Abstract

This paper presents a likelihood ratio test based method of change detection and classification for synthetic aperture radar (SAR) time series, namely NORmalized Cut on chAnge criterion MAtrix (NORCAMA). This method involves three steps: 1) multi-temporal pre-denoising step over the whole image series to reduce the effect of the speckle noise; 2) likelihood ratio test based change criteria between two images using both the original noisy images and the denoised images; 3) change classification by a normalized cut based clustering-and-recognizing method on change criterion matrix (CCM). The experiments on both synthetic and real SAR image series show the effective performance of the proposed framework.

Keywords: NORmalized Cut on chAnge criterion MAtrix (NORCAMA), Change Criterion Matrix (CCM), Change detection, Change classification, Likelihood Ratio Test (LRT), SAR time series

1. Introduction

Change analysis in remote sensing images is the process of analyzing differences (including identifying, recognizing and so on) in regions of interest by observing them at different dates (Singh, 1989). Many applications of remote sensing images involve change analysis, such as rapid mapping of disaster, land-use and land-cover monitoring and so on. Lu et al. (2011) used change detection method to detect and locate the landslides for rapid mapping of landslides. Similarly, a multi-sensor change detection method between optical and synthetic aperture radar (SAR) imagery is proposed in (Brunner et al., 2010) for earthquake damage assessment of buildings. For urbanization monitoring, post-classification change detection methods are proposed (Taubenböck et al., 2012; Yin et al., 2011). From a methodological point of view, change analysis methods can be classified into two classes, binary-temporal change analysis and multi-temporal change analysis according to the number of images.

In the binary-temporal change analysis of two optical images, the most widely used operator is difference operator (Singh, 1989). For multi-spectral images, change vector analysis (Bruzzone and Prieto, 2000) is proposed. People also perform the analysis on the transformed data instead of the spectral data directly, such as Tasseled Cap transformation (Fung, 1990; Huang et al., 2002), principal component analysis (Fung and LeDrew, 1987; Deng et al., 2008) and independent component analysis (Marchesi and Bruzzone, 2009). Beyond change detection, Bruzzone and Serpico (1997) explicitly identified land-cover transitions (changes among Bare soil, Corn, Soybean, Sugar beet, Wheat) in multi-temporal remote-sensing images based on supervised classification. Given SAR images, two main approaches have been developed in the literature for change analysis: coherent change detection and incoherent change detection. The former uses the phase information in the SAR images through the study of the coherence map (Preiss and Stacy, 2006). In incoherent change detection, the log-ratio (Rignot and van Zyl, 1993) is the most common operator. Improvements have been proposed thanks to automatic thresholding methods (Bazi et al., 2005) or multi-scale analysis to preserve details (Bovolo and Bruzzone, 2005). Lombardo and Oliver (2001) proposed a generalized likelihood ratio test given by the ratio between geometric and arithmetic means for SAR images. Quin et al. (2013) extended this ratio of different means to a more general way with an adaptive and nonlinear threshold, which can be applied to not only SAR image pairs but also SAR time series.

Beyond change analysis between two dates, multi-temporal change analysis (more than 2 dates) mainly focuses on the long-term change information. SAR image features consisting of long-term coherence and temporal backscattering is proposed for a classification purpose (Bruzzone et al., 2004). Julea et al. (2011, 2012) propose a crop monitoring using satellite image time series by a frequent sequential pattern (a group of pixels sharing common temporal patterns and satisfying a minimum spatial connectivity). A generic change detection approach is proposed in (Verbesselt et al., 2010a) for multi-temporal images by detecting and characterizing breaks for additive seasonal and trend changes. It integrates the decomposition of time series into trend, seasonal, and remaining components within a long-term time series. An improved harmonic seasonal model which requires fewer observations has been presented in (Verbesselt et al., 2010b). Transform tools (De Jong et al., 2011; Martínez
and Gilabert, 2009) have also been used for analysis of the normalized difference vegetation index time series.

In this paper, we address the problem of change classification of multi-temporal SAR series. We will focus on same-sensor same-incidence case and particularly on urban areas. A motion of multi-temporal SAR series. We will focus on same-incidence case and particularly on urban areas. A motion of multi-temporal SAR series. We will focus on same-incidence case and particularly on urban areas.

In the pre-processing step, a multi-temporal SAR image filter is used to reduce speckle phenomenon. After that, two change criteria based on likelihood ratio test combining noisy and denoised data are developed and compared. The final step is a clustering-and-recognizing change classification based on the change criterion, in which changes are classified into different types (including step change, impulse change, cycle change and complex change). The last 2 steps as well as the global framework are the main contribution of this paper. Evaluation on synthetic and real images show the good performance of the proposed approach.

This paper is organized as follows. Section 2 briefly recalls the multi-temporal denoising method for SAR images. The proposed approximate likelihood ratio test and generalized likelihood ratio test change criteria are presented in Section 3. The proposed clustering-and-recognizing change classification method is then detailed in Section 4. This is followed by evaluation (Section 5) and conclusion (Section 6).

2. Pre-Processing: Multi-Temporal Denoising

When dealing with multi-temporal images, lots of information is available and useful for estimation in the time series. Based on this motive, we proposed a two-step probabilistic patch based (2SPPB) denoising method (Su et al., 2014) based on non local means (Buades et al., 2005) and probabilistic patch based weights (PPB) (Deledalle et al., 2009) adapted to multi-temporal SAR images. To allow a self-content reading of this paper and to introduce the useful notations, we briefly summarize the main steps of this approach. A complete description can be found in (Su et al., 2014). It consists of a temporal averaging step and a spatial denoising step (summarized in Algorithm 1).

Firstly, an average image is created by combining stable pixels while keeping unchanged the pixels not in accordance with the other dates (temporal averaging step). Then, on this improved image, a spatial denoising step is applied. A key point in both the temporal and spatial averaging is the weights based on the similarity between pixels, which are measured by similarity between patches. This section presents a brief summary of 2SPPB which will be useful for the following steps.

2.1. Pixel similarity

We denote by \( y_i \), the observed SAR image, by \( y_r(i) \) the noisy intensity value at pixel index \( i \) at time \( t \), and by \( \hat{u}_r(i) \) the estimation of the actual pixel value \( u_r(i) \) (the true value that we are looking for). Considering \( \{y_1, y_2, \ldots, y_n\} \) as the stack of multi-temporal images, the similarity \( S(i, i_r, h, h') \) between pixels \( y_r(i) \) and \( y_r(i) \) is defined through their patches \( y_r(i) \) and \( y_r(i) \):

\[
S(i, i_r, h, h') = \frac{S_{GLR}(y_r(i), y_r(i))}{h} + \frac{S_{KL}(\hat{u}_r(i), \hat{u}_r(i))}{h'}
\]

\( S(i, i_r, h, h') \) consists of a generalized likelihood ratio \( S_{GLR} \) (GLR) from noisy images \( y_i \) and \( y_r \) and a Kullback-Leibler divergence \( S_{KL} \) (KL) from currently denoised images \( \hat{u}_r \) and \( \hat{u}_r \). \( S_{GLR} \) and \( S_{KL} \) are normalized by parameters \( h \) and \( h' \). For any pair of pixels \( y_1 \) and \( y_2 \), the GLR criterion \( S_{GLR} \) is comparing two small square patches \( y_1 \) and \( y_2 \) of size \( K \) surrounding pixels at the positions of \( y_1 \) and \( y_2 \).

\[
S_{GLR}(y_1, y_2) = \sum_{k \in K} [(L_{1,k} + L_{2,k}) \log \{L_{1,k}y_{1,k} + L_{2,k}y_{2,k}\} - (L_{1,k} + L_{2,k}) \log \{L_{1,k} + L_{2,k}\} - L_{1,k} \log \{y_{1,k}\} - L_{2,k} \log \{y_{2,k}\}]
\]

where, \( y_{1,k} \) is pixel \( k \) in patch \( y_1 \) and \( L_{1,k} \) is the (equivalent) number of looks of \( y_{1,k} \) (idem for \( y_{2,k} \) and \( L_{2,k} \)). The KL criterion \( S_{KL} \) is computed iteratively from the denoised results \( \hat{u}_r \) and \( \hat{u}_r \) (corresponding to the noisy images \( y_i \) and \( y_r \)). For any pair of denoised pixels \( \hat{u}_1 \) and \( \hat{u}_2 \), \( S_{KL} \) is also defined on two patches \( \hat{u}_1 \) and \( \hat{u}_2 \).

\[
S_{KL}(\hat{u}_1, \hat{u}_2) = \sum_{k \in K} \left[ L_{1,k} \frac{\hat{u}_{1,k}}{\hat{u}_{1,k}} + L_{2,k} \frac{\hat{u}_{2,k}}{\hat{u}_{2,k}} - L_{1,k} - L_{2,k} + L_{1,k} \left[ \psi(L_{1,k}) - \psi(L_{2,k}) + \log(\hat{u}_{1,k}) + \log(\hat{u}_{2,k}) \right] \right.
\]

\[
+ L_{2,k} \left[ \psi(L_{1,k}) - \psi(L_{2,k}) + \log(\hat{u}_{1,k}) + \log(\hat{u}_{2,k}) \right]
\]

where \( \psi(L) \) is the digamma function.

2.2. Two steps denoising

The first step of 2SPPB is to average the temporal pixels with binary weights:

\[
y_r^{1st}(i) = \frac{1}{Z} \sum_{j \in [1,...,\kappa]} \varphi \left[ S \left( i, i_r, h_{1st}, h_{1st}^{1st} \right) \right] \cdot y_r(i)
\]

\[
\varphi \left[ S \left( i, i_r, h_{1st}, h_{1st}^{1st} \right) \right] = \begin{cases} 1, & \text{if } S \left( i, i_r, h_{1st}, h_{1st}^{1st} \right) < 1 \\ 0, & \text{otherwise} \end{cases}
\]

where, \( S \left( i, i_r, h_{1st}, h_{1st}^{1st} \right) \) is computed from noisy images \( y_i \) and \( y_r \), and denoised images \( \hat{u}_i^{ppb} \) and \( \hat{u}_r^{ppb} \) using PPB. The second step of 2SPPB approach is to exploit similar pixels in the temporally average image \( y_r^{1st} \) rather than in the stack \( y_1, \ldots, y_n \). The estimation at time \( t \) is thus given by

\[
\hat{u}_i(i) = \frac{1}{Z} \sum_{j \in [1,...,\kappa]} \exp(-S \left( i, j, h_{2nd}, h_{2nd}^{2nd} \right)) \cdot y_r^{1st}(j)
\]

where the GLR criterion \( S \left( i, j, h_{2nd}, h_{2nd}^{2nd} \right) \) is computed using the temporal step (the first step) result \( y_r^{1st} \). To improve the \( \hat{u}_i \) estimation, the KL criterion is iteratively refined by using the previous estimate \( \hat{u}_i \). The final result of this temporal denoising
step will be denoted by \( \hat{u}_t \) for date \( t \) (corresponding number of looks \( L_t \)). Algorithm 1 summarizes the multi-temporal denoising processing.

**Algorithm 1** The multi-temporal denoising (2S-PPB) algorithm.

**Input:**
- Registered temporal SAR images \( \{y_{t_1}, y_{t_2}, \ldots, y_{t_n}\} \).
- A date \( t_1 \) of interest.

**Output:**
- \( \hat{u}_{t_1} \): the denoising result of image \( y_{t_1} \).

**Step 1 (Temporal step):**
1. for each year \( y \) in \( \{y_{t_1}, y_{t_2}, \ldots, y_{t_n}\} \) do
2. denoise \( y \) using PPB filter (Deledalle et al., 2009);
3. obtain pre-denoised results \( \hat{u}_{t_1}^{PPB} \);
4. end for
5. for each pixel index \( i \) do
6. Calculate \( y_{t_1}^{PPB}(i) \); (Eq. 4)
7. end for

**Step 2 (Spatial step):**
8. Set \( \hat{u}_{t_1} = 1 \);
9. for Iteration from 1 to 10 do
10. for each pixel index \( i \) do
11. Calculate \( S(\hat{u}_{t_1}, \hat{u}_{t_2}, \hat{u}_{t_3}, \hat{u}_{t_4}) \) using \( y_{t_1}^{PPB}(i) \) and \( \hat{u}_{t_1}(i) \);
12. Update \( \hat{u}_{t_1}(i) \) using Eq.6;
13. end for
14. end for
15. return Denoised result \( \hat{u}_{t_1} \);

### 3. Change Detection

In statistics, change detection problem can be considered as a comparison of two hypotheses \( \mathcal{H}_0 \) and \( \mathcal{H}_1 \) (Radke et al., 2005):

\[
\mathcal{H}_0 : u_1 = u_2 = u_{12} \text{ (null hypothesis)} \\
\mathcal{H}_1 : u_1 \neq u_2 \text{ (alternative hypothesis)}
\]  

where \( \mathcal{H}_0 \) is unchanged case and hypothesis \( \mathcal{H}_1 \) is changed case. Likelihood ratio test is a state-of-the-art test which determines the decision by a likelihood ratio (Kay, 1998):

\[
R = \frac{p(Y|u_{12}, \mathcal{H}_0)}{p(Y|u_1, u_2, \mathcal{H}_1)}
\]  

where \( Y \) is the observed data. In this section, we propose to develop the likelihood ratio test using the multi-temporal denoising results. Contrary to most likelihood ratio tests which only use noisy data, both the denoised data and the noisy data are involved in the proposed criteria.

#### 3.1. Change Criterion by Approximate Likelihood Ratio Test

Recall that by \( y \) we denote a pixel intensity value. Under the speckle noise model described in (Goodman, 1976), \( y \) is a realization of a random number characterized by the Gamma probability density function (pdf) \( p(y|u) \). \( u \) is the parameter of this Gamma pdf or the noise-free pixel value. Under the test in Eq.8, the change criterion between \( y_1 \) and \( y_2 \) using likelihood ratio test can be defined as:

\[
\mathcal{R}^{ALRT}(y_1, y_2) = \frac{p(y_1, y_2|u_{12}, \mathcal{H}_0)}{p(y_1, y_2|u_1, u_2, \mathcal{H}_1)}
\]  

The criterion in Eq. 9 is a composite hypothesis problem because it requires the noise-free value \( u_1 \) and \( u_2 \) which are unavailable in practice. Instead of using usual generalized likelihood ratio extensions, we propose to use the estimated results \( \hat{u}_1 \) to replace the noise-free \( u_1 \) and \( u_2 \) and \( u_{12} = \hat{u}_1 + \hat{u}_2 \).

Combined with the Gamma probability density function, the likelihood ratio in Eq. 8 becomes:

\[
\mathcal{R}^{ALRT}(y_1, y_2) = \frac{p(y_1, y_2|u_{12}, \mathcal{H}_0)}{p(y_1, y_2|u_1, u_2, \mathcal{H}_1)} = \frac{1}{4} \left( \frac{\hat{u}_2}{\hat{u}_1} + \frac{\hat{u}_1}{\hat{u}_2} + 2 \right)^L \exp \left[ -L \left( \frac{y_1}{\hat{u}_1} + \frac{y_2}{\hat{u}_2} - 2\frac{y_1 + y_2}{\hat{u}_1} \right) \right]
\]  

where \( L \) is the original spatially-invariant (equivalent) number of looks. Note that the approximate likelihood ratio \( \mathcal{R}^{ALRT} \) highly depends on the denoised values \( \hat{u}_1 \) and \( \hat{u}_2 \), since \( \mathcal{R}^{ALRT}(y_1, y_2) \equiv 1 \) when \( \hat{u}_1 = \hat{u}_2 \).

#### 3.2. Change Criterion by Generalized Likelihood Ratio Test

In a more general way, we can take into account the denoised values and consider the likelihood probability of \( \mathcal{H}_0 \) and \( \mathcal{H}_1 \) as \( p(y_1, y_2, \hat{u}_1, \hat{u}_2|\mathcal{H}_0) \) and \( p(y_1, y_2, \hat{u}_1, \hat{u}_2|\mathcal{H}_1) \). To simplify this likelihood probability, we can assume that \( y_1, \hat{u}_1 \) and \( y_2, \hat{u}_2 \) are independent, although this assumption is not well justified. Thus,

\[
p(y_1, y_2, \hat{u}_1, \hat{u}_2|\mathcal{H}_0) = p(y_1, \hat{u}_1|u_{12}, \mathcal{H}_0)p(y_2, \hat{u}_2|u_{12}, \mathcal{H}_0) \\
p(y_1, y_2, \hat{u}_1, \hat{u}_2|\mathcal{H}_1) = p(y_1, \hat{u}_1|u_1, \mathcal{H}_1)p(y_2, \hat{u}_2|u_2, \mathcal{H}_1)
\]
The likelihood ratio test is given by:

$$
R_{GLRT}(y, y) = \frac{p(y_1, \hat{u}_1 | u_1, H_0)p(y_2, \hat{u}_2 | u_2, H_1)}{p(y_1, \hat{u}_1 | u_1, H_1)p(y_2, \hat{u}_2 | u_2, H_0)}.
$$

Since $u_1$, $u_2$ and $\hat{u}_1$, $\hat{u}_2$ are not available, they can be replaced by their maximum likelihood (ML) estimation:

$$
\begin{align*}
    u_1 &= \frac{L_y + \hat{L}_1 u_1}{L + \hat{L}_1}, \\
    u_2 &= \frac{L_y + \hat{L}_2 u_2}{L + \hat{L}_2}, \\
    u_{12} &= \frac{L_y + \hat{L}_1 u_1 + \hat{L}_2 u_2}{2L + \hat{L}_1 + \hat{L}_2}.
\end{align*}
$$

$L$, $\hat{L}_1$ and $\hat{L}_2$ are the number of looks of $y$, $\hat{u}_1$ and $\hat{u}_2$ respectively. Note that this is very similar to (Lombar do and Oliver, 2001). Nevertheless, the multi-temporal denoised values used in the proposed approach can provide more accurate estimation without loss of spatial resolution. It was not the case in (Lombar do and Oliver, 2001) where spatial partitioning and averaging are introduced. In case of Gamma distributions with different number of looks, each probability term $p(y, \hat{u}|u)$ in Eq.11 can be approximated under conditional independence assumption by:

$$
p(y, \hat{u}|u) = p(y|\hat{u})p(\hat{u}|u) = \frac{y^{-1}\alpha^{-1}}{\Gamma(L)\Gamma(L)} \exp \left( -\frac{L_y + \hat{L}_u}{u} \right).
$$

Finally, the change criterion by generalized likelihood ratio test is given by:

$$
R_{GLRT}(y_1, y_2) = \left( \frac{L_y + \hat{L}_1 u_1}{L + \hat{L}_1} \right)^{L_x+L_z} \left( \frac{L_y + \hat{L}_2 u_2}{L + \hat{L}_2} \right)^{L_x+L_z} \\
\left( \frac{2L + \hat{L}_1 + \hat{L}_2}{L_y + \hat{L}_1 u_1 + L_y + \hat{L}_2 u_2} \right)^{2L_x+L_z+L_z}.
$$

When $\hat{u}_1 = \hat{u}_2$, the generalized likelihood ratio $R_{GLRT}$ still depends on the noisy values $y_1$ and $y_2$ which is different from the approximate likelihood ratio $R_{ALRT}$.

### 3.3. Thresholds for Change Detection

In (Kervrann and Boulanger, 2006), the authors proposed to define the parameters according to the quantiles of the similarity criterion when it is subject to identical and independent distributed random variables. Pursuing this idea, we propose to choose the thresholds according to the quantiles of $R_{ALRT}$ and $R_{GLRT}$. The change detection threshold can be set by $\tau_{ALRT} = \text{quantile}(R_{ALRT}, \alpha = 0.01)$ (and $\tau_{GLRT} = \text{quantile}(R_{GLRT}, \alpha = 0.01)$), which means the false alarm rate is 1%. However, it is not easy to obtain the distribution of $R_{ALRT}$ and $R_{GLRT}$ since they depend on the number of looks of noisy images, the number of images used in the denoising process and all the parameters of multi-temporal filter (such as the $h$, $h'$, search window size, patch size and so on). Thus, $R_{ALRT}$ and $R_{GLRT}$ distributions are simulated using synthetic SAR images to choose the thresholds.

For our purpose of parameter setting, any picture can be used to generate multiple speckle images, such as the famous Lena image. Note that all the synthetic multi-temporal noisy images use the same true image, which guarantees no changes among them. The same number of images and the same number of looks as the real SAR images to be processed have to be used. Then, the multi-temporal denoising process in section 2 is performed. The approximate and generalized likelihood ratio test change criteria calculated from these images are considered as pure distributions of $R_{ALRT}$ and $R_{GLRT}$. As shown in Fig.2, the histograms of $R_{ALRT}$ and $R_{GLRT}$ are truncated by the thresholds (red lines) with false alarm 1%. The parts on the right of the thresholds are considered as unchanged case, the left part is changed case. Fig.3 shows the $R_{ALRT}$ and $R_{GLRT}$ histograms of changed and unchanged pixels in real SAR data Paris (image information detailed in section 5). Those changed pixels are labeled manually. The robustness of the proposed change criteria $R_{ALRT}$ and $R_{GLRT}$ can be epitomized by the overlap of $R_{ALRT}$ and $R_{GLRT}$ histograms.

### 4. Change Classification

Change analysis between 2 dates aims at detecting a binary pattern (change or no-change). When dealing with a multi-temporal data set (more than 2 dates), the analysis among them is much more complex. For instance, the temporal behaviors of a new building usually can be considered as a step change, which means that comparing the oldest date with other dates, it
Figure 3: An example of the normalized histograms of ALRT and GLRT using real SAR images Paris (detailed in section 5). The red lines are thresholds $\tau_{ALRT}$ and $\tau_{GLRT}$ with false alarm 1%. The blue lines are the histograms of unchanged $\mathcal{R}_{ALRT}$ and $\mathcal{R}_{GLRT}$. The green lines are the histograms of changed $\mathcal{R}_{ALRT}$ and $\mathcal{R}_{GLRT}$. was unchanged at the beginning but it changed since a certain date (shown in Fig. 4.a). Similarly, we can define the boats in rivers or cars on the roads as impulse changes (Fig. 4.b). These change information can be used in the multi-temporal image interpretation tasks. Therefore, a clustering-and-recognizing method is proposed to classify changes into different types. This method consists of two steps, clustering using normalized cut on a change criterion matrix (to assign a same label to similar or unchanged temporal pixels) and classification according to their temporal behaviors. The following subsections detail the proposed approach.

4.1. Change Criterion Matrix (CCM)

At position $i$ of a multi-temporal SAR series $\{y_1, \ldots, y_n\}$, we have the two pixel series $\{y_i(1), \ldots, y_i(n)\}$ (original noisy data), $\{\hat{u}_i(1), \ldots, \hat{u}_i(n)\}$ (denoised data by multi-temporal filter of section 2) and associated equivalent number of looks $[L_i(1), \ldots, L_i(n)]$. The change criterion matrix (CCM) at position $i$ is defined as:

$$M(i) = \begin{bmatrix} R(y_1, y_1) & R(y_1, y_2) & \ldots & R(y_1, y_N) \\ R(y_2, y_1) & R(y_2, y_2) & \ldots & R(y_2, y_N) \\ \vdots & \vdots & \ddots & \vdots \\ R(y_N, y_1) & R(y_N, y_2) & \ldots & R(y_N, y_N) \end{bmatrix}$$

(15)

where $R(y_n, y_m)$ shorts for $R[y_n(i), y_m(i)]$ denotes the change criterion ($\mathcal{R}_{ALRT}$ or $\mathcal{R}_{GLRT}$) between pixel $y_n(i)$ and $y_m(i)$. Note that $R(y_n, y_m) = 1$ when $n = m$. Contrary to the multi-date divergence matrix in (Atto et al., 2013) performing at the image or sub-image level, the CCM presents the change information at pixel level. Each CCM $M(i)$ denotes the temporal behavior of the pixel series at position $i$.

4.2. Clustering by Normalized Cut

Spectral clustering techniques make use of the similarity matrix of the data to perform clustering. Since the CCM can be
considered as a similarity matrix of the time series, spectral clustering method has been applied on CCM to cluster the temporal pixels. In this case, no more similarity measurements is needed compared with other clustering methods (like K-Means algorithm for which new similarity to cluster center has to be computed).

Normalized spectral clustering proposed by Shi and Malik (2000) is employed in this work, which can be summarized in Algorithm. 2. In this algorithm, the unnormalized Laplacian matrix $M^0(i)$ is computed by:

$$M^0(i) = M(i) - M(i)$$

$$M(i) = \begin{bmatrix}
\sum R(y_1, y_n) & 0 & \cdots & 0 \\
0 & \sum R(y_2, y_n) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \sum R(y_N, y_n)
\end{bmatrix}$$

$$\sum R(y_m, y_n) = \sum_{n=1}^{N} R(y_m, y_n)$$

The only parameter in Algorithm. 2 is the number of clusters $p$. Choosing the number of clusters $p$ is a general problem for all clustering algorithms, and a variety of successful methods have been devised (more details in (Von Luxburg, 2007)). Eigengap heuristic is one of them and particularly designed for spectral clustering. The main idea is to choose the number $p$ such that all eigenvalues $\lambda_1, \ldots, \lambda_p$ are very small, but $\lambda_{p+1}$ is relatively larger. However, this heuristic fails when the clusters of the data are overlapping (because of noise). To solve this problem, we binarize the CCM $M(i)$ using the change detection threshold.

$$M^0(i) = \begin{bmatrix}
R^0(y_1, y_1) & \cdots & R^0(y_1, y_N) \\
R^0(y_2, y_1) & \cdots & R^0(y_2, y_N) \\
\vdots & \vdots & \vdots \\
R^0(y_N, y_1) & \cdots & R^0(y_N, y_N)
\end{bmatrix}$$

$$R^0(y_m, y_n) = \begin{cases}
0 & \text{if } R^0(y_m, y_n) < \tau \\
1 & \text{if } R^0(y_m, y_n) \geq \tau
\end{cases}$$

The Eigengap heuristic performed on the binary change criterion matrix $M^0(i)$ can easily estimate the number of clusters $p$ (see the example shown in Fig. 5). The toy model in Fig. 5.a has 2 clusters. Using CCM $M(i)$ in 5.b, the difference between eigenvalues $\lambda_2$ and $\lambda_1$ is not large enough compared with the one between $\lambda_1$ and $\lambda_2$. It is very easy to find the best estimation of $p$ using the binary CCM $M^0(i)$ in 5.c because of the large gap between $\lambda_2$ and $\lambda_3$. It is obvious that this estimation of $p$ highly depends on the choice of the thresholds. However, the robustness of the proposed change criteria (especially $R^{GLRT}$ shown in Fig.3) can guaranty the estimation accuracy of $p$.

4.3. Recognizing

After clustering, each pixel series $\{y_1(i), \ldots, y_n(i)\}$ has a cluster label series $\{l_1(i), \ldots, l_n(i)\}$, in which $l_n \in \{1, \ldots, p\}$. We can identify different types of change according to the transformation in the cluster label series $\{l_1(i), \ldots, l_n(i)\}$. For example, if $p = 1$, there is no change among this pixel series. If $p = 2$ with cluster label series $\{1, 1, 1, 1, 2, 2, \ldots, 2\}$, it is a step change. Impulse change usually has $p = 2$ and cluster label series is $\{1, 1, 1, 1, 2, 2, \ldots, 1, 1, \ldots, 1\}$. When $p \geq 3$, the transformation is complex and changes are defined as complex case. According to these identifications (details in Table 4.3), changes can be classified into several classes.

5. Experiments

The proposed methods are evaluated on both synthetic images and real multi-temporal SAR images.

5.1. Experiments of Change Detection

5.1.1. Data Set

**Synthetic images:** Fig.6.a show the noisy synthetic images $y_t$ and $y_r$ corrupted by single-look multiplicative speckle noise respectively (with the ground truth of changes between them in Fig.6.a). The four squares are $32 \times 32$ pixels with true value 128. The darker frame is 8 pixels width with 32 as true value and the true value of background is 64.

**Realistic SAR Synthetic Images:** A denoised image of 21 single-look TerraSAR-X band images in Paris (France) sensed in 2011 is considered as the noise-free image (multi-temporal denoising approach in section 2), as shown in Fig.6.b. Two single-look noisy images $y_t$ and $y_r$ are generated with changes added in $y_r$. These changed regions are about 15-25 pixels.

---

**Algorithm 2 Clustering of the pixel series (Normalized spectral clustering (Shi and Malik, 2000))**

**Input:**

- A change criterion matrix $M(i)$ of pixel series $\{y_1(i), \ldots, y_n(i)\}$, number $p$ of clusters to construct.

**Output:**

- The clustering labels $\{l_1(i), \ldots, l_n(i)\}$ for pixel series $\{y_1(i), \ldots, y_n(i)\}$

1. Compute the unnormalized Laplacian matrix $M^0(i)$ using Eq.16.
2. Compute the first $p$ generalized eigenvectors $v_1, \ldots, v_p$ of $M^0(i)$ $(M^0(i)v = \lambda v)$.
3. Let $\nu$ be the matrix containing the vectors $v_1, \ldots, v_p$ as columns.
4. Consider each row of $\nu$ as a sample, $\nu' = [\nu_1', \ldots, \nu_N']$.
5. Cluster the samples $\nu_1', \ldots, \nu_N'$ with the k-means algorithm into clusters with $p$ as the number of clusters. The cluster labels of $\nu_1', \ldots, \nu_N'$ are $l_1', \ldots, l_n'$ ($l_n \in \{1, \ldots, p\}$).
6. return Cluster labels $l_1', \ldots, l_n'$.

**Table 1:** The identifications of different types of change.
changes is labeled manually in Fig.7.c. The change detection results are assessed by the True-Positive versus False-Positive curves using the reference map of changes. Fig.6.c and Fig.7.c show the the True-Positive versus False-Positive curves. The proposed methods $R^{ALRT}$ and $R^{GLRT}$ can generally obtain higher ROC curves than others. The experiments on CARABAS and Sendai data in Fig.9 and 10 show that the proposed GLRT change detection has comparable performance with MIMOSA (Quin et al., 2013). $R^{ALRT}$ and $R^{GLRT}$ outperform other change criteria, but the latter is more reliable than the former (the ROC curves of $R^{GLRT}$ are higher than $R^{ALRT}$ in Fig.6 and 11).

5.2. Experiments of Change Classification

5.2.1. Test on realistic SAR synthetic images

This experiment use one denoised image of 21 single-look TerraSAR X-band images of Paris (France) sensed in 2011 as the noise-free image (multi-temporal denoising approach in section 2), as shown in Fig.6.a. 6 single-look images are generated with different changes added in them. As shown in Fig.6.c, different kinds of changes have been introduced, such as step change (in red), impulse change (in green) and cycle change (in blue). Fig.6.d shows the change classification result by $R^{GLRT}$ with confusion matrix shown in Tab.5.2.1.

San-Francisco, U.S.A. 2007 and 2011. These images have been accurately registered using the sensor parameters. Fig.12.a and b only show the first noisy image and its denoising result. Fig.12.c shows the results of the change classification approach by $R^{GLRT}$, in which red regions denote step changes, green are impulse changes and blue are cycle changes. We can observe that many boats in river have been classified as impulse change. To analyze the performance of change classification, some interesting regions (examples of step change, impulse change, cycle change and complex change) of all the dates have been shown in Fig.13.

6. Conclusion

In this work, a global framework NORmalized Cut on chAnge criterion MAtrix (NORCAMA) for change classification of multi-temporal SAR time series has been presented. To reduce the effect of speckle, a multi-temporal denoising approach is applied in the pre-processing step. Using both noisy data and denoised data, the approximate likelihood ratio and the generalized likelihood ratio are computed as change criteria. The change classification is performed by clustering on change criterion matrix and classifying of label transformation. Different types of change, like step changes, impulse changes and cycle changes, have been defined by the proposed method, which can be used for multi-temporal SAR image interpretation. Note that the methods in the 3 steps of the proposed framework can be replaced by alternative methods, for instance other denoising approaches for the pre-processing step and other change criteria for the change detection step.

The future work will be focused in introducing spatial information into change analysis such as combining types of change and shapes to identify objects and developing a temporal-spatial SAR image analysis framework. The spatial information should allow us to extend this approach to multi-occurrence images.

Acknowledgment

The authors would like to thank Jean-Marie Nicolas for his help on image registration, the IGARSS Data Fusion Contest for providing the multi-temporal SAR images and the Department of Radar Systems, Swedish Defense Research Agency (FOI), for the CARABAS-II data distribution. They also wish to acknowledge the German Aerospace Agency (DLR) for the Terra-SAR-X images (project MTH0232 and LAN1746).
