Hypergraphs and degrees of parallelism:
a completeness result

Abstract. In order to study relative PCF-definability of boolean functions, we associate a hypergraph \( H_f \) to any boolean function \( f \) (following [2, 4]). We introduce the notion of timed hypergraph morphism and show that it is:

- Sound: if there exists a timed morphism from \( H_f \) to \( H_g \) then \( f \) is PCF-definable relatively to \( g \).
- Complete for subsequential functions: if \( f \) is PCF-definable relatively to \( g \), and \( g \) is subsequential, then there exists a timed morphism from \( H_f \) to \( H_g \).

1 Introduction

PCF is a simple, paradigmatic functional programming language, defined by D. Scott in his seminal paper [10], a milestone in the area of denotational semantics. Following Scott, Plotkin studied in [7] the relationship between operational and denotational semantics of PCF. The main results of [7] may be summarized as follows:

- The Scott model of PCF is adequate with respect to contextual equivalence.
- The model is not complete, due to the presence of non-definable, “parallel” functions.
- All the (algebraic) elements of the model become definable if a parallel conditional statement is added to the language.

Since then, a lot of work has been devoted to the search of a satisfactory semantic characterization of the notion of PCF-definable function (see [1] for a survey). We have now a number of different notions of sequentiality, and all of them characterize exactly PCF definability for first order functions.

In this paper, we study the relative definability problem for Finitary PCF (FPCF) with respect to its Scott model. FPCF is the finitary fragment of PCF: it has a single ground type \( \texttt{B} \), the corresponding constants \( \perp, \texttt{tt}, \texttt{ff} \), and just one more constant, the \( \texttt{if} \rightarrow \texttt{then} \rightarrow \texttt{else} \).

The Scott model of FPCF is the finite type hierarchy where \([\texttt{bool}]\) is the flat domain of boolean values, and \([\sigma \rightarrow \tau]\) is the set of monotonic functions from
to $[\sigma]$, ordered pointwise. FPCF-terms are interpreted in the standard way in this model, and in particular, for every closed term $M : \sigma$, $[M] \in [\sigma]$.

An instance of the relative definability problem is a pair $f \in [\sigma], g \in [\tau]$, and a solution is either a term $M : \tau \to \sigma$ such that $[M] g = f$, or a proof that such a term does not exist (when $M$ does exist, we say that $f$ is less parallel than $g$, and we write $f \leq_{\text{par}} g$).

Conceptually, the relative definability problem for the finitary fragment of PCF is settled: we know that it is undecidable in general [6] and decidable for functions of order 1 or 2 [11].

Nevertheless, decidability results may be not completely satisfactory: from a theoretical point of view, we still lack a characterization of the poset of degrees of parallelism (i.e. equivalence classes of inter-definable functions, noted $[f]$) which, even in the decidable case, is rich and complex [2, 8].

In this paper, we give a complete, geometric characterization of relative definability for “subsequential”, first-order functions; the exact correspondence we establish between geometric objects (a particular kind of hypergraph morphisms) and computational ones (the terms solving relative definability problems), is, we believe, interesting in itself.

Moreover, our analysis of relative definability problems provide a simple way of choosing, among the terms solving a given instance, an “optimal” one (for instance, a term defining $f$ with as few calls of $g$ as possible).

1.1 Related works

The study of degrees of parallelism was pioneered by Sazonov and Trakhtenbrot [9, 13] who singled out some finite subposets of degrees. Some results on degrees are corollaries of well known facts: for instance Plotkin’s full abstraction result for PCF+por implies that this poset has a top. The bottom of degrees is the set of PCF-definable functions which is fully characterized, for first order functions, by the notion of sequentiality (in any of its formulations). Moreover Sieber’s sequentiality relations [11] provide a characterization of first-order degrees of parallelism and this characterization is effective: given $f$ and $g$ one can decide if $f \leq_{\text{par}} g$. A. Stoughton [12] has implemented an algorithm which solves this decision problem. R. Loader has shown that the problem of deciding if a given continuous function(al) is PCF-definable, is undecidable [6]. As a consequence, the relation $\leq_{\text{par}}$ is undecidable in general (at higher-order), since, if $g$ is PCF-definable and $f$ continuous, then $f$ is PCF-definable if and only if $f \leq_{\text{par}} g$.

In [2], the first author investigates the poset of degrees of parallelism using categories of hypergraphs for representing boolean function. The starting point of the investigation was the observation that the trace of a function $f$ (i.e. the subset of the graph of $f$ whose first projection is the set of minimal points on which $f$ is defined) can be turned into a hypergraph $H_f$, in such a way that hypergraph morphisms from $H_f$ to $H_g$ are “witnesses” of the inequality $f \leq_{\text{par}} g$. In particular, a rich subposet of degrees for which the hypergraph representation is sound and complete is singled out in [2]. If $[f], [g]$ belong to that subposet $f \leq_{\text{par}} g$ holds if and only if there exists a morphism from $H_f$ to $H_g$. In [4] P.
Malacaria and the first author showed a general result about hypergraphs and degrees: if there exists a morphism from $H_f$ to $H_g$, then $f \leq_{par} g$. However, for the notion of hypergraph morphism they used (the standard one, based on the preservation of hyperarcs), no general completeness result seems to hold.

1.2 Plan of the paper

In this paper we introduce a weaker notion of hypergraph morphism (the timed morphisms) and we show that it is sound in general, and complete for subsequential functions (i.e. for functions which have a sequential upper bound). The proof of soundness presented in [4] goes through the framework of timed morphisms with some very minor changes. The proof of completeness is an application of Sieber’s sequentiality relations.

In Section 2 we introduce the notions of hypergraphs representing boolean functions and of $h$-morphisms between them ($h$-morphisms were called “weak” in [4]; since timed morphisms are weaker, we change the terminology here). In Section 3 the “timed” hypergraph morphisms are defined, and we show by some examples how they behave as boolean function transformers. In Section 4, we recall some useful properties of subsequential functions. Sections 5,6 and 7 are devoted to the proof of soundness and completeness of timed morphisms w.r.t. the relation $\leq_{par}$.

2 Hypergraphs and $h$-morphisms

We denote by $B$ the flat domain of boolean values $\{\bot, \tt, \ff\}$. Tuples of boolean values are ordered componentwise. Given a monotone function $f : B^n \to B$, the trace of $f$ is defined by

$$\text{tr}(f) = \{(v,b) \mid f(v) = b \neq \bot \text{ and } v \text{ minimal}\}$$

We note the first and second projection $\pi_1$ and $\pi_2$. In particular, $\pi_1(\text{tr}(f))$ is the set of minimal points where $f$ is defined.

A subset $A = \{v_1, \ldots, v_k\}$ of $B^n$ is linearly coherent (or simply coherent) if for all $1 \leq i \leq n$ either $\exists 1 \leq j \leq k$, $v_i^j = \bot$, or $\forall 1 \leq j, j' \leq k, v_i^j = v_i^{j'}$. The set of coherent subsets of $B^n$ is denoted $C(B^n)$. The coherence is related to sequentiality: if $f$ is a $n$-ary boolean function, and $\pi_1(\text{tr}(f))$ is coherent, then $f$ has no sequentiality index and it is not PCF-definable. Actually $f$ is definable if and only if no subset of $\pi_1(\text{tr}(f))$ is coherent.

The following easy property of the coherence will be useful:

**Fact 1.** If $A \in C(B^n)$ and $B$ is an Egli-Milner lower bound of $A$ (that is if $\forall x \in A \exists y \in B \ y \leq x$ and $\forall y \in B \exists x \in A \ y \leq x$) then $B \in C(B^n)$.

**Definition 1.** A colored hypergraph $H = (V_H, A_H, C_H)$ is given by:

- a finite set $V_H$ of vertices,
- a set \( A_H \subseteq \{ A \subseteq V_H | \# A \geq 2 \} \) of (hyper)arcs,
- a coloring function \( C_H : V_H \rightarrow \{ b, w \} \).

**Definition 2.** Let \( f : \mathcal{B}^n \rightarrow \mathcal{B} \) be the \( n \)-ary function defined by \( \text{tr}(f) = \{(v_1, b_1), \ldots, (v_k, b_k)\} \). The hypergraph \( H_f \) is defined by

- \( V_{H_f} = \pi_1(\text{tr}(f)) \),
- \( A_{H_f} \) contains the coherent subsets of \( \pi_1(\text{tr}(f)) \) with at least two elements,
- \( C_{H_f}(v_i) = \begin{cases} w \text{ if } b_i = \text{tt} \\ b \text{ if } b_i = \text{ff} \end{cases} \)

One can check that the hypergraphs associated to monotone functions by the definition above (functional hypergraph) verify the following conditions:

H1 : If \( \{ x, y \} \in A_H \) then \( C_H(x) = C_H(y) \).
H2 : If \( X_1, X_2 \) are hyperarcs and \( X_1 \cap X_2 \neq \emptyset \) then \( X_1 \cup X_2 \) is a hyperarc.

**Definition 3.** A \( h \)-morphism from a hypergraph \( H \) to a hypergraph \( K \) is a function \( m : V_H \rightarrow V_K \) such that:

- For all \( A \subseteq V_H \), if \( A \in A_H \) then \( m(A) \in A_K \).
- For all \( X \in A_H \), if \( x, x' \in X \) and \( C_H(x) \neq C_H(x') \) then \( C_K(m(x)) \neq C_K(m(x')) \).

Colored hypergraphs and \( h \)-morphisms form a category, \( \mathcal{H} \). In [4], it has been proved that, if there exists a \( h \)-morphism from \( H_f \) to \( H_g \), then \( f \leq_{\text{par}} g \). The problem of finding a weaker notion of hypergraph morphism, for which some sort of completeness result would hold, was left open.

We give here the motivating example for the definition of timed morphisms. Let \( \text{por}_2 : \mathcal{B}^2 \rightarrow \mathcal{B} \) and \( \text{por}_3 : \mathcal{B}^3 \rightarrow \mathcal{B} \) be defined by

\[
\text{por}_2(x, y) = \begin{cases} \text{tt} \text{ if one of } x, y \text{ is } \text{tt} \\ \bot \text{ otherwise} \end{cases}
\]

\[
\text{por}_3(x, y, z) = \begin{cases} \text{tt} \text{ if one of } x, y, z \text{ is } \text{tt} \\ \bot \text{ otherwise} \end{cases}
\]

The associated hypergraphs are:

\[
\begin{array}{c}
\text{tt} \\
\text{tt} \\
\text{tt} \\
\text{tt} \\
\end{array}
\]

It is easy to see that there exists no \( h \)-morphism \( m : H_3 \rightarrow H_2 \). Nevertheless \( \text{por}_3 \leq_{\text{par}} \text{por}_2 \), since for instance \( \text{por}_3 = [M] \text{por}_2 \) where

\[
M = \lambda f \; \lambda x_1 x_2 x_3 \; \text{if } f(x_1, x_2), x_3) \text{ then } \text{tt} \text{ else } \bot
\]

The tree of nested calls to \( f \) in \( M \) (the nesting tree of \( M \)), where the nodes are the occurrences of \( f \), and the links are the arguments of \( f \), is:
Actually, the nesting of calls to $f$ in the term which defines $\text{por}_3$ with respect to $\text{por}_2$ is necessary. By looking at the way $M$ “maps” the minimal points of $\text{por}_3$ onto the ones of $\text{por}_2$, we realize that at the outermost level $(\text{tt}, \bot, \bot)$ and $(\bot, \text{tt}, \bot)$ are both mapped on $(\text{tt}, \bot)$, while $(\bot, \bot, \text{tt})$ is mapped on $(\bot, \text{tt})$. The internal call of $f$ maps $(\text{tt}, \bot, \bot)$ on $(\text{tt}, \bot)$ and $(\bot, \text{tt}, \bot)$ on $(\bot, \text{tt})$.

3 Timed Morphisms

The idea is the following: we want to allow morphisms to “collapse” an hyperarc on a singleton, provided that we have another morphism mapping this hyperarc on a hyperarc. More precisely, we want a finite sequence of morphisms $m_1 \ldots m_l$ with domains $D_i \in A_H$, such that if $m_i$ collapses an hyperarc $B$, there exists $m_{i+k}$ with domain $B$. In the proof of soundness, each step in the sequence will appear as a nesting in the term.

For our example, the sequence corresponding to $M$ is:

In general, by looking at the morphism, one can easily see the nesting of calls to the defining function (and then build a term quite easily). First, we spot the vertices of $H_g$ corresponding to each argument of $g^1$: $\text{tt}$, $\bot$ for the first argument, $\bot$, $\text{tt}$ for the second. Then, we know how to organize the nested calls to $g$: if we collapse an hyperarc $X$ on the vertex corresponding to the argument $i$, we put a call to $g$ at argument $i$, which will be defined by the morphism with domain $X$.

For example, let $f(x, y)$ be $\text{tt}$ whenever $x$ or $y$ is defined, and $\bot$ elsewhere. $H_f$ is

---

1 In the general case, one cannot associate vertices to an argument. In our example $\text{por}_2$, this is obvious. For more details, see the proof of soundness.
The only subsets that are not coherent are \{tt\_\perp, ff\_\perp\} and \{tt\_\perp, ff\_\perp\}. In the following, we will not put the hyperarcs again. Here is a timed morphism from \(H_f\) to \(H_2\), and the corresponding term \(\lambda g \alpha x \lambda y M\) defining \(f\) with \(\text{por}_2\):

\[
M = g(\text{if } y \text{ then } \perp \text{ else } \text{tt},\ N)
\]

\[
N = g(\ P, \text{if } x \text{ then } \perp \text{ else } \text{tt})
\]

\[
P = g(\text{if } y \text{ then } \text{tt else } \perp, \text{if } x \text{ then } \text{tt else } \perp)
\]

The corresponding tree is:

But one can also easily find morphisms (and terms) for these nesting trees (and for some others, too):

The smallest nesting tree correspond to the “natural” solutions to this relative definability problem, namely:

\[
\lambda g \lambda x \lambda y \ g(\text{if } x \text{ then } \text{tt else } \text{tt}, \text{if } y \text{ then } \text{tt else } \text{tt})
\]
Timed morphisms are sequences. For a given problem, shorter sequences correspond to terms with smaller depth, w.r.t. the nesting of calls of $g$. Timed morphisms provide a handy tool for constructing these optimal solution.

Actually, we give a more abstract, equivalent definition of timed morphisms. We will argue that the two notions coincide after the following couple of definitions.

**Definition 4.** Let $H = (V_H, A_H, C_H)$ be a (functional) hypergraph.

- The **timed image** of $H$, $\overline{H}$ is defined by: $V_{\overline{H}} = V_H$, $C_{\overline{H}} = C_H$ and $A_{\overline{H}} = A_H \cup \{\{v\} \mid v \in V_H\}$.
- Let $B \subseteq V_H$. $H_{|B}$ is the sub-hypergraph of $H$ defined by:

$$
\begin{align*}
V_{H_{|B}} &= B \\
A_{H_{|B}} &= \{X \in A_H \mid X \subseteq B\} \\
C_{H_{|B}} &= (C_H)_{|B}
\end{align*}
$$

Given two functional hypergraphs $H, K$, we say that a morphism $\alpha \in \mathcal{H}(H, K)$ is non-trivial if $\#\alpha(V_H) > 1$.

**Definition 5.** Let $H, K$ be functional hypergraphs; a **timed morphism** $\alpha \in T\mathcal{H}(H, K)$ is a collection

$$
\{\alpha_X \in \mathcal{H}(H_{|X}, K)\}_{X \in A_H}
$$

where all the $\alpha_A$’s are non-trivial, and non-redundant in the following sense:

$$
\forall X \subseteq Y \in A_H \ \alpha_Y|_X \text{ is non trivial} \Rightarrow \alpha_X = \alpha_Y|_X
$$

The intuitive description of timed morphisms in terms of sequences, given in the examples of this section coincides with the definition above. Given a sequence $m = m^1, \ldots, m^k$ of $h$-morphisms from $H$ to $K$, and a hyperarc $X \in A_H$, define $\alpha^X_X = m^j|_X$, where $j$ is the smallest index such that $m^j|_X$ is non trivial. Conversely, given $\{\alpha^X_X\}_{X \in A_H}$ we have to construct a sequence of morphisms $m^1, \ldots, m^k$ from (restrictions of) $H$ to $K$, such that if $m^1$ collapses an hyperarc $B$, there exists $m^{i+k}$ non-trivial of domain $B$. Let $\{A_i\}_{i \in I}$ be the set of maximal elements of $V_H$ (note that these are disjoint, $H$ being functional); $m^1$ is obtained by “gluing” all the $\alpha_{A_i}$, $i \in I$. Now, letting $\{A_i\}_{i \in J} J = \{j^1, \ldots, j^l\}$ be the set of maximal elements of $V_H$ which are “collapsed” by $m^1$, we define $m^2 = \alpha_{A_1}, \ldots, m^{l+1} = \alpha_{A_{j^l}}$, and we proceed by considering the hyperarcs collapsed by $m^2, \ldots, m^{l+1}$. By finiteness of $H$, iterating this construction we obtain a sequence $m^1, \ldots, m^k$ obeying the definition of timed morphism in terms of sequences.

Timed morphisms compose componentwise (i.e. $(\alpha \circ \beta)|_A = \alpha_{\beta(A)} \circ \beta_{A}$). To any $h$-morphism $m : H \rightarrow K$ corresponds canonically the timed morphism defined by $\alpha_A = m|_A$. 

4 Subsequential Functions

A monotone function \( f : B^n \to B \) is **subsequential** if it is extensionally upper bounded by a sequential (i.e., PCF-definable) function. As shown in proposition 6 subsequential functions correspond to hypergraphs with monochromatic hyperarcs and to functions preserving linear coherence. Such a class of functions admits hence a natural characterization in order theoretic, graph theoretic and algebraic terms.

**Proposition 6.** Let \( f : B^n \to B \) be a monotone function. The following are equivalent:

1. \( f \) is subsequential.
2. For all \( A \in \mathcal{C}(B^n) \), \( f(A) \in \mathcal{C}(B) \). (i.e. \( f \) preserves the linear coherence of \( B^n \).)
3. If \( X \in A_{H_f} \), then for all \( x, y \in X \) \( C_{H_f}(x) = C_{H_f}(y) \) (i.e. \( X \) is monochromatic).

A proof can be found in [4].

Given a set \( A = \{v_1, \ldots, v_k\} \subseteq B^n \), there exist in general a number of functions whose minimal points are exactly the elements of \( A \). For instance, if the \( v_i \) are pairwise unbounded, there exist \( 2^k \) such functions. The following lemma states that, among these functions, the subsequential ones are those whose degree of parallelism is minimal.

**Lemma 7.** Let \( f, g : B^n \to B \) be such that \( g \) is subsequential and \( \pi_1(\text{tr}(f)) = \pi_1(\text{tr}(g)) \). Then \( g \preceq_{\text{par}} f \).

**Proof.** Let \( M \) be a PCF term which defines a sequential upper bound \( \overline{g} \) of \( g \). Let us define \( g_0 : B^n \to B \) by:

\[
g_0 = [\lambda f \lambda x. \text{if } f x \text{ then } M x \text{ else } M x] f
\]

If we prove that \( g_0 = g \) we are done. Let \( \pi = (a_1, \ldots, a_n) \in B^n \), and suppose \( g(a) = b \neq \bot \); then \( f(a) \neq \bot \) and \( \overline{g}(a) = b \), hence \( g_0(a) = b \). If \( g(a) = \bot \), then \( f(a) = \bot \), hence \( g_0(a) = \bot \) too. Conversely if \( g_0(a) = b \neq \bot \) then \( f(a) \neq \bot \) and hence \( g(a) \neq \bot \) as well. Since \( g(a) \leq \overline{g}(a) = b \), we get \( g(a) = b = g_0(a) \). If \( g_0(a) = \bot \), then \( f(a) = \bot \) or \( \overline{g}(a) = \bot \), and in each case \( g(a) = \bot \).

In section 5, we prove that if there exists a timed morphism \( \alpha : H_f \to H_g \), then \( f \preceq_{\text{par}} g \). The following lemma introduces a key notion toward that result, namely that of *slice function*. The idea is the following: in order to reduce \( f : B^n \to B \) to \( g : B^n \to B \) we start by transforming the minimal points of \( f \) into the ones of \( g \). This amounts to defining a function from \( B^n \) to \( B^n \), that we describe as a set of functions \( f_1, \ldots, f_n : B^n \to B \). If these functions are \( g \)-definable, then we can already \( g \)-define a function which is defined (that is, not equal to \( \bot \)) if and only if \( f \) is defined, namely

\[
h = \lambda x. g(f_1 x) \ldots (f_n x)
\]
and we are left with the problem of forcing $h$ to agree with $f$ whenever it converges.

For the time being we show that, if the $f_i$’s are defined via a timed morphism $\alpha : H_f \to H_g$, then they are subsequential, hence “relatively simple”.

**Lemma 8.** Let $f : B^m \to B$, $g : B^n \to B$ be monotone functions and $\alpha : H_f \to H_g$ be a timed morphism. For $B \in A_{H_f}$, $1 \leq i \leq n$ let $f_i^B : B^m \to B$ be the function defined by

$$\text{tr}(f_i^B) = \{(v, \alpha_B(v))| v \in B, \alpha_B(v) \neq \bot\}$$

Then $f_i^B$ is subsequential. We will call $f_i^B$ the $i$th–slice of $\alpha_B$.

**Proof.** Given $A \subseteq \text{tr}(f_i^B)$ such that $\pi_1(A) \in C(B^m)$, if $\pi_2(A) \notin C(B)$ then $\alpha_B$ maps the coherent set $\pi_1(A)$ onto a non coherent set. This cannot be the case by definition of timed morphism.

## 5 Soundness

Timed morphisms are sound with respect to $\leq_{\text{par}}$, in the sense expressed by the following theorem:

**Theorem 9.** Let $f : B^i \to B$, $g : B^m \to B$ be monotone functions such that $\mathcal{T}H(H_f, H_g) \neq \emptyset$. Then $f \leq_{\text{par}} g$.

The proof, which can be found in App. A is essentially the same as in [4]. The key point lies in the restriction of morphisms to a hypergraph. In [4], the hypothesis was too strong: we only need a morphism from this hyperarc to $H_g$, we do not need it to be a part of the initial morphism from $H_f$ to $H_g$. This generalization allow us to prove a completeness result.

This soundness result allow to derive easily corollaries on degrees of parallelism; for instance, in order to check that $[\text{por}_2]$ (from our motivating example) is the top of subsequential degrees (i.e. of degrees of subsequential functions; note that a subsequential function and a non-subsequential one cannot have the same degree of parallelism) it is sufficient to remark that, if $f$ is subsequential, a timed morphism from $H_f$ to $\text{por}_2$ is simply a (non-trivial and non redundant) partition of any hyperarc of $H_f$.

## 6 Sequentiality relations

**Definition 10** (Sieber). For each $n \geq 0$ and each pair of sets $A \subseteq B \subseteq \{1, \ldots, n\}$ let $S^n_{A,B} \subseteq B^n$ be defined by

$$S^n_{A,B}(b_1, \ldots, b_n) \Leftrightarrow (\exists i \in A \; b_i = \bot) \lor (\forall i, j \in B \; b_i = b_j)$$

An $n$-ary logical relation $R$ is called a sequentiality relation if it is an intersection of relations of the form $S^n_{A,B}$.

We define $S_{n,n+1} = S^{n+1}_{\{1, \ldots, n\}, \{1, \ldots, n+1\}}$. 

We write
\[ \begin{pmatrix} x_{11} & \cdots & x_{1n} \\ \vdots & \vdots & \vdots \\ x_{m1} & \cdots & x_{mn} \end{pmatrix} \in R \]
meaning that each row is in \( R \). A function \( f : B^m \to B \) is invariant under the logical relation \( R \) of arity \( n \) whenever the matrix \((x_{ij})_{1 \leq i \leq m, 1 \leq j \leq n}\) is in \( R \):
\[ (f(x_{11}, \ldots, x_{m1}), \ldots, f(x_{1n}, \ldots, x_{mn})) \in R \]

**Proposition 11.** For any \( f : B^n \to B \) and \( g : B^m \to B \) continuous functions, \( f \leq_{\text{par}} g \) if and only if for any sequentiality relation \( R \), if \( g \) is invariant under \( R \) then \( f \) is invariant too.

Actually this is a relativized version of the main theorem of [11]: a continuous function of first or second order is PCF-definable if and only if it is invariant under all sequentiality relations.

Coherence is tightly related to sequentiality relations:

**Lemma 12.** Let \( A = \{x_1, \ldots, x_n\} \subseteq B^m \), and \( B \) be a subset of \( \{1, \ldots, n\} \). \( \{x_i\}_{i \in B} \) is coherent iff \((x_{ij}) \in S_{B,B}^n\). Moreover, \( A \) is coherent iff:
\[ \begin{pmatrix} x_{11} & \cdots & x_{1n} \\ \vdots & \vdots & \vdots \\ x_{m1} & \cdots & x_{mn} \end{pmatrix} \in S_{n,n+1} \]

These sequentiality relations are closely related to strong stability at first order (see [3] from an overview on strong stability): \( f \) is strongly stable if it preserves linear coherence (that is, \( f \) is invariant by the relations \( S_{n,B,B}^n \)), and \( f \) is conditionally multiplicative: if \( A \) is coherent \( f(\bigwedge A) = \bigwedge_{a \in A} f(a) \), (that is, \( f \) is invariant for the relation \( S_{n,n+1} \)).

### 7 Completeness

**Theorem 13.** Let \( f : B^n \to B \) and \( g : B^m \to B \) be subsequential functions, such that \( \mathcal{T}(H_f, H_g) = \emptyset \). Then \( f \not\leq_{\text{par}} g \).

**Proof.** The first remark is that \( \mathcal{T}(H_f, H_g) = \emptyset \) if and only if there exists \( A \in A_H \), such that there is no non-trivial morphism from \( H_f|_A \) to \( H_g \). Throughout this proof, we restrict our attention to \( H_f|_A \), for such an \( A = \{v_1, \ldots, v_k\} \). Let \( A_1, \ldots, A_l \) be the arcs of \( H_f|_A \), and, for \( 1 \leq j \leq l \), let \( B_j \) be the corresponding set of the indices: \( A_j = \{v_i\}_{i \in B_j} \).

We consider the \((k+1)\)-ary sequential logical relation
\[ S_A = ( \bigcap_{1 \leq j \leq l} S_{B_j,B_j}^{k+1}) \cap S_{k,k+1} \]
If we prove that \( g \) is invariant with respect to \( S_A \) and \( f \) is not, we are done.

Let us start by proving that \( f \) is not invariant. Let \( V = (v_1, \ldots, v_l, \bigwedge_{1 \leq j \leq k} v_j) \); by lemma 12, for \( 1 \leq j \leq l \), \( V \in S_{B_j, B_j}^{k+1} \) and \( V \in S_{k, k+1} \), i.e. \( V \in S_A \). On the contrary:

\[
(f(v_1), f(v_2), \ldots, f(v_k), f(\bigwedge_{1 \leq j \leq k} v_j)) \notin S_{k, k+1}
\]

since the first \( k \) components of this vector are defined (the \( v_j \) are in the trace of \( f \)), and the last is \( \perp \) (\( \bigwedge v_i \) can’t be above \( v_j \)). Therefore, this tuple does not belong to \( S_A \).

It remains to show that that \( g \in S_A \). Let us suppose by reductio ad absurdum that there exists a matrix \( W = (w_1, \ldots, w_{k+1}) \in \mathcal{B}^{m \times (k+1)} \) such that:

\[
W \in S_A \text{ and } g(W) = (g(w_1), \ldots, g(w_{k+1})) \notin S_A
\]

First, we note that, since \( W \in S_A \), for all \( 1 \leq j \leq l \), \( W \in S_{B_j, B_j}^{k+1} \), that is \( \{w_i\}_{i \in B_j} \) is coherent, so \( \{g(w_i)\}_{i \in B_j} \) is coherent, and \( g \) is subsequential, which entails, by proposition 6 and lemma 12, that \( g(W) \) is invariant by \( S_{B_j, B_j}^{k+1} \). Therefore, \( g(W) \notin S_A \) means that \( g(W) \notin S_{k, k+1} \), that is, \( \forall j \leq k, g(w_j) \neq \perp \) and \( \exists j, j' \leq k+1, g(w_j) \neq g(w_{j'}) \). Since \( g \) is subsequential and \( \{w_1, \ldots, w_k\} \) is coherent (lemma 12), \( \forall j, j' \leq k, g(w_j) = g(w_{j'}) \): there exists \( b \in \{tt, ff\} \) such that

\[
\forall j \leq k, g(w_j) = b \text{ and } g(w_{k+1}) = \perp
\]

Hence any \( w_j \), for \( 1 \leq j \leq k \), has at least a lower bound in \( \pi_1(tr(g)) \), which we denote by \( z_j \). We have:

- the set \( \{z_1, \ldots, z_k\} \) is not a singleton, otherwise \( g(w_{k+1}) = b \), being \( w_{k+1} \geq \bigwedge_{1 \leq j \leq k} w_j \), by definition of \( S_{k, k+1} \).
- for all \( 1 \leq j \leq l \) the set \( \{z_i\}_{i \in B_j} \) is coherent, being an Egli-Milner lower bound of the coherent set \( \{w_i\}_{i \in B_j} \) (see fact 1).
- Last, by proposition 6, \( f \) being subsequential, \( C_{H_j} \) is constant on \( A \).

Hence the function \( \alpha : A \to H_g \) defined by \( \alpha_A(v_i) = z_i \) is in \( \mathcal{H}(H_{f|A}, \overline{P}_g) \), and it is not trivial, a contradiction.

Remark that, if \( g \) is subsequential and \( f \) is not, then \( f \not\leq_par g \), hence the hypothesis of Theorem 13 could be weakened.

In order to see that completeness of timed morphisms fails in general, let us consider the following monotone functions:

\[
\begin{cases}
  f(\perp, tt, tt, ff) = tt \\
  f(ff, \perp, tt, tt) = tt \\
  f(tt, ff, \perp, tt) = tt \\
  f(tt, tt, ff, \perp) = tt
\end{cases}
\]
\[
\begin{align*}
g(\bot, \top, \top) &= \top \\
g(\top, \bot, \top) &= \top \\
g(\top, \bot, \bot) &= \bot
\end{align*}
\]

Since all subsets of \( H_f \) with at least three elements are hyperarcs, and \( H_g \) is composed by a single ternary hyperarc, it is easy to see that there is no non trivial \( h \)-morphism from the maximal hyperarc of \( H_f \) to \( \overline{\mathcal{H}}_g \), and hence no timed morphism from \( H_f \) to \( H_g \). On the other hand \( f \leq_{\text{par}} g \), since the degree of \( g \) (the “B-K function”) is the top of stable degrees ([5], p. 334), and \( f \) is stable.

8 Conclusion

For a wide class of boolean functions (the subsequential ones) we are able to solve relative definability problems in a geometric way, using a suitable representation of functions as hypergraphs and PCF-terms as hypergraphs morphisms.

We can also list all the (sensible) terms solving a given problem \( f,g \), by enumerating the timed morphisms from \( H_f \) to \( H_g \), and choose, for instance, the one which uses as few calls of \( g \) as possible (but other notion of optimality could be considered).

A natural question is wether this approach can be extended to non subsequential boolean functions and/or to higher-order functions. We do not know at present, but probably a combination of more complex representations of functions as hypergraphs and of more involved notions of morphisms is required.

A Proof of the soundness theorem

First, we state a straightforward, yet useful, lemma:

**Lemma 14.** One can restrict a morphism $\alpha : H \to K$ to $B \subseteq V_H$ by $(\alpha|_B)_X = \alpha_X$ whenever $X$ is a hyperarc of $H|_B$. Moreover, if $\alpha$ is a timed morphism from $H_f$ to $H_g$, and $\text{tr}(f') \subseteq \text{tr}(f)$, $\alpha_{|\text{tr}(f')}^\text{tr}$ is a morphism from $H_f'$ to $H_g$.

Now we can proceed with the proof of the soundness theorem:

**Theorem 15.** Let $f : B^l \to B$, $g : B^m \to B$ be monotone functions such that $\text{TH}(H_f, H_g) \neq \emptyset$. Then $f \preceq \text{par} g$.

**Proof.** Let $\alpha \in \text{TH}(H_f, H_g)$. We prove the theorem by induction on $k = \#\text{tr}(f)$. If $k = 1$ $f$ is sequential, hence PCF-definable, and $f \preceq \text{par} g$ holds trivially. Suppose now $k = n + 1$; we reason by cases on the structure of $H_f$.

First, let us assume that $V_{H_f} \not\subseteq A_{H_f}$. This means that there exists an $1 \leq i \leq l$ such that $\pi(i) = \{\text{tt}, \text{ff}\}$. (i is a sequentiality index of $f$). Splitting the trace of $f$ in two subsets according to the value of this component, we define the functions $f_\text{tt}$ and $f_\text{ff}$.

For $\rho = \text{tt}, \text{ff}$, $\#\text{tr}(f_\rho) < \#\text{tr}(f)$. By lemma 14, there exists a timed morphism from $H_{f_\rho}$ to $H_g$. By inductive hypothesis, there exists $M_\rho g$-defining $f_\rho$.

Define:

$$M = \lambda g \lambda x. \text{if } x_i \text{ then } M_{\text{tt}} g x \text{ else } M_{\text{ff}} g x$$

It is easy to check that $M$ $g$-defines $f$.

Now, let us assume that $V = V_{H_f} \subseteq A_{H_f}$, $V_{H_f}$. Let $f_i, 1 \leq i \leq m$, be the $i$th-slice of $\alpha_V$, and define $\hat{f_i}$ as

$$\hat{f_i} = \begin{cases} f_i & \text{if } \#\text{tr}(f_i) < \#\text{tr}(f) \\ \lambda x. v & \text{for } v \in \pi_2(\text{tr}(f_i)) \text{ otherwise} \end{cases}$$

First, let us prove that the $\hat{f_i}$'s are well defined. If $\#\text{tr}(f_i) = \#\text{tr}(f)$ then $\pi_1(\text{tr}(f_i)) = \pi_1(\text{tr}(f))$. Since $V_{H_f}$ is a hyperarc of $H_f$, it is also a hyperarc of $H_{f_i}$. Since $f_i$ is subsequential, its hyperarcs are monochromatic. We get $\#\pi_2(\text{tr}(f_i)) = 1$. 

Let us prove that the \( \hat{f}_i \)'s are \( g \)-definable. The only case to be checked is \( \hat{f}_i = f_i \) in the previous definition, since \( \lambda x. v \) is PCF-definable. Since the \( f_i \)'s are subsequential, by lemma 7 \( f_i \leq_{par} f \), where \( \text{tr}(f_i) = \{ v \in \text{tr}(f) \mid \pi_1(v) \in \pi_1(\text{tr}(f_i)) \} \) (\( \text{tr}(f) \) is equal to \( f(x) \) whenever \( f_i(x) \neq \bot \), to \( \bot \) otherwise). Now \( \#\text{tr}(f_i) < \#\text{tr}(f) \), and, by lemma 14, \( \mathcal{H}(H) \neq \emptyset \). Hence by inductive hypothesis \( f_i \leq_{par} g \), and finally \( f_i \leq_{par} g \) by transitivity of \( \leq_{par} \). Let \( M_i \) be a term \( g \)-defining \( \hat{f}_i \).

Before constructing a term \( M \) \( g \)-defining \( f \) let us prove that we can already \( g \)-define a “convergence test” for \( f \), i.e. that for all \( x = (x_1, \ldots, x_l) \in B^l \):

\[
f(x) \neq \bot \iff g([M_1]gx, \ldots, [M_m]gx) \neq \bot
\]

The direction \( \Rightarrow \) is trivial, since the \( \hat{f}_i \)'s are upper bounds of the \( f_i \)'s, hence if there exists \( v \in \pi_1(\text{tr}(f)) \) such that \( v \leq x \), then \( ([M_1]gx, \ldots, [M_m]gx) \geq \alpha_V(v) \).

For the opposite direction, let us suppose that \( f(x) = \bot \), and hence for all \( v \in \pi_1(\text{tr}(f)) \), \( x \npreceq v \). By definition of the \( \hat{f}_i \)'s we know that for all \( w \in \alpha_V(V_{H_{f}}) \), \( ([M_1]gx, \ldots, [M_m]gx) \preceq w \), since, under the hypothesis \( f(x) = \bot \), we have that for all \( 1 \leq j \leq m \), if \( [M_j]gx = b > \bot \) then \( f_j = \lambda x. b \), and hence for all \( w \in \alpha(V_{H_{f}}) \), \( w_j = b \). Since \( V = V_{H_{f}} \) is a hyperarc, we know that \( \#\alpha_V(V) \geq 2 \), and by minimality of the elements of \( \pi_1(\text{tr}(g)) \) we conclude that for all \( w \in \pi_1(\text{tr}(g)) \) \( ([M_1]gx, \ldots, [M_m]gx) \npreceq w \), and hence \( g([M_1]gx, \ldots, [M_m]gx) = \bot \).

We can now conclude the proof, again by case reasoning on the structure of \( H_f \).

If \( V_{H_f} \) is a monochromatic hyperarc (w.l.o.g. assume that all vertices are white). Then it is easy to check that \( f \) is \( g \)-defined by the term:

\[
M = \lambda g \; \lambda x. \; \text{if } g(M_1gx) \ldots (M_mgx) \text{ then } \text{tt else } \text{tt}
\]

If \( V = V_{H_f} \) is not monochromatic, whenever \( C(x) = C(y) \), there exists \( z \in V_{H_f} \) such that \( C(z) \neq C(x) \) (resp. \( y \)). Then \( C(\alpha_V(z)) \neq C(\alpha_V(x)) \) (resp. \( y \)), which means:

\[
\forall x, y \in V_{H_f} \; C(x) = C(y) \iff C(\alpha_V(x)) = C(\alpha_V(y))
\]

i.e. \( \alpha_V \) acts as the identity or the “negation” on colors. We define then

\[
M = \lambda g \; \lambda x. \; \epsilon(g(M_1gx) \ldots (M_mgx))
\]

where \( \epsilon \) is the boolean identity or the boolean negation according to how \( \alpha_V \) acts on colors. Then again it is easily checked that \( M \) \( g \)-defines \( f \).
