so-called trace Lasso. However no recovery guarantees (with or
without noise) were given. In fact, combining Proposition 16 and the results on the pre-composition rule given in Section 4.2.2, one can establish piecewise regularity and derive theoretical recovery guarantees for the trace Lasso.

7. Conclusion

In this paper, we introduced the notion of piecewise regular gauge as a generic convex regularization framework, and presented a unified view of to derive exact and robust recovery guarantees for a large class of convex regularizations. In particular, we provided sufficient conditions ensuring uniqueness of the minimizer to both \((P_\lambda(y))\) and \((P_0(y))\), whose byproduct is to guarantee exact recovery of the original object \(x_0\) in the noiseless case by solving \((P_0(y))\). In presence of noise, sufficient conditions were given to certify exact recovery of the model subspace underlying \(x_0\). As shown in the considered examples, these results encompass a variety of cases extensively studied in the literature (e.g. \(l^1\), analysis \(l^1\), \(l^1 - l^2\), nuclear norm), as well as less popular ones (inf, polyhedral).

Appendices

A. Proofs of Section 2

Proof of Lemma 1. (i)-(iii) are obtained from [20, Theorem V.1.2.5]. (iv) is obtained by combining [20, Corollary V.1.2.6 and Proposition IV.3.2.5]. (v): the second statement follows by combining (iii)-(iv), while the first part is the second one written in dom \(\gamma_C = \text{aff } C = \text{span } C\) since \(0 \in C\).

Proof of Lemma 2. (i) follows from [33, Theorem 15.1]. (ii) [33, Corollary 15.1.1] or [20, Proposition V.3.2.4]. (iii) [33, Corollary 15.1.2] or [20, Proposition V.3.2.5].

Proof of Lemma 3. We have from Lemma 2 and calculus rules on support functions,

\[
\gamma(C_1 + C_2)^o = \sigma_{C_1 + C_2} = \sigma_{C_1} + \sigma_{C_2}.
\]

Thus

\[
(C_1 + C_2)^o = \{u : \sigma_{C_1}(u) + \sigma_{C_2}(u) \leq 1\}.
\]
This yields that

$$\gamma_{C_1+C_2}(x) = \sigma_{\sigma_{C_1} + \sigma_{C_2}}(x)$$

$$= \sigma_{\sigma_{C_1}(u) + \sigma_{C_2}(u)} \leq 1$$

$$= \sup_{\sigma_{C_1}(u) + \sigma_{C_2}(u) \leq 1} \langle u, x \rangle$$

$$= \sup_{\rho \in [0,1]} \sup_{\sigma_{C_1}(u) \leq \rho, \sigma_{C_2}(u) \leq 1 - \rho} \langle u, x \rangle$$

$$= \sup_{\rho \in [0,1]} \sigma_{\sigma_{C_1}(u) \leq \rho} \vee \sigma_{\sigma_{C_2}(u) \leq 1 - \rho} \sigma(x)$$

$$= \sup_{\rho \in [0,1]} \rho \sigma_{C_1} \vee (1 - \rho) \sigma_{C_2}(x)$$

$$= \sup_{\rho \in [0,1]} \rho \gamma_{C_1} \vee (1 - \rho) \gamma_{C_2}(x),$$

which is the first assertion.

The last identity can be rewritten

$$\gamma_{C_1+C_2}(x) = \inf_{\rho \in [0,1]} \sup_{x_1 + x_2 = x} \rho \gamma_{C_1}(x_1) + (1 - \rho) \gamma_{C_2}(x_2).$$

Under the boundedness and continuity assumption of the lemma, the objective in the sup inf is a continuous bounded concave-convex function on $[0,1] \times \{(x_1, x_2) : x_1 + x_2 = x \}$. Since the latter sets are non-empty, closed and convex, and $[0,1]$ is obviously bounded, we have from using [33, Corollary 37.3.2]

$$\gamma_{C_1+C_2}(x) = \inf_{z \in \mathbb{R}^N} \sup_{\rho \in [0,1]} \rho \gamma_{C_1}(z) + (1 - \rho) \gamma_{C_2}(x - z)$$

$$= \inf_{z \in \mathbb{R}^N} \max(\gamma_{C_1}(z), \gamma_{C_2}(x - z)).$$

Proof of Lemma 4. It is immediate to see that $D(C)$ is a closed convex set containing the origin. Moreover, we have $\text{Im}(D^*) \cap \text{dom}(\sigma_C) \neq \emptyset$, since the origin is in both of them. Thus, using [20, Theorem X.2.1.1] and Lemma 2, we have

$$\gamma(D(C))^* = \sigma_D(C) = (t_{D(C)})^* = \sigma_C \circ D^*.$$

Now, as by assumption $0 \in \text{ri} C$, we have $0 \in \text{ri}(C^\circ)$, and therefore $\text{Im}(D^*) \cap \text{ri}(C^\circ) \neq \emptyset$. 

28
By virtue of [20, Theorem X.2.2.3] and Lemma 2, we get
\[ \gamma_{D(C)}(x) = \sigma_{(D(C))^+}(x) = \sigma_{\pi_{C\circ D}(w) \leq 1}(x) = \left( \pi_{\sigma_C(w) \leq 1 \circ D^*} \right)^*(x) = \inf_{v \in \ker(D)} \sigma_{\sigma_C(w) \leq 1}(v) \quad \text{s.t.} \quad Dv = x \]
\[ = \inf_{z \in \ker(D)} \sigma_{\sigma_C(w) \leq 1}(D^+ x + z) \]
\[ = \inf_{z \in \ker(D)} \gamma_C(D^+ x + z). \]

\[ \square \]

**Proof of Proposition 1.**

(i) Each element of \( \bar{S}_x \) can be written as \( u = \sum_{i=1}^{k} \rho_i \eta_i \), for \( k > 0 \), where \( \eta_i \in \partial J(x) \) and \( \sum_{i=1}^{k} \rho_i = 1 \). By Fenchel identity applied to the gauge \( J \), and using Lemma 2(iii), we have
\[ \langle x, \eta_i \rangle = J(x) + \iota_{C^*}(\eta_i), \quad \forall i. \]
Since \( \eta_i \in \partial J(x) \subseteq C^\circ \), we get
\[ \langle x, \eta_i \rangle = J(x), \quad \forall i, \]
Multiplying by \( \rho_i \) and summing this identity over \( i \) and using the fact that \( \sum_{i=1}^{k} \rho_i = 1 \) we obtain the desired result.

(ii) This is due to the fact that \( e_x \) is the orthogonal projection of 0 on the affine space \( \bar{S}_x \). It is therefore an element of \( \bar{S}_x \cap (\bar{S}_x - e_x)^\perp \), i.e. \( e_x \in \bar{S}_x \cap T_x \).

(iii) This is straightforward from the fact that \( S_x = \{ \eta \in \mathbb{R}^N : \eta \tau_x = 0 \} \), \( \bar{S}_x = S_x + e_x \) and \( e_x \in T_x \) from (ii).

(iv) For any \( v \in S_x \), we have \( v + e_x \in \bar{S}_x \) since \( e_x \in \bar{S}_x \). Thus applying (i), we get \( \langle x, e_x + v \rangle = J(x) \) and \( \langle x, e_x \rangle = J(x) \). Combining both identities implies that \( \langle x, v \rangle = 0, \forall v \in S_x \), or equivalently that \( x \in S_x^\perp = T_x \).

\[ \square \]

**Proof of Proposition 2.** Let \( x \in \mathbb{R}^N \). We have
\[ \partial J(x) = F_{C^*}(x) = H \cap C^\circ, \]
where \( H = \{ \eta \in \mathbb{R}^N : \langle \eta, x \rangle = J(x) \} \) is the supporting hyperplane of \( C^\circ \) at \( x \). By Proposition 1(i), we have
\[ \bar{S}_x = \text{aff } \partial J(x) \subseteq H, \]
which implies that

\[ \overline{S}_x \cap C^\circ \subseteq H \cap C^\circ. \]

The converse inclusion is true since \( \partial J(x) = H \cap C^\circ \subseteq \overline{S}_x. \)

Proof of Proposition 3. The first assertion follows from Lemma 1(v) since \( 0 \in \text{ri}(\partial J(x) - f_x) \). Let’s now turn to the second part. Since \( f_x \in \text{ri} \partial J(x) \subseteq \overline{S}_x \), Proposition 1 implies that \( f_x = P_{S_x}(f_x) + P_{T_x}(f_x) = P_{S_x}(f_x) + e_x \). Hence, using Proposition 2, we get

\[
\partial J(x) - f_x = (C^\circ - f_x) \cap (\overline{S}_x - f_x) = (C^\circ - f_x) \cap (S_x - \{P_{S_x}(f_x)\}) = (C^\circ - f_x) \cap S_x.
\]

We therefore obtain

\[
J(\eta) = \gamma(C^\circ - f_x) \circ S_x(\eta) = \max(\gamma(C^\circ - f_x)(\eta), \gamma_S(\eta)) = \gamma(C^\circ - f_x(\eta) + \iota S_x(\eta)).
\]

At this stage, Lemma 3 does not apply straightforwardly since \( 0 \in C^\circ \) but \( f_x \neq 0 \) in general. However, proceeding as in the proof of that lemma, we arrive at

\[
\gamma(C^\circ + \{-f_x\})(\eta) = \sup_{\rho \in [0,1]} \rho J^\circ \vee (1 - \rho) \gamma_{\{-f_x\} \cup \{0\}}(\eta)
\]

where, from Definition 2, \( \{-f_x\}^\circ = \{\eta : \langle \eta, f_x \rangle \geq -1\} \), which indeed contains the origin as an interior point. Continuing from the last equality, we get

\[
\gamma(C^\circ + \{-f_x\})(\eta) = \sup_{\rho \in [0,1]} \rho J^\circ \vee (1 - \rho) \gamma_{\{-f_x\} \cup \{0\}}(\eta)
\]

It is easy to see that

\[
\gamma_{\{-f_x; \mu \in [0,1]\}}(\langle -\eta \rangle) = \begin{cases} 
\tau & \text{if } \eta \in \tau f_x, \tau \in \mathbb{R}_+, \\
+\infty & \text{otherwise}.
\end{cases}
\]

Thus

\[
\gamma(C^\circ + \{-f_x\})(\eta) = \inf_{\rho \in [0,1]} \sup_{\tau \geq 0} \rho J^\circ(\tau f_x + \eta) + (1 - \rho) \tau.
\]
Recalling that $J^\circ$ is a bounded gauge, hence continuous, the objective in the sup inf fulfills the assumption of the second assertion of Lemma 3, whence we get

$$\gamma_{C^\circ + \{-f\}}(\eta) = \inf_{\tau \geq 0} \max(J^\circ(\tau f_x + \eta), \tau).$$

Proof of Proposition 4. The gauge $J_{f_x}$ is the support function of the set

$$K_x \overset{\text{def.}}{=} \partial J_x - f_x = \{ \eta \in \mathbb{R}^N : J^\circ_{f_x}(\eta) \leq 1 \} \subset S_x,$$

where the inclusion follows from Proposition 3.

(i) Since $K_x$ is a bounded set, its support function is also bounded [20, Proposition V.2.1.3]. It follows that $\text{dom} \ J_{f_x} = \mathbb{R}^N$.

(ii) We have

$$J_{f_x}(d) = \sup_{\eta \in K_x} \langle \eta, d \rangle = \sup_{\eta \in K_x} \langle \eta, d \rangle_{\eta \in K_x} = \sup_{\eta \in K_x} \langle \eta, d_{S_x} \rangle + \langle \eta, d_{T_x} \rangle = \sup_{\eta \in K_x} \langle \eta, d_{S_x} \rangle$$

where we used the fact that $\langle \eta, d_{T_x} \rangle = 0$ on $K_x$.

(iii) As a consequence of (ii), $J_{f_x}(d_{T_x}) = 0$. Clearly, $T_x \subset \text{Ker}(J_{f_x})$ and $J_{f_x}$ is constant along all affine subspaces parallel to $T_x$. But, since $0 \in \text{ri} K_x$, excluding the origin, the supremum in $J_{f_x}$ is always attained at some nonzero $\eta \in K_x \subset S_x$. Thus $J_{f_x}(d) > 0$ for all $d$ such that $d \notin T_x$. This shows that actually $\text{Ker}(J_{f_x}) = T_x$. In particular, this yields that on $S_x$, the gauge $J_{f_x}$ is coercive.

(iv) Using some calculus rules with support functions and assertion (ii), we have

$$J_{f_x}(d) = J_{f_x}(d_{S_x}) = \sigma_{(C^\circ + \{-f\}) \cap S_x}(d_{S_x})$$

Proof of Theorem 1. We embark from

$$\partial J(x) = \{ \eta \in \mathbb{R}^N : \eta \in C^\circ \text{ and } \langle \eta, x \rangle = J(x) \}.$$
Invoking Proposition 1, we get that for every \( \eta \in \partial J(x) \), \( \eta_{T_x} = e_x \), and \( P_{T_x}(f_x) = e_x \). It remains now to uniquely characterize the part of the subdifferential lying in \( S_x \), i.e. \( \partial J(x) - e_x \). Since \( f_x \in \text{ri} \partial J(x) \), we have from the one-to-one correspondence of Lemma 1(i) and the definition of the antipromoting gauge,

\[
\eta \in \{ \eta \in \mathbb{R}^N : J(f_x)(\eta_{S_x} - P_{S_x}(f_x)) \leq 1 \} \iff \eta_{S_x} - P_{S_x}(f_x) \in \partial J(x) - f_x \iff \eta_{S_x} \in \partial J(x) - e_x \iff \eta \in \partial J(x).
\]

Proof of Proposition 5. This is a convenient rewriting of the fact that \( x \) is a global minimizer if, and only if, \( 0 \) is a subgradient of the objective function at \( x \).

(i) For problem \((P_\lambda(y))\), this is equivalent to

\[
\frac{1}{\lambda} \Phi^*(y - \Phi x) \in \partial J(x).
\]

Projecting this relation on \( T \) and \( S \) yields the desired result.

(ii) Let’s turn to problem \((P_0(y))\). We have at any global minimizer \( x \)

\[
0 \in \partial J(x) + \Phi^* N_{\{ \alpha : \alpha = y \}}(\Phi x)
\]

where \( N_{\{ \alpha : \alpha = y \}}(x) \) is the normal cone of the constraint set \( \{ \alpha : \alpha = y \} \) at \( x \), which is obviously the whole space \( \mathbb{R}^Q \). Thus, this monotone inclusion is equivalent to the existence of \( \alpha \in \mathbb{R}^Q \) such that

\[
\Phi^* \alpha \in \partial J(x).
\]

Projecting again this on \( T \) and \( S \) proves the assertion.

Proof of Lemma 5. Let \( J = \gamma_C, x \in T \) and \( x' \in S \).

32
By virtue of Lemma 2, we have

\[ J^\circ (x + x') = \sup_{u \in C} \langle x + x', u \rangle \]
\[ = \sup_{J(u) \leq 1} \langle x + x', u \rangle \]
\[ = \sup J(u_T + u_S) \leq \langle x, u_T \rangle + \langle x', u_S \rangle \]
\[ = \sup J(u_T) + J(u_S) \leq \langle x, u_T \rangle + \langle x', u_S \rangle \]
\[ = \sup_{\rho \in [0,1]} \sup_{J(u_T) \leq \rho, J(u_S) \leq 1 - \rho} \langle x, u_T \rangle + \langle x', u_S \rangle \]
\[ = \sup \rho \sup \langle x, u_T \rangle + (1 - \rho) \sup \langle x', u_S \rangle \]
\[ \leq \rho J(x_T) + (1 - \rho) J(x_S) \]
\[ = \max (\sigma_{C \cap T}(x), \sigma_{C \cap S}(x')) \].

Since

\[ \sigma_{C \cap T}(x) = \overline{\inf (\sigma_C(x), \iota_S(x)))} = \sigma_{C}(x) = J^\circ(x) \]

and

\[ \sigma_{C \cap S}(x') = \overline{\inf (\sigma_C(x'), \iota_T(x'))} = \sigma_{C}(x') = J^\circ(x') \],

the implication follows.

\[ \Rightarrow: \] Using again Lemma 2, we get

\[ J(x + x') = \sup_{u \in C} \langle x + x', u \rangle \]
\[ = \sup_{J(u_T + u_S) \leq 1} \langle x, u_T \rangle + \langle x', u_S \rangle \]
\[ = \max (J(u_T) + J(u_S)) \leq 1 \]
\[ = \sup_{\rho \in [0,1]} \sup_{v \in C \cap T} \langle x, v \rangle + \sup_{w \in C \cap S} \langle x', w \rangle \]
\[ = \sigma_{C \cap T}(x) + \sigma_{C \cap S}(x') \]
\[ = \overline{\inf (\sigma_{C}(x), \iota_S(x)))} + \overline{\inf (\sigma_{C}(x'), \iota_T(x'))} \]
\[ = \sigma_{C}(x) + \sigma_{C}(x') \]
\[ = J(x) + J(x') \].

This concludes the proof. \(\Box\)

**Proof of Proposition 6.** Let \( J = \gamma_C \). We only need to show that \( J^\circ_{e_x} (\eta_{S_x}) = J^\circ(\eta_{S_x}) \).
This follows from Proposition 3, Lemma 5 and Lemma 2(ii). Indeed,

\[ J^\circ(e_x + \eta S_x) = \inf_{\tau \geq 0} \max(\tau J^\circ(e_x), J^\circ(\eta S_x), \tau) \]

from Proposition 3,

\[ = \inf_{\tau \geq 0} \max(\tau J^\circ(e_x), J^\circ(\eta S_x), \tau) \]

from Lemma 5,

\[ = \inf_{\tau \geq 0} \max(\tau J^\circ(\eta S_x), \tau) \]

from \( e_x \in \partial J(x) \subset C^o \),

\[ = J^\circ(\eta S_x). \]

B. Proofs of Section 3

Proof of Lemma 6. Let \( x_1, x_2 \) be two (global) minimizers of \((P_\lambda(y))\). Suppose that \( \Phi x^1 \neq \Phi x^2 \). Define \( x_t = tx_1 + (1 - t)x_2 \) for any \( t \in (0, 1) \). By strict convexity of \( u \mapsto ||y - u||^2 \), one has

\[ \frac{1}{2} ||y - \Phi x_t||^2 < \frac{t}{2} ||y - \Phi x_1||^2 + \frac{1 - t}{2} ||y - \Phi x_2||^2. \]

Since \( J \) is convex, we get

\[ J(x_t) \leq tJ(x_1) + (1 - t)J(x_2). \]

Combining these two inequalities contradicts the fact that \( x_1, x_2 \) are global minimizers of \((P_\lambda(y))\).

Proof of Theorem 2. To prove this theorem, we need the following lemmata.

**Lemma 7.** Let \( C \) be a non-empty closed convex set and \( f \) a proper lsc convex function. Let \( x \) be a minimizer of \( \min_{z \in C} f(z) \). If

\[ f'(x, z - x) > 0 \quad \forall z \in C, z \neq x, \]

then, \( x \) is the unique solution of \( f \) on \( C \).

**Proof.** We first show that \( t \mapsto (f(x + t(z - x)) - f(z)) / t \) is non-decreasing on \((0, 1]\). Indeed, let \( g : [0, 1] \to \mathbb{R} \) a convex function such that \( g(0) = 0 \). Let \((t, s) \in (0, 1]^2 \) with \( s > t \). Then,

\[ g(t) = g(s(t/s)) = g(s(t/s) + (1 - t/s)0) \]

\[ \leq t \frac{g(s)}{s} + (1 - t/s)g(0) \]

\[ = t \frac{g(s)}{s}, \]
which proves that $t \in (0, 1] \mapsto \frac{g(t)}{t}$ is non-decreasing on $(0, 1]$. Since $f$ is convex, applying this result shows that the function

$$t \in (0, 1] \mapsto g(t) = f(x + t(z - x)) - f(z)$$

is such that $g(0) = 0$ and $g(t)/t$ is non-decreasing.

Assume now that $f'(x, z - x) > 0$. Then, for every $x \in C$,

$$g(1) = f(z) - f(x) \geq f'(x, z - x) > 0, \quad \forall z \in C, z \neq x,$$

which is equivalent to $x$ being the unique minimizer of $f$ on $C$.

We now compute the directional derivative of a bounded gauge $J$.

**Lemma 8.** The directional derivative $J'(x, \delta)$ at point $x \in \mathbb{R}^N$ in the direction $\delta$ reads

$$J'(x, \delta) = \langle e_x, \delta_T \rangle + \langle P_{S_x}(f_x), \delta_{S_x} \rangle + J_f(x, \delta).$$

**Proof.** This comes directly from the structure of $J_f$. Indeed, one has

$$J_f(x, \delta) = \sup_{\eta \in \partial J(\eta)} \langle \eta, \delta \rangle$$

Using Proposition 4(ii)

$$= -\langle \delta, f_x \rangle + \sup_{\eta \in \partial J(\eta)} \langle \eta, d \rangle$$

$$= -\langle \delta, f_x \rangle + J'(x, \delta)$$

$$= -\langle e_x, \delta_T \rangle - \langle P_{S_x}(f_x), \delta_{S_x} \rangle + J'(x, \delta).$$

We are now in position to show Theorem 3. We provide the proof for $(P_\lambda(y))$. That of $(P_0(y))$ is similar.

Let $x$ be a solution of $(P_\lambda(y))$. According to Lemma 6, the set of minimizers of $(P_\lambda(y))$ reads $\mathcal{M} \subseteq x + \text{Ker}(\Phi)$, which is a convex set. We can therefore rewrite $(P_\lambda(y))$ as

$$\min_{z \in \mathcal{M}} J(z).$$

Invoking Lemma 7 with $C = \mathcal{M}, x$ is thus the unique minimizer if

$$\forall \delta \in \text{Ker}(\Phi) \setminus \{0\}, \quad J'(x, \delta) > 0.$$ Using Lemma 8 and the fact that $\text{Ker}(\Phi)$ is a subspace, this is equivalent to

$$\forall \delta \in \text{Ker}(\Phi) \setminus \{0\}, \quad \langle e_x, \delta_T \rangle + \langle P_{S_x}(f_x), \delta_{S_x} \rangle < J_f(-\delta_S).$$

which is $(\text{NSP}^S)$. 

35
Proof of Corollary 1. Using [20, Theorem V.2.2.3], we know that
\[ \eta \in \ri(\partial J(x)) \iff J'(x, \delta) > \langle \eta, \delta \rangle \quad \forall \delta \text{ such that } J'(x, \delta) + J'(x, -\delta) > 0. \]

Applying this with \( \eta = \Phi^*\alpha \in \ri(\partial J(x)) \), and using Lemma 8, we obtain
\[ \Phi^*\alpha \in \ri(\partial J(x)) \iff J'(x, \delta) > \langle \alpha, \Phi \delta \rangle \quad \forall \delta \text{ such that } J'(x, \delta) + J'(x, -\delta) > 0. \]

Moreover, since \( J_f(x) \) and \( \Ker(J_f(x)) = T_x = T \) from Proposition 4(iii), and \( (C_T) \) holds, we get
\[ \Phi^*\alpha \in \ri(\partial J(x)) \iff J'(x, \delta) > \langle \alpha, \Phi \delta \rangle \forall \delta \not\in T \Rightarrow J'(x, \delta) > 0 \quad \forall \delta \in \Ker(\Phi). \]

We conclude using Theorem 2.

Proof of Theorem 3.

(i) Let the dual vector \( \alpha = (y - \Phi x)/\lambda \), and \( \eta = \Phi^*\alpha \in \partial J(x) \) by Theorem 1(i). We then observe that
\[ \eta \in \{ \eta \in \mathbb{R}^N : J_f^\circ(x) \mathcal{P}_S(x) - \mathcal{P}_S(f(x)) < 1 \} \iff \eta_S - \mathcal{P}_S(f(x)) \in \ri(\partial J(x) - \{f(x)\}) \iff \eta \in \ri(\partial J(x)). \]

Thus, applying Corollary 1 with such a dual vector yields the assertion.

(ii) The proof is similar to (i) except that we invoke Theorem 1(ii).

Proof of Proposition 7.

(i) First, we have
\[ \partial H(x) = \partial J(x) + \partial G(x). \]

Let \( S^J = \text{span}(\partial J(x) - \eta^J) \) and \( S^G = \text{span}(\partial G(x) - \eta^G) \), for any pair \( \eta^J \in \partial J(x) \) and \( \eta^G \in \partial G(x) \). Choosing \( \eta^H = \eta^J + \eta^G \in \partial H(x) \) we have
\[ S^H = \text{span}(\partial H(x) - \eta^H) = \text{span}((\partial J(x) - \eta^J) + (\partial G(x) - \eta^G)) = \text{span}(\text{span}(\partial J(x) - \eta^J) + \text{span}(\partial G(x) - \eta^G)) = \text{span}(S^J \cup S^G). \]

As a consequence we have \( T^H = (S^H)^\perp = T^J \cap T^G. \)
(ii) Moreover, since \( T^H \perp S^I \cup S^G \) we have from Proposition 1(iii) that
\[
e_{H} = P_{T^H} (\partial H(x)) = P_{T^H} (\partial J(x) + \partial G(x)) = P_{T^H} (e_J + P_{S^J} \partial J(x) + e_G + P_{S^G} \partial G(x)) = P_{T^H} (e_J + e_G).
\]

(iii) As \( f_x^J \in \text{ri} \partial J(x) \) and \( f_x^G \in \text{ri} \partial G(x) \), it follows from [33, Corollary 6.6.2] that \( f_x^H = f_x^J + f_x^G \in \text{ri} \partial J(x) + \text{ri} \partial G(x) = \text{ri} (\partial J(x) + \partial G(x)) = \text{ri} \partial H(x) \).

The antipromoting gauge associated to \( H \) is then
\[
H_f^\partial = \gamma(\partial H(x) - f_x^J) + (\partial G(x) - f_x^G),
\]
which is coercive and bounded on \( S^H \) according to Proposition 3. Invoking Lemma 3, we get the desired result since for any \( \rho \geq 0 \),
\[
u(u + (1 - \rho)G^2(x) - (\eta - u) = \rho \gamma(\partial J(x) - f_x^J) + (1 - \rho) \gamma(\partial J(x) - f_x^G)\]
is bounded and continuous on \( S^I \intercap (S^G + \eta) \), for \( \eta \in S^H = \text{span}(S^I + S^G) \) by (i).

\[\square\]

\textbf{Proof of Proposition 8.} In the following, all operator bounds that appear are finite owing to the coercivity assumption on the involved gauges in Definition 9 of a PRG.

It is straightforward to see that the function \( \Gamma^H = \max(\Gamma^J, \Gamma^G) \) is indeed a gauge, which is bounded and coercive on \( T^H = T^J \cap T^G \). Moreover, given that both \( J \) and \( G \) are PRG at \( x \) with corresponding parameters \( \nu^J_x \) and \( \nu^G_x \), we have with the advocated choice of \( \Gamma^H \) and \( \nu^H_x \),
\[
\Gamma^J(x - x') \leq \nu^J_x \quad \text{and} \quad \Gamma^G(x - x') \leq \nu^G_x,
\]
for every \( \forall x' \in T^H_x \) such that \( \Gamma^H(x - x') \leq \nu^H_x \). It follows that:

\begin{itemize}
  \item Since \( J \) and \( G \) are both PRG, then we have \( T^J_x = T^J_{x'} \) and \( T^G_x = T^G_{x'} \), and thus by Proposition 7(i)
    \[
    T^H_x = T^J_x \cap T^G_x = T^J_{x'} \cap T^G_{x'} = T^H_{x'} = T^H.
    \]
  \item \( \mu^H_x \)-\textbf{stability:} we have from Proposition 7(ii)
    \[
    \Gamma^H(e_x^H - e_x^H) = \Gamma^H (P_{T^H} (e_x^J + e_x^G - e_x^J - e_x^G)) \\
    \leq \Gamma^H(P_{T^H} (e_x^J - e_x^J)) + \Gamma^H (P_{T^H} (e_x^G - e_x^G)) \\
    \leq \mathcal{M}_{T^H, T^H} (P_{T^H}) \Gamma^J (e_x^J - e_x^J) + \mathcal{M}_{T^G, T^H} (P_{T^H}) \Gamma^G (e_x^G - e_x^G) \\
    \leq (\mu^J_x \mathcal{M}_{T^H, T^H} (P_{T^H}) + \mu^G_x \mathcal{M}_{T^G, T^H} (P_{T^H})) \Gamma^H(x - x'),
    \]
    where we used \( \mu^J_x \) and \( \mu^G_x \)-stability of \( J \) and \( G \) in the last inequality.
\end{itemize}
• $e^H_x$-stability: the fact that $S^J \subseteq S^H$ and $S^G \subseteq S^H$ and subadditivity of gauges lead to

$$H^g_{f^H} (P_{S^G} (f^H_x - f^G_x))$$

$$= H^g_{f^H} (P_{S^J} (f^J_x - f^G_x)) + P_{S^G} (f^G_x - f^G_x) + P_{S^H} (e_x^J - e_x^G) + P_{S^H} (e_x^G - e_x^G)$$

$$\leq H^g_{f^H} (P_{S^J} (f^J_x - f^G_x)) + H^g_{f^H} (P_{S^G} (f^G_x - f^G_x))$$

$$+ H^g_{f^H} (P_{S^H} (e_x^J - e_x^G)) + H^g_{f^H} (P_{S^H} (e_x^G - e_x^G)) .$$

According to Proposition 7(iii), we have

$$H^g_{f^H} (P_{S^J} (f^J_x - f^J_x)) = \inf_{\eta_1 + \eta_2 \in P_{S^H} (f^J_x - f^J_x)} \max(J^g_{f^H} (\eta_1), G^g_{f^H} (\eta_2)) .$$

Since $\text{dom} J^g_{f^H} = S^J$, $(\eta_1, \eta_2) = (P_{S^J} (f^J_x - f^J_x), 0)$ is a feasible point of the last problem, and we get

$$H^g_{f^H} (P_{S^J} (f^J_x - f^J_x)) \leq J^g_{f^H} (P_{S^J} (f^J_x - f^J_x)) .$$

Moreover, as $e_x^J, e_x^G, \in T^J$ (see Proposition 1(ii)) and $S^J \subseteq S^H$, we have

$$\min_{\eta_1 \in T^J \cap T^{S^H}, \eta_2 \in S^H} \|\eta_1 + \eta_2 - (e_x^J - e_x^G)\|^2$$

$$= \min_{\eta_1 \in T^J \cap T^{S^H}, \eta_2 \in S^H} \|\eta_1 - (e_x^J - e_x^G)\|^2 + \|\eta_2\|^2$$

$$= \min_{\eta_1 \in T^J \cap T^{S^H}, \eta_2 \in S^H} \|\eta_1 - (e_x^J - e_x^G)\|^2 + \|\eta_2\|^2$$

$$= \min_{\eta_1 \in S^H \cap T^J} \|\eta_1 - (e_x^J - e_x^G)\|^2 .$$

That is

$$P_{S^H} (e_x^J - e_x^G) = P_{S^H \cap T^J} (e_x^J - e_x^G) .$$

Thus

$$H^g_{f^H} (P_{S^H} (e_x^J - e_x^G)) \leq \mathcal{M}_{T^J \cap T^G} (P_{S^H \cap T^J} (e_x^J - e_x^G)) .$$

Similar reasoning leads to the following bounds

$$H^g_{f^H} (P_{S^G} (f^G_x - f^G_x)) \leq G^g_{f^H} (P_{S^G} (f^G_x - f^G_x)) ,$$

$$H^g_{f^H} (P_{S^H} (e_x^G - e_x^G)) \leq \mathcal{M}_{T^J \cap T^G} (P_{S^H \cap T^G} (e_x^G - e_x^G)) .$$
Having this, we can continue to bound (9) as

\[
H^\phi_{J^\phi} (P_{\mathcal{S}^u}(f^H_x - f^H_{x'})) \\
\leq J^\phi_{J^\phi} (P_{\mathcal{S}^u}(f^H_x - f^H_{x'})) + G^\phi_{\mathcal{S}^u}(f^H_x - f^H_{x'}) \\
+ \mathcal{M}_{\Gamma^J, H^\phi} (P_{\mathcal{S}^u \cap \mathcal{T}^J}) \Gamma^J (\epsilon^J_x - \epsilon^J_{x'}) + \mathcal{M}_{\Gamma^J, H^\phi} (P_{\mathcal{S}^u \cap \mathcal{T}^J}) \Gamma^G (\epsilon^G_x - \epsilon^G_{x'}) \\
\leq \tau^J_x \Gamma^J (x - x') + \tau^G_x \Gamma^G (x - x') + \mu^J_x \mathcal{M}_{\Gamma^J, H^\phi} (P_{\mathcal{S}^u \cap \mathcal{T}^J}) \Gamma^J (x - x') \\
+ \mu^G_x \mathcal{M}_{\Gamma^G, H^\phi} (P_{\mathcal{S}^u \cap \mathcal{T}^J}) \Gamma^G (x - x') \\
\leq \left( \tau^J_x + \tau^G_x + \mu^J_x \mathcal{M}_{\Gamma^J, H^\phi} (P_{\mathcal{S}^u \cap \mathcal{T}^J}) + \mu^G_x \mathcal{M}_{\Gamma^G, H^\phi} (P_{\mathcal{S}^u \cap \mathcal{T}^J}) \right) \Gamma^H (x - x') ,
\]

where the last two inequalities \(J\) and \(G\) follow from \(\mu^J_x, \tau^J_x, \mu^G_x\) and \(\tau^G_x\)-stability of \(J\) and \(G\).

- **\(\xi^H_x\)-stability:** Proposition 7(iii) again yields that for any \(\eta \in S^H\)

\[
H^\phi_{J^\phi} (\eta) = \inf_{\eta_1 + \eta_2 = \eta} \max(J^\phi_{J^\phi} (\eta_1), G^\phi_{J^\phi} (\eta_2)) \\
\leq \max(J^\phi_{J^\phi} (\eta_1), G^\phi_{J^\phi} (\eta_2))
\]

for any feasible \((\eta_1, \eta_2) \in S^J \times S^G \cap \{(\eta_1, \eta_2) : \eta_1 + \eta_2 = \eta\} \). Now both \(J\) and \(G\) are PRG, hence respectively \(\xi^J_x\)- and \(\xi^G_x\)-stable. Therefore, with the form of \(\Gamma^H\) we have

\[
J^\phi_{J^\phi} (\eta_1) \leq (1 + \xi^J_x \Gamma^J (x - x')) J^\phi_{J^\phi} (\eta_1) \leq \beta J^\phi_{J^\phi} (\eta_1) \\
G^\phi_{J^\phi} (\eta_2) \leq (1 + \xi^G_x \Gamma^G (x - x')) G^\phi_{J^\phi} (\eta_2) \leq \beta G^\phi_{J^\phi} (\eta_2) ,
\]

where \(\beta = 1 + \max (\xi^J_x, \xi^G_x) \Gamma^H (x - x')\). Whence we get

\[
\max(J^\phi_{J^\phi} (\eta_1), G^\phi_{J^\phi} (\eta_2)) \leq \beta \max(J^\phi_{J^\phi} (\eta_1), G^\phi_{J^\phi} (\eta_2)) .
\]

Taking in particular

\[
(\eta_1, \eta_2) \in \text{Argmin}_{\eta_1 + \eta_2 = \eta} \max(J^\phi_{J^\phi} (\eta_1), G^\phi_{J^\phi} (\eta_2))
\]

we arrive at

\[
H^\phi_{J^\phi} (\eta) \leq \beta \inf_{\eta_1 + \eta_2 = \eta} \max(J^\phi_{J^\phi} (\eta_1), G^\phi_{J^\phi} (\eta_2)) = \beta H^\phi_{J^\phi} (\eta) .
\]

This completes the proof. \(\square\)

**Proof of Proposition 9.**
(i) One has $\partial J = D \circ \partial J_0 \circ D^*$, hence $S = DS_0 = \operatorname{Im}(DS_0)$ and $T = S^\perp = \operatorname{Ker}(D_{S_0}^*)$.

(ii) As $S = DS_0 = Dc_0 + S$, we get from Proposition 1

$$
e \in \arg\min_{z \in S} \|z\| = \arg\min_{z \in S} \|z\| = Dc_0 + \arg\min_{h \in S} \|h + Dc_0\|
= Dc_0 + P_S(-Dc_0) = (\operatorname{Id} - P_S)Dc_0 = P_T Dc_0 .$$

(iii) With such a choice of $f_x$, we have

$$f_0, D^* x \in \text{ri} \partial J_0(D^* x) \Rightarrow Df_0, D^* x \in \text{ri} \partial J_0(D^* x)$$
\[\iff\]
\[f_x \in \text{ri} D\partial J_0(D^* x) \iff f_x \in \text{ri} \partial J(x) .\]

We follow the same lines as in the proof of Lemma 4, where we additionally invoke Proposition 4(ii) to get

$$J_{f_0}(d) = 1 \cdot \sigma \partial J_{f_0, D^* x} \eta_1(\eta)
= \sigma \partial J_{f_0, D^* x} \eta_1(\eta)
= \left( J_{f_0, D^* x} \nu \right)^* \eta_1(\eta)
= \inf_{z \in \operatorname{Ker}(D_{S_0})} \left( J_{f_0, D^* x} \nu \right)^* \eta_1(\eta) .$$

The infimum is bounded and is attained necessarily at some $z \in \operatorname{Ker}(D_{S_0}) \cap S_0 \neq \emptyset$ since $\operatorname{dom} J_{f_0, D^* x} = S_0$ and $\operatorname{Im}(D_{S_0}^*) = \operatorname{Im}(D_{S_0}^*) \subset S_0$. Moreover, $\operatorname{Ker}(D_{S_0}) \cap S_0 = \operatorname{Ker}(D) \cap S_0$.

\[\square\]

**Proof of Proposition 10.** In the following, all operator bounds that appear are finite owing to the coercivity assumption on the involved gauges in Definition 9 of a PRG.

- Let $x'$ such that

$$\Gamma(x - x') \leq \frac{1}{M_{\Gamma, \nu_0}(D^*)} \nu_{0, D^* x} .$$
• $\tau_s$-stability: we now have
\[
\Gamma(e_x - e'_x) = \Gamma(P_T D(e_0, D^* x) - e_0, D^* x'))
\leq \mu_0, D^* x - e_0, D^* x')
\leq \mu_0, D^* x, T_0(D^* x)\Gamma(0(D^* x - D^* x'))
\quad \text{using $\mu_0, D^* x$-stability of $J_0$}
\leq \mu_0, D^* x, T_0(D^* D^* x)\Gamma(0(D^* x - D^* x')).
\]

Thus, subadditivity yields
\[
J^2_{f_x}(P_S D P_S D_0 D^* x - D_0 D^* x'))
\leq J^2_{f_x}(P_S D P_S D_0 D^* x - D_0 D^* x')) + J^2_{f_x}(P_S D(e_0, D^* x - e_0, D^* x')).
\]

Using Proposition 9(iii) and $\tau_0, D^* x$-stability of $J_0$, we get the following bound on the first term
\[
J^2_{f_x}(P_S D P_S D_0 D^* x - D_0 D^* x'))
= \inf_{z \in \text{Ker}(D)}\{J^2_{f_x}(D^+_S P_S D P_S D_0 D^* x - D_0 D^* x') + z\}
\leq J^2_{f_x}(P_S D P_S D_0 D^* x - D_0 D^* x')) + J^2_{f_x}(P_S D(e_0, D^* x - e_0, D^* x')).
\]

Now, combining Proposition 9(iii) and $\mu_0, D^* x$-stability of $J_0$, we obtain the following bound on the second term
\[
J^2_{f_x}(P_S D(e_0, D^* x - e_0, D^* x'))
\leq \mu_0, D^* x, T_0(D^+_S P_S D(e_0, D^* x - e_0, D^* x'))
\leq \mu_0, D^* x, T_0(D^+_S P_S D)\Gamma(0(D^* x - D^* x')).
\]

Combining these inequalities, we arrive at
\[
J^2_{f_x}(P_S f_x - f'_x')) \leq \left(\tau_0, D^* x, T_0(D^+_S P_S D)
+ \mu_0, D^* x, T_0(D^+_S P_S D)\right)\Gamma(0(D^* x - D^* x')).
\]
whence we get $\tau_s$-stability.
\* \textbf{\(\xi_x\)-stability:} from Proposition 9(iii), we can write for any \(\eta \in S\)
\[
J^2_{f_x}(\eta) = \inf_{z \in \text{Ker}(D) \cap S_0} J^2_{f_{0,D^*x}}(D^+_S \eta + z)
\leq J^2_{f_{0,D^*x}}(D^+_S \eta + \bar{z})
\]
for any \(\bar{z} \in \text{Ker}(D) \cap S_0\).
Owing to \(\xi_{0,D^*x}\)-stability of \(J_0\), and since \(D^+_S \eta \in S_0\), we have for any feasible \(\bar{z} \in \text{Ker}(D) \cap S_0\)
\[
J^2_{f_{0,D^*x}}(D^+_S \eta + \bar{z}) \leq (1 + \xi_{0,D^*x} \Gamma_0(D^* \eta - D^* \eta')) J^2_{f_{0,D^*x}}(D^+_S \eta + \bar{z}).
\]
Taking in particular
\[
\bar{z} \in \text{Arginf}_{z \in \text{Ker}(D) \cap S_0} J^2_{f_{0,D^*x}}(D^+_S \eta + z)
\]
we get the bound
\[
J^2_{f_x}(\eta) \leq (1 + \xi_{0,D^*x} \Gamma_0(D^* \eta - D^* \eta')) \inf_{z \in \text{Ker}(D) \cap S_0} J^2_{f_{0,D^*x}}(D^+_S \eta + z)
\]
\[
= (1 + \xi_{0,D^*x} \Gamma_0(D^* \eta - D^* \eta')) J^2_{f_x}(\eta)
\]
\[
= (1 + \xi_{0,D^*x} \M_{\Gamma,\Gamma_0}(D^*)\Gamma(x - x')) J^2_{f_x}(\eta),
\]
where we used again Proposition 9(iii) in the first equality.

\(\square\)

**D. Proofs of Section 5**

\textbf{Proof of Theorem 4.} This is a straightforward consequence of Theorem 3(ii) by constructing an appropriate dual certificate from \(\text{IC}(x_0)\). Denote \(e = e_{x_0}, f = f_{x_0}\) and \(S = T^\perp\). Taking the dual vector \(\alpha = \Phi^+_T e\), we have on the one hand
\[
\Phi^+_T \Phi^+_T e = e
\]
since \(e \in \text{Im}(\Phi^+_T)\).
On the other hand,
\[
J^2_{f}(\Phi^+_T \Phi^+_T e - P_S f) = \text{IC}(x_0) < 1.
\]

\(\square\)

\textbf{Proof of Theorem 5.} To lighten the notation, we let \(\varepsilon = \|w\|, \nu = \nu_{x_0}, \mu = \mu_{x_0}, \tau = \tau_{x_0}, \xi = \xi_{x_0}, f = f_{x_0}\).

42
The strategy is to construct a vector which is the unique solution to
\[
\min_{x \in T} \frac{1}{2} \|y - \Phi x\|^2 + \lambda J(x), \quad (P^T_{\lambda}(y))
\]
and then to show that it is actually the unique solution to \((P_\lambda(y))\) under the assumptions of Theorem 5.

The following lemma gives a convenient implicit equation satisfied by the unique solution to \((P^T_{\lambda}(y))\).

**Lemma 9.** Let \(x_0 \in \mathbb{R}^N\) and denote \(T = T_{x_0}\). Assume that \((C_T)\) holds. Then \((P^T_{\lambda}(y))\) has exactly one minimizer \(\hat{x}\), and the latter satisfies
\[
\hat{x} = x_0 + \Phi^*_T w - \lambda (\Phi^*_T \Phi_T)^{-1} \hat{e} \quad \text{where} \quad \hat{e} \in P_T(\partial J(\hat{x})). \tag{10}
\]

**Proof.** Assumption \((C_T)\) implies that the objective in \((P^T_{\lambda}(y))\) is strongly convex on the feasible set \(T\), whence uniqueness follows immediately. By a trivial change of variable, \((P^T_{\lambda}(y))\) be also rewritten in the unconstrained form
\[
\hat{x} = \arg\min_{x \in \mathbb{R}^N} \frac{1}{2} \|y - \Phi_T x\|^2 + \lambda J(\Phi_T x).
\]
Thus, using Proposition 5(i), \(\hat{x}\) has to satisfy
\[
\Phi^*_T (y - \Phi_T \hat{x}) + \lambda \hat{e} = 0,
\]
for any \(\hat{e} \in P_T(\partial J(\hat{x}))\). Owing to the invertibility of \(\Phi\) on \(T\), i.e. \((C_T)\), we obtain (10).

We are now in position to prove Theorem 5. This is be achieved in three steps:

**Step 1:** We show that in fact \(T_{\hat{x}} = T\).

**Step 2:** Then, we prove that \(\hat{x}\) is the unique solution of \((P_\lambda(y))\) using Theorem 3.

**Step 3:** We finally exhibit an appropriate regime on \(\lambda\) and \(\varepsilon\) for the above two statements to hold.

**Step 1: Subspace equality.** By construction of \(\hat{x}\) in \((P^T_{\lambda}(y))\), it is clear that \(T_{\hat{x}} \subseteq T\).

The key argument now is to use that \(J\) is PRG at \(x_0\), and to show that
\[
\Gamma(x_0 - \hat{x}) \leq \nu, \tag{11}
\]
which in turn will imply subspace equality, i.e. \(T_{\hat{x}} = T\) (see Definition 9).

We have from (10) and subadditivity that
\[
\Gamma(x_0 - \hat{x}) \leq \Gamma(-\Phi^*_T w) + \lambda \Gamma((\Phi^*_T \Phi_T)^{-1} \hat{e})
\]
\[
\leq M_{T, \Gamma}((\Phi^*_T \Phi_T)^{-1}) \{\Gamma(-\Phi^*_T w) + \lambda \Gamma(\hat{e})\}
\]
\[
\leq M_{T, \Gamma}((\Phi^*_T \Phi_T)^{-1}) \{M_{T, \Gamma}(\Phi^*_T) \varepsilon + \alpha_0 \lambda\}. \tag{12}
\]
where $\alpha_0 = \Gamma(\hat{c})$. Consequently, to show that (11) is verified, it is sufficient to prove that
\[ A \varepsilon + B \lambda \leq \nu, \]  
where we set the positive constants
\[ A = \mathcal{M}_{\Gamma, \Gamma}((\Phi_T^* \Phi_T)^{-1}), \]
\[ B = \alpha_0 \mathcal{M}_{\Gamma, \Gamma}((\Phi_T^* \Phi_T)^{-1}). \]

Suppose for now that (C1) holds and consequently, $T = T$. Then decomposability of $J$ on $T$ (Theorem 1) implies that
\[ \hat{c} = P_T(\partial J(\hat{x})) = P_T(\partial J(\hat{x})) = \hat{c}, \]
where we have denote $\hat{c} = e_\hat{z}$. Thus (10) yields the following implicit equation
\[ \hat{x} = x_0 + \Phi_T^* w - \lambda(\Phi_T^* \Phi_T)^{-1} \hat{c}. \]  
(13)

**Step 2: $\hat{x}$ is the unique solution of (P$_\lambda(y)$).** Recall that under condition (C1), $J$ is decomposable at $\hat{x}$ and $x_0$ with the same model subspace $T$. Moreover, (13) is nothing but condition (2) in Theorem 3 satisfied by $\hat{x}$. To deduce that $\hat{x}$ is the unique solution of (P$_\lambda(y)$), it remains to show that (3) holds i.e.,
\[ J_f^\eta(\lambda^{-1} \Phi_T^* (y - \Phi \hat{x}) - \hat{f}_S) < 1. \]  
(14)

where we use the shorthand notations $\hat{f} = f_\hat{z}$ and $\hat{f}_S = P_S \hat{f}$.

Under condition (C1), the $\xi$-stability property (6) of $J$ at $x_0$ yields
\[ J_f^\eta(\lambda^{-1} \Phi_T^* (y - \Phi \hat{x}) - \hat{f}_S) \leq (1 + \xi (x_0 - \hat{x})) J_f^\eta(\lambda^{-1} \Phi_T^* (y - \Phi \hat{x}) - \hat{f}_S). \]  
(15)

Furthermore, from (13), we can derive
\[ \lambda^{-1} \Phi_T^* (y - \Phi \hat{x}) - \hat{f}_S = \Phi_T^* \Phi_T^* e + \lambda^{-1} \Phi_T^* Q_T w - \hat{f}_S, \]  
(16)

where $Q_T = \text{Id} - \Phi_T \Phi_T^* = P_{\text{Ker}(\Phi_T^*)}$. Inserting (16) in (15), we obtain
\[ J_f^\eta(\lambda^{-1} \Phi_T^* (y - \Phi \hat{x}) - \hat{f}_S) \leq (1 + \xi (x_0 - \hat{x})) J_f^\eta(\Phi_T^* \Phi_T^* e + \lambda^{-1} \Phi_T^* Q_T w - \hat{f}_S). \]

Moreover, subadditivity yields
\[ J_f^\eta(\Phi_T^* \Phi_T^* e + \lambda^{-1} \Phi_T^* Q_T w - \hat{f}_S) \leq J_f^\eta(\Phi_T^* \Phi_T^* e - f_S) + J_f^\eta(\Phi_T^* \Phi_T^* (\hat{e} - e)) + J_f^\eta(P_S(f - \hat{f})) + J_f^\eta(\lambda^{-1} \Phi_T^* Q_T w). \]  
(17)

We now bound each term of (17). In the first term, one recognizes
\[ J_f^\eta(\Phi_T^* \Phi_T^* e - f_S) \leq IC(x_0). \]  
(18)
Appealing to the $\mu$-stability property, we get
\begin{align}
J^*_f(\Phi^* S \Phi^+ (\hat{e} - e)) & \leq \mathcal{M}_{\Gamma, f}(\Phi^* S \Phi^+)^\Gamma(x_0 - \hat{x}). \\
J^*_f(\Phi^* S \Phi^+ (\hat{e} - e)) & \leq \mu \mathcal{M}_{\Gamma, f}(\Phi^* S \Phi^+)^\Gamma(x_0 - \hat{x}). 
\end{align}
(19)

From $\tau$-stability, we have
\begin{equation}
J^*_f(fS - \hat{f}S) \leq \tau \Gamma(x_0 - \hat{x}).
\end{equation}
(20)

Finally, we use a simple operator bound to get
\begin{equation}
J^*_f(\lambda \Phi^* S \Phi^+ Q T w) \leq 1 - \lambda M_{\Gamma, f} \Phi^* S \Phi^+ \epsilon.
\end{equation}
(21)

Following the same steps as for the bound (12), except using $\tilde{e} = \hat{e}$ here, gives
\begin{equation}
\Gamma(x_0 - \hat{x}) \leq \mathcal{M}_{\Gamma, f}(\Phi^* S \Phi^+)^{-1} \{ \mathcal{M}_{\Gamma, f}(\Phi^* S \Phi^+)^{-1} + \lambda \Gamma(\hat{e}) \}.
\end{equation}
(22)

Plugging inequalities (18)-(22) into (15) we get the upper-bound
\begin{align}
J^*_f(\Phi^* S \Phi^+ (\hat{e} - e)) & \leq M_{\Gamma, f}(\Phi^* S \Phi^+)^\Gamma(x_0 - \hat{x}) \\
J^*_f(\Phi^* S \Phi^+ (\hat{e} - e)) & \leq \tau \Gamma(x_0 - \hat{x}). \\
\end{align}
(23)

for (3) in Theorem 3 to be in force.

In particular, if $C \epsilon \leq \lambda$ holds for some constant $C > 0$ to be fixed later, then inequality (23) is true if
\begin{align}
P(\lambda) = a \lambda^2 + b \lambda + c > 0 \quad \text{where} \quad \\
a = -\xi \bar{\mu} (c_1/C + c_2)^2 \\
b = -(c_1/C + c_2) (\xi IC(x_0) + c_4/C + \bar{\mu}) \\
c = 1 - IC(x_0) - c_4/C.
\end{align}
(24)
Let us set the value of \( C \) to
\[
C = \frac{2c_4}{1 - \text{IC}(x_0)},
\]
which, for \( 0 \leq \text{IC}(x_0) < 1 \), it ensures that \( c = \frac{1 - \text{IC}(x_0)}{2} \) is bounded and positive, and thus, the polynomial \( P \) has a negative and a positive root \( \lambda_{\text{max}} \) equal to
\[
\lambda_{\text{max}} = \frac{b}{2a} \varphi \left( -\frac{ac}{b^2} \right),
\]
\[
\varphi(\beta) = \sqrt{1 + \beta} - 1, \quad \text{and} \quad H(\beta) = \frac{\beta + 1/2}{\beta(c_1/c_4 + 2c_2)} \varphi \left( \frac{2\beta}{(\beta + 1)^2} \right).
\]

To get the above lower-bound on \( \lambda_{\text{max}} \), we used that \( \varphi \) is increasing (in fact strictly) and concave on \( \mathbb{R}_+ \) with \( \varphi(1) = 0 \), and that \( \text{IC}(x_0) \in [0, 1] \). Consequently, we can conclude that the bounds
\[
\frac{2c_4}{1 - \text{IC}(x_0)} \epsilon \leq \lambda \leq \min \left( C_0 \nu, \frac{1 - \text{IC}(x_0)}{\xi} H(\bar{\mu}/\xi) \right)
\]
imply condition (23), which in turn yields (14).

**Step 3:** \( (C_1) \) and \( (C_2) \) are in agreement. It remains now that show the compatibility of \( (C_1) \) and \( (C_2) \), i.e., to provide appropriate regimes of \( \lambda \) and \( \epsilon \) such that both conditions hold simultaneously. We first observe that \( (C_1) \) and the left-hand-side of \( (C_2) \) both hold for \( \lambda \) fulfilling
\[
\lambda \leq C_0 \nu \quad \text{where} \quad C_0 = \left( \frac{A}{2c_4} + B \right)^{-1} \leq \left( \frac{1 - \text{IC}(x_0)}{2c_4} A + B \right)^{-1}.
\]
This updates \( (C_2) \) to the following ultimate range on \( \lambda \)
\[
\frac{2c_4}{1 - \text{IC}(x_0)} \epsilon \leq \lambda \leq \min \left( C_0 \nu, \frac{1 - \text{IC}(x_0)}{\xi} H(\bar{\mu}/\xi) \right).
\]

Now in order to have an admissible non-empty range for \( \lambda \), the noise level \( \epsilon \) must be upper-bounded as
\[
\epsilon \leq \frac{1 - \text{IC}(x_0)}{2c_4} \min \left( C_0 \nu, \frac{1 - \text{IC}(x_0)}{\xi} H(\bar{\mu}/\xi) \right).
\]
Finally, the constants provided in the statement of the theorem (and subsequent discussion) are as follows

\[ A_T = 2c_1, \quad B_T = C_0, \quad D_T = c_3, \quad \text{and} \quad E_T = c_1/c_4 + 2c_2, \]

which completes the proof. 

\[ \square \]

E. Proofs of Section 6

Proof of Proposition 11. The subdifferential of \( \| \cdot \|_1 \) reads

\[ \partial \| \cdot \|_1(x) = \{ \eta \in \mathbb{R}^N : \eta(I) = \text{sign}(x(I)) \quad \text{and} \quad \|\eta(I')\|_\infty \leq 1 \}. \]

The expressions of \( S_x, T_x, e_x \) and \( f_x \) follow immediately. Since \( e_x \in \text{ri} \partial \| \cdot \|_1(x) \) and \( \| \cdot \|_1 \) is separable, it follows from Definition 8 that the \( \ell^1 \)-norm is a strong gauge. Therefore \( J^\odot_{f_x} = J^\circ = \| \cdot \|_\infty \), and Proposition 6 specializes to the stated subdifferential.

Turning to piecewise regularity, let \( x' \in T \), i.e. \( I(x') \subseteq I(x) \), and assume that

\[ |x - x'|_\infty \leq \nu_x = (1 - \delta) \min_{i \in I} |x_i|, \quad \delta \in [0, 1]. \]

This implies that \( \forall i \in I(x), |x'_i| > \nu_x - |x - x'|_\infty \geq 0 \), which in turn yields \( I(x') = I(x) \), and thus \( T_{x'} = T_x \). Since the sign is also locally constant on the restriction to \( T \) of the \( \ell^\infty \)-ball centered at \( x \) of radius \( \nu_x \), one can choose \( \mu_x = 0 \). Finally \( \tau_x = \xi_x = 0 \) because \( f_x = e_x \).

Proof of Proposition 13. The proof of the first part was given Section 2.2 and Section 2.3 where the \( \ell^\infty \)-norm example was considered.

It remains to show piecewise regularity. Let \( x' \in T \), and assume that

\[ |x - x'|_1 \leq \nu_x = (1 - \delta) \min_{j \notin I} |x_j|, \quad \delta \in [0, 1]. \]

This means that \( x' \) lies in the relative interior of the \( \ell^1 \)-ball (relatively to \( T \)) centered at \( x \) of radius \( |x|_\infty - \max_{j \notin I} |x_j| \). Within this ball, the support and the sign pattern restricted to the support are locally constant, i.e. \( I(x) = I(x') \) and \( \text{sign}(x(I(x))) = \text{sign}(x'(I(x'))) \). Thus \( T_{x'} = T_x = T \) and \( e_{x'} = e_x \), and from the latter we deduce that \( \mu_x = 0 \). As \( f_x = e_x \) we also conclude that \( \tau_x = \xi_x = 0 \), which completes the proof.

Proof of Proposition 14. Again, the proof of the first part was given Section 2.2 and Section 2.4 where the \( \ell^1 - \ell^2 \)-norm example was handled.

Let \( x' \in T \), i.e. \( I(x') \subseteq I(x) \), and \( \nu_x = (1 - \delta) \min_{b \in I} |x_b|, \quad \delta \in [0, 1] \). First, observe that the condition

\[ |x - x'|_{\infty,2} = \max_{b \in B} |x_b - x'_b| \leq \nu_x \]
ensures that for all \( b \in I \)
\[
\|x'_b\| \geq \|x_b\| - |x_b' - x_b'| > \nu_x - |x - x'|_{\infty,2} \geq 0,
\]
and thus \( I(x') = I(x) \), i.e. \( T_{x'} = T_x \). Moreover, since the gauge is strong, one has \( \tau_x = \xi_x = 0 \). To establish the \( \mu_x \)-stability we use the following lemma.

**Lemma 10.** Given any pair of non-zero vectors \( u \) and \( v \) where, \( \|u - v\| \leq \rho \|u\| \), for \( 0 < \rho < 1 \), we have
\[
\left\| \frac{u}{\|u\|} - \frac{v}{\|v\|} \right\| \leq C_\rho \left( \frac{\|u - v\|}{\|u\|} \right),
\]
where \( C_\rho = \frac{\sqrt{2}}{\rho} \sqrt{1 - \sqrt{1 - \rho^2}} \in [1, \sqrt{2}] \).

**Proof.** Let \( d = v - u \) and \( \beta = \frac{(u, d)}{\|u\|\|d\|} \in [-1, 1] \). We then have the following identities
\[
\left\| \frac{u}{\|u\|} - \frac{v}{\|v\|} \right\|^2 = 2 - 2\left\langle \frac{u}{\|u\|}, \frac{v}{\|v\|} \right\rangle = 2 - 2\frac{\|u\|^2 + \|u\|\|d\|\beta}{\|u\|\|u\|^2 + \|d\|^2 + 2\|u\|\|d\|\beta},
\]
for non-zero vectors \( u \) and \( d \), the unique maximizer of (25) is \( \beta^* = -\|d\|/\|u\| \). Note that the assumption \( |d|/\|u\| \leq \rho < 1 \) assures \( \beta^* \) to comply with the admissible range of \( \beta \) and further, the argument of the square root will be always positive. Now, inserting \( \beta^* \) in (25), using concavity of \( \sqrt{d} \) on \( \mathbb{R}_+ \), and that \( |d|/\|u\| \leq \rho \), we can deduce the following bound
\[
\left\| \frac{u}{\|u\|} - \frac{v}{\|v\|} \right\|^2 \leq 2 - 2\sqrt{1 - \frac{|d|^2}{\|u\|^2}} = 2 - 2\left(1 - \frac{|d|^2}{\|u\|^2}\right) + \frac{|d|^2}{\|u\|^2}(1 - \rho^2)
\]
\[
\leq 2 - 2\left(1 - \frac{|d|^2}{\|u\|^2}\right) + \frac{|d|^2}{\|u\|^2}\sqrt{1 - \rho^2}
\]
\[
= 2 - 2\left(1 - 1 - \frac{1 - \sqrt{1 - \rho^2}}{\rho^2}\frac{|d|^2}{\|u\|^2}\right)
\]
\[
= 2\frac{1 - \sqrt{1 - \rho^2}}{\rho^2}\frac{|d|^2}{\|u\|^2}.
\]

\]

By definition of \( \nu_x \), we have \( (1 - \delta)|x_b| > \nu_x \), for \( \delta \in [0, 1] \), \( \forall b \in I \), and thus \( |x_b - x_b'| \leq \nu_x \leq (1 - \delta)|x_b| \). Lemma 10 then applies, and it follows that, \( \forall b \in I \)
\[
|\mathcal{N}(x_b) - \mathcal{N}(x'_b)| \leq C_\rho \frac{\|x'_b - x_b\|}{\|x_b\|} \leq C_\rho \frac{\|x'_b - x_b\|}{\nu_x},
\]
and therefore we get
\[
|\mathcal{N}(x) - \mathcal{N}(x')|_{\infty,2} \leq \frac{C_\rho}{\nu_x} \|x' - x\|_{\infty,2},
\]
48
Proof of Proposition 15. In general, the subdifferential of $J_0$ reads

$$\partial J_0(u) = \left\{ \sum_{i \in I} \rho_i s_i a^i : \rho \in \Sigma_I, s_i \in \{1 \text{ if } u_i > 0\}, [0,1] \text{ if } u_i = 0, \{0\} \text{ if } u_i < 0 \right\},$$

where $\Sigma_I$ is the canonical simplex in $\mathbb{R}^{|I|}$, and $I = \{i \in \{1, \cdots, N_H\} : (x_i)_+ = J_0(x)\}$.

- If $u_i \leq 0, \forall i \in \{1, \cdots, N_H\}$, the above expression becomes

$$\partial J_0(u) = \left\{ \sum_{i \in I_0} \rho_i s_i a^i : \rho \in \Sigma_{I_0}, s_i \in [0,1] \right\},$$

where $I_0 = \{i \in \{1, \cdots, N_H\} : u_i = J_0(u) = 0\}$. Equivalently, $\partial J_0(u)$ is the intersection of the unit $\ell_1$ ball and the positive orthant on $\mathbb{R}^{|I_0|}$. The expressions of $S_u, T_u$ and $e_u$ then follow immediately. $\partial J_0(u)$ then contains $e_u = 0$, but not in its relative interior. Choosing any $f_u$ as advocated, we have $f_u \in \partial \partial J_0(u)$. To get the antipromoting gauge, we some calculus rules on gauges and apply Lemma 3 to get

$$J^2_{f_u}(\eta_{I_0}) = \inf_{\tau \geq 0, \tau(f_u), 2-\eta, \forall i \in I_0} \max(|\tau f_u + \eta|_1, \tau),$$

where the extra-constraints on $\tau$ come from the fact that $\partial J_0(u)$ is in the positive orthant, and the $\ell^1$ norm is the gauge of the unit $\ell^1$-ball. We then have

$$J^2_{f_u}(\eta_{I_0}) = \inf_{\tau \geq \max(I_0) - \eta_i} \max(\tau \sum_{i \in I_0} (\mu a^i + \eta_i), \tau)$$

$$= \inf_{\tau \geq \max(I_0) - \eta_i} \max(\tau \mu |I_0| + \sum_{i \in I_0} \eta_i), \tau).$$

- Assume now that $u_i > 0$ for at least one $i \in \{1, \cdots, N_H\}$. In such a case, $J_0(u) = \|u\|_{\ell^\infty}$, and the subdifferential becomes

$$\partial J_0(u) = \Sigma_{I_u},$$

where $I_u \{i \in \{1, \cdots, N_H\} : u_i = J_0(u) \text{ and } u_i > 0\}$. The forms of $S_u, T_u, e_u, f_u$ and the antipromoting gauge can then be retrieved from those of the $\ell^\infty$-norm with $s_{(I_u)} = 1$ and $s_{(I_u^c)} = 0$.

For piecewise regularity, the parameters are derived following the same lines as for the $\ell^\infty$-norm. Let $u' \in T$, and assume that

$$\|u - u'\|_1 \leq \nu_u = (1 - \delta) \left( \max_{i \in I_u} u_i - \max_{j \in I_u^c, u_j > 0} u_j \right),$$

49
for $\delta \in [0, 1]$. This means that $x'$ lies in the relative interior of the $\ell^1$-ball (relatively to $T$) centered at $x$ of radius

$$
\max_{i \in I_+} u_i - \max_{j \notin I_+, u_j > 0} u_j = |u|_{\infty} - \max_{j \notin I_+, u_j > 0} |u_j|
$$

Within this set, one can observe that the set $I_+$ associated to $u$ is constant. Moreover, the sign pattern is also constant leading to the fact that $T_u = T'_u = T$. Hence, we deduce as in the $\ell^\infty$-case that $\mu_u = \tau_u = \xi_u = 0$.

**Proof of Proposition 16.** The subdifferential of the nuclear norm is a classical result in convex analysis of spectral functions, see e.g. [42, 22]. The expressions of the subspaces $T_x$, $S_x$ and $e_x$ follow immediately. Since the nuclear norm is a strong gauge, we get from Proposition 6 that the antipromoting gauge is the spectral norm.

Let’s turn to piecewise regularity. The proof is a straightforward adaptation of the arguments in [2, Proposition 16]. The latter result was stated for the spectral norm, but remains valid for the nuclear norm. □
