Solving a Crop Problem by an Optimal Control Method

Hem Raj Joshi∗ Suzanne Lenhart∗ Maîtine Bergounioux†

(Draft)

Last Update : May 10th, 2004

Résumé

A system of ordinary differential equations coupled with a parabolic partial differential equation is studied in order to understand an interaction between two crops and a pathogen. Two different types of crops are planted in same field in some pattern so that the spread of pathogen can be controlled. The pathogen prefers to eat one crop. The other crop, which is not preferred by pathogen, is introduced to control the spread of pathogen in the farming land. The “optimal” initial planting pattern is sought to maximize plant yields while minimizing the variation in the planting pattern. The optimal pattern is characterized by a variation inequality involving the solutions of the optimality system. Numerical examples are given to illustrate the results.

Key Words : Crop Problem, Optimal Control, Pathogen Spread

1 Introduction

We consider a system with two ordinary differential equations (ODEs) and one parabolic partial differential equation (PDE) modeling the planting of two different types of crops \( u \) and \( v \) in same field in some pattern so that the spread of pathogen \( w \) can be controlled. The pathogen prefers to eat crop \( u \). The crop \( v \), which is not preferred by pathogen, is introduced to control the spread of pathogen in the farming land \( \Omega = (0,1) \).

The state system is the following:

\[
\begin{align*}
\frac{du}{dt} &= r_1 u (k_1 - u) - k_3 uw \\
\frac{dv}{dt} &= r_2 v (k_2 - v) - k_4 vw \\
w_t &= d_1 w_{xx} + \alpha_1 k_3 uw + \alpha_2 k_4 vw - \mu w
\end{align*}
\]

with initial and boundary conditions:

\[
\begin{align*}
u(x,0) &= u_0(x), & v(x,0) &= v_0(x) = a - u_0(x) & w(x,0) &= w_0(x) \quad \text{for } x \in \Omega \\
w(0,t) &= 0 = w(1,t) \quad \text{on } \partial \Omega \times (0,T).
\end{align*}
\]

The coefficients and terms can be interpreted as:

- \( u(x,t) \) = crop preferred by pathogen (first state variable).
- \( v(x,t) \) = crop not preferred by pathogen (second state variable).
- \( w(x,t) \) = pathogen (third state variable).
- \( r_1, r_2 \) = growth rates.
- \( d_1 \) = diffusion coefficient.
- \( k_1, k_2 \) = the carrying capacities.
- \( \alpha_1, \alpha_2, k_3, k_4 \) = interaction coefficients.
- \( \mu \) = pathogen natural death rate.

The control set is

\[
U = \{ u_0(x) \in H^1_0(0,1) | 0 \leq u_0(x) \leq a \}
\]

We seek to maximize the objective functional over \( u_0 \in U \):

\[
J(u_0) = \int_0^1 \left[ (A_1 u + A_2 v)(x,T) - \frac{1}{2} (u_0')^2 + B_1 u_0^2 + B_2 (a - u_0)^2 \right] \, dx.
\] (1.1)

The positive constants \( A_1 \) and \( A_2 \) represent the relative importance of the terms \( u \) and \( v \) respectively and \( B_1 \) and \( B_2 \) are multipliers of the cost of implementing the control. Minimizing the \( u_0' \) term represents low variation in \( u_0 \). A planting pattern with high
variation would be unrealistic to implement. The goal would be to maximize plant yields (subject to relative importance of the two crops) while minimizing the variation in the initial planting pattern.

Intercropping for weed and pest management has been considered in a variety of contexts [5, 8, 9], but mostly in the setting of systems of ODEs differential equations or difference equations. Here we have a combination of a parabolic PDE for diffusion of the pathogen with ODEs for the crops. Due to inclusion of the $u'$ variation term in the objective functional, our characterization of the optimal planting pattern is a variational inequality [7], instead of simply an algebraic expression in terms of the state and adjoint variables. Such a variational inequality is somewhat novel in control of PDE problems and requires an unusual numerical algorithm.

In section 2, we discuss the existence of an optimal control, i.e. the optimal planting pattern. The optimality system, which characterizes the optimal control, is derived in section 3. The optimality system involves the state system and the adjoint system together with the characterization of the optimal control given by a variational inequality. Section 4 treats the uniqueness of the optimal control by obtaining the uniqueness of the solutions of the optimality system for $T$ sufficiently small. Finally in section 5, we discuss our numerical algorithm and illustrate numerical examples for our problem.

2 Existence of an Optimal Control

The following assumptions are made throughout this paper.

1. $\alpha_2 k_4 < \mu$
2. $r_1, r_2, d_1, k_3, k_4, \alpha_1, \alpha_2, \mu$ are positive constants and $\alpha_1 k_3 > \alpha_2 k_4$.
3. $0 < a \leq 1$.

Assumption 1 means that the $u \equiv 0$ would cause the pathogen to decay when it only eats the second crop. Assumption 2 means that the consumption of crop $u$ contributes more to the growth of the pathogen than would consumption of crop $v$.

The underlying solution space for system (1.1) is $V = (L^2(Q))^2 \times L^2(0,T;H^1_0(\Omega))$.

Definition 2.1 We say a triple of functions $u, v, w \in V$, with $w_t \in L^2(0,T;H^{-1}(\Omega))$, is a weak solution of (1.1) with given boundary and initial conditions provided

\[
\begin{align*}
  u(x,t) &= u_0(x) + \int_0^T [r_1 u(k_1 - u) - k_3 u w](x,s) \, ds \\
  v(x,t) &= v_0(x) + \int_0^T [r_2 v(k_2 - v) - k_4 v w](x,s) \, ds \\
  \int_0^T <w_t, \phi> \, dt + d_1 \int_Q \nabla u \nabla \phi \, dx \, dt
\end{align*}
\]
\[ = \int_Q \left( \alpha_1 k_3 uw + \alpha_2 k_4 vw - \mu w \right) \phi \, dx \, dt \]

for all \( \phi \in L^2(0,T;H^1_0(\Omega)) \), where the \( < , > \) inner product is the duality between \( H^{-1}(\Omega) \) and \( H^1_0(\Omega) \), and

\[ u(x,0) = u_0(x), \quad v(x,0) = v_0(x) \quad w(x,0) = w_0(x), \quad w(0,t) = 0 = w(1,t) \quad (2.1) \]

**Remark** : Since \( u, v \in C(0,T;L^2(\Omega)) \) from Evans [1], the initial conditions (2.1) make sense.

We will prove an existence and uniqueness result for the state system (1.1). This result will be established in Theorem 2.1.

**Theorem 2.1** Given \( u_0 \in U \), there exists a unique solution \((u,v,w)\) in \( V \) solving (1.1) and (2.1).

**Proof** : We consider the following problems

\[
\begin{align*}
\frac{dU}{dt} &= r_1 k_1 U \\
U(x,0) &= u_0(x) \quad \text{for } x \in \Omega \\
\frac{dV}{dt} &= r_2 k_2 V \\
V(x,0) &= v_0(x) \quad \text{for } x \in \Omega \\
W_t &= d_1 W_{xx} + \alpha_1 k_3 UW + \alpha_2 k_4 VW - \mu W \\
W(x,0) &= w_0(x) \quad \text{for } x \in \Omega \\
W(0,t) &= W(1,t) \quad \text{on } \partial \Omega \times (0,T). 
\end{align*}
\]

The functions \( U, V, W \) are supersolutions of system equations in (1.1), which are \( L^\infty \) bounded in \( Q \). To obtain the existence, we will construct three sequences by means of iteration, using the above supersolutions.

Define : \( u^1 = U, v^1 = V, w^2 = W, u^0 = 0, v^0 = 0, w^1 = 0 \), where the superscripts denote the iteration step. For \( i = 2, 3, \cdots \), we define \( u^i, v^i \) and \( w^{i+1} \) as the solution of the following problems respectively :

\[
\begin{align*}
u^i_t + Ru^i &= f(u^{i-2}, v^i) \quad \text{in } Q \\
u^i(x,0) &= u_0(x) \quad \text{for } x \in \Omega \\
v^i_t + Rv^i &= g(v^{i-2}, w^i) \quad \text{in } Q \\
v^i(x,0) &= v_0(x) \quad \text{for } x \in \Omega \\
w^i_t - d_1 w^i_{xx} + Rw^i &= h(u^{i-1}, v^{i-1}, w^{i-2}) \quad \text{in } Q \\
w^i(x,0) &= w_0(x) \quad \text{for } x \in \Omega \\
w^i(0,t) &= 0 = w^i(1,t) \quad \text{on } \partial \Omega \times (0,T). 
\end{align*}
\]
where \( f(u^{i-2}, v^i) = Ru^{i-2} + r_1 u^{i-2} (k_1 - u^{i-2}) - k_3 u^{i-2} v^i \)
\( g(v^{i-2}, w^i) = Rv^{i-2} + r_2 v^{i-2} \),
\( h(u^{i-1}, v^{i-1}, w^{i-2}) = Ru^{i-2} + \alpha_1 k_3 u^{i-1} w^{i-2} + \alpha_2 k_4 v^{i-1} w^{i-2} - \mu w^{i-2} \).

\( R \) is a constant satisfying \( \sup_Q ((k_3 + k_4 + \mu) W + 2r_1 U + 2r_2 V) \).

Since (2.2)(2.2) and (2.2) are linear problems, the solutions \( u^i, v^i, w^i \), for \( i = 1, 2, \cdots \), exist.

**Claim 1**:

For \( i = 1, 2, \cdots, 0 \leq u^i \leq U, 0 \leq v^i \leq V, 0 \leq w^i \leq W \) in \( Q \).

Claim 1 can be proved by induction using the maximum principle.

Note that for \( u^i \geq 0, v^i \geq 0, w^i \geq 0, i = 1, 2, \cdots, \)
\( f \) is increasing in \( u^{i-2} \), and decreasing in \( v^i \).
\( g \) is increasing in \( v^{i-2} \), and decreasing in \( w^i \).
\( h \) is increasing in \( u^{i-1}, v^{i-1} \) and decreasing in \( w^{i-2} \).

**Claim 2**:

There exists \( \overline{u}, \overline{v}, \overline{w}, u, v, w \) in \( V \) such that the following monotone pointwise convergence holds.

\[
\begin{align*}
&u^{2i} \nearrow \overline{u}, &u^{2i+1} \searrow u &\text{ in } Q \\
v^{2i} \nearrow \overline{v}, &v^{2i+1} \searrow v &\text{ in } Q \\
w^{2i} \searrow \overline{w}, &w^{2i+1} \nearrow w &\text{ in } Q.
\end{align*}
\]

**Proof of Claim 2**:

To prove the convergence we use the induction method. Since \( u^1 = 0 \), we have
\[
(w^5 - w^3)_t - d_1(w^5 - w^3)_{xx} + R(w^5 - w^3) = w^3 (R + \alpha_1 k_3 u^4 + \alpha_2 k_4 v^4 - \mu) \geq 0
\]
and thus \( 0 \leq w^1 \leq w^3 \leq w^5 \). Similarly we have \( u^3 \leq u^1, v^3 \leq v^1, w^2 \geq w^4, u^0 \leq u^2 \) and \( v^0 \leq v^2 \). Also \( u^2 \leq u^3, v^2 \leq v^3 \) and \( w^4 \geq w^3 \) since
\[
\begin{align*}
(u^2 - u^3)_t + R(u^2 - u^3) &= -u^1 (R + r_1 (k_1 - u^1) - k_3 w^3) \leq 0 \\
(v^2 - v^3)_t + R(v^2 - v^3) &= -v^1 (R + r_2 (k_2 - v^1) - k_4 w^3) \leq 0 \\
(w^4 - w^3)_t - d_1(w^4 - w^3)_{xx} + R(w^4 - w^3) &= w^2 (R + \alpha_1 k_3 u^3 + \alpha_2 k_4 v^3 - \mu) \geq 0.
\end{align*}
\]

Fix \( i \), assume that for all \( j < i - 1 \) such that
\[
\begin{align*}
u^{2j} &\nearrow \overline{u}, &u^{2j+1} &\searrow u, \\
v^{2j} &\nearrow \overline{v}, &v^{2j+1} &\searrow v, \\
w^{2j} &\searrow \overline{w}, &w^{2j+1} &\nearrow w.
\end{align*}
\]
Now we compare $w^{2i+1}$ and $w^{2i}$. From (2.2), we have
\[
(w^{2i+2} - w^{2i})_t - d_1(w^{2i+2} - w^{2i})_{xx} + R(u^{2i+2} - w^{2i})
= h(u^{2i+1}, v^{2i+1}, w^{2i}) - h(u^{2i-1}, v^{2i-1}, w^{2i-2}) \leq 0.
\]
Then $w^{2i+2} \leq w^{2i}$. Other cases can be proved using similar arguments. Hence by boundedness of $u^i, v^i, w^i$ and monotone properties of $f, g, h$, we get the pointwise convergence.

**Claim 3:**

The subsequences of $\{u^i\}, \{v^i\}, \{w^i\}$ satisfy:
\[
u^{2j} \rightarrow \bar{u}, \quad u^{2j+1} \rightarrow \bar{u}, \quad v^{2j} \rightarrow \bar{v}, \quad v^{2j+1} \rightarrow v, \quad w^{2j} \rightarrow \bar{w}, \quad w^{2j+1} \rightarrow w \quad \text{weakly in } V.
\]

**Proof of Claim 3:**

Since RHS of (2.2), (2.2) and (2.2) are bounded in $L^\infty(Q)$, then the sequences
\[
\{(u^{2i}, v^{2i}, w^{2i})\}, \{(u^{2i+1}, v^{2i+1}, w^{2i+1})\}
\]
are uniformly bounded in $V$.

Hence using the weak compactness of the sequences in $V$, we get
\[
u^{2j} \rightarrow \bar{u}, \quad u^{2j+1} \rightarrow \bar{u}, \quad v^{2j} \rightarrow \bar{v}, \quad v^{2j+1} \rightarrow v, \quad w^{2j} \rightarrow \bar{w}, \quad w^{2j+1} \rightarrow w \quad \text{weakly in } V.
\]

Since we have pointwise convergence on each sequence by claim 2, this weak convergence is also on the whole (even or odd) sequence (not just on a subsequence).

**Claim 4:**

The subsequences of $\{u^i\}, \{v^i\}, \{w^i\}$ satisfy
\[
u^{2j} \rightarrow \bar{u}, \quad u^{2j+1} \rightarrow \bar{u}, \quad v^{2j} \rightarrow \bar{v}, \quad v^{2j+1} \rightarrow v, \quad w^{2j} \rightarrow \bar{w}, \quad w^{2j+1} \rightarrow w \quad \text{strongly in } L^2(Q).
\]

**Proof of Claim 4:**

Using the $V$ boundedness on $u^{2i}, u^{2i+1}, v^{2i}, v^{2i+1}, w^{2i}, w^{2i+1}$ and the system in (2.2)–(2.2), we obtain that
\[
\|u^{2i}_t\|, \|u^{2i+1}_t\| \text{ are bounded in } L^2(0, T; H^{-1}(\Omega)).
\]

Hence, using weak compactness again, we have
\[
u^{2i}_t \rightarrow \bar{u}_t, \quad u^{2i+1}_t \rightarrow \bar{u}_t \quad \text{weakly in } L^2(0, T; H^{-1}(\Omega)).
\]

Using a compactness result by Simon [10] for $w$ and, we have
\[
w^{2i} \rightarrow \bar{w}, \quad w^{2i+1} \rightarrow w \quad \text{strongly in } L^2(Q).
\]
Since equations (2.2), (2.2) are ODEs in time with parameters \(x\) and bounded RHS, the sequence is uniformly Lipschitz in \(t\) for each \(x\), we can pass to limit in \(u, v\) by using weak solution definition

\[
u^{2i} \to \overline{u}, \quad \nu^{2i+1} \to u, \quad \nu^{2i} \to \overline{v}, \quad \nu^{2i+1} \to v
\] pointwise uniformly in \(t\), for each \(x\)

Now we prove the uniqueness, i.e., \(u = \overline{u}, v = \overline{v}\) and \(w = \overline{w}\). Passing to the limit in the \(u^{2i}, u^{2i+1}, v^{2i}, v^{2i+1}, w^{2i}\), and \(w^{2i+1}\) PDE’s, we obtain:

\[
\begin{align*}
    \overline{u}_t &= r_1 k_1 \overline{u} - r_1 u^2 - k_3 \overline{w} \quad \text{in } Q \\
    \overline{u}(x, 0) &= u_0(x) \quad \text{for } x \in \Omega \\
    \overline{u}_t &= r_1 k_1 u - r_1 u^2 - k_3 u w \quad \text{in } Q \\
    \overline{u}(x, 0) &= u_0(x) \quad \text{for } x \in \Omega \\
    \overline{v}_t &= r_2 k_2 \overline{v} - r_2 v^2 - k_4 \overline{w} \quad \text{in } Q \\
    \overline{v}(x, 0) &= v_0(x) \quad \text{for } x \in \Omega \\
    \overline{v}_t &= r_2 k_2 v - r_2 v^2 - k_4 v w \quad \text{in } Q \\
    \overline{v}(x, 0) &= v_0(x) \quad \text{for } x \in \Omega
\end{align*}
\]

\[
\begin{align*}
    \overline{w}_t - d_1 \overline{w}_{xx} &= \alpha_1 k_3 u \overline{w} + \alpha_2 k_3 v \overline{w} - \mu \overline{w} \quad \text{in } Q \\
    \overline{w}(0, t) &= 0 = \overline{w}(1, t) \quad \text{on } \partial \Omega \times (0, T) \\
    \overline{w}(x, 0) &= w_0(x) \quad \text{for } x \in \Omega \\
    \overline{w}_t - d_1 \overline{w}_{xx} &= \alpha_1 k_3 w + \alpha_2 k_3 \overline{w} - \mu w \quad \text{in } Q \\
    \overline{w}(0, t) &= 0 = w(1, t) \quad \text{on } \partial \Omega \times (0, T) \\
    \overline{w}(x, 0) &= w_0(x) \quad \text{for } x \in \Omega
\end{align*}
\]

Let \(u = e^{\lambda t} f, \overline{u} = e^{\lambda t} \overline{f}, v = e^{\lambda t} g, \overline{v} = e^{\lambda t} \overline{g}, w = e^{\lambda t} h\) and \(\overline{w} = e^{\lambda t} \overline{h}\), where \(\lambda > 0\) is to be chosen. To illustrate the transformed system, we write equation (2.2):

\[
f_t + \lambda f = r_1 k_1 f - r_1 e^{\lambda t} f^2 - k_3 e^{\lambda t} fh \quad \text{in } Q
\]

We consider the weak formulation of the \(f - \overline{f}, g - \overline{g}\) and \(h - \overline{h}\) problems, and after adding both weak formulations, we obtain on \(Q_1 = \Omega \times (0, t_1)\):

\[
\begin{align*}
    &\int_{Q_1} \{(f - \overline{f})_t (f - \overline{f}) + \lambda(f - \overline{f})^2 + (g - \overline{g})_t (g - \overline{g}) + \lambda(g - \overline{g})^2 \} \, dx \, dt \\
    &+ \int_{Q_1} \{(h - \overline{h})_t (h - \overline{h}) + d_1 |\nabla (h - \overline{h})|^2 + \lambda(h - \overline{h})^2 \} \, dx \, dt \\
    = &\int_{Q_1} \{r_1 k_1(f - \overline{f})^2 - r_1 e^{\lambda t} (f^2 - \overline{f}^2) (f - \overline{f}) - k_3 e^{\lambda t} f (f - \overline{f}) (fh - f \overline{h}) \} \, dx \, dt \\
    &+ \int_{Q_1} \{r_2 k_2(g - \overline{g})^2 - r_2 e^{\lambda t} (g^2 - \overline{g}^2) (g - \overline{g}) - k_4 e^{\lambda t} (g - \overline{g}) (gh - \overline{g} \overline{h}) \} \, dx \, dt \\
    &+ \int_{Q_1} \{\alpha_1 k_3(\overline{f} h - f \overline{h})(h - \overline{h}) + \alpha_2 k_4 (\overline{g} h - g \overline{h})(h - \overline{h}) - \mu (h - \overline{h})^2 \} \, dx \, dt.
\end{align*}
\]
We obtain
\[ \frac{1}{2} \int_{\Omega} \left\{ |f - \bar{f}|^2(x, T) + |g - \bar{g}|^2(x, T) + |h - \bar{h}|^2(x, T) \right\} \, dx + \int_{Q_1} \left\{ [d_1(|\nabla (h - \bar{h})|)]^2 \right\} \, dx \, dt + (\lambda - C_1 - C_2 e^{\lambda t}) \int_{Q_1} [(f - \bar{f})^2 + (g - \bar{g})^2 + (h - \bar{h})^2] \, dx \, dt \leq 0 \]

where \( C_1, C_2 \) depend on the coefficients and the solution bounds.

If we choose \( \lambda > C_1 + C_2 \) and \( t_1 \) such that \( t_1 < \frac{1}{\lambda} \ln \left( \frac{\lambda - C_1}{C_2} \right) \), then inequality (2.9) holds if and only if
\[
\begin{align*}
  f &= \bar{f}, \quad g = \bar{g}, \quad w = \bar{w} \quad \text{a.e. in} \ Q.
\end{align*}
\]

Similarly the proof can be completed for time intervals \(((t_1, 2t_1], [2t_1, 3t_1] \ldots)\). Therefore, \( u = \bar{u}, \ v = \bar{v} \) and \( v = \bar{v} \) a.e. in \( Q \), and \( u, v, w \) solve the state system (1.1). Hence the solution to the state system (1.1) exists and the uniqueness of \( u, v, w \) as solutions of (1.1) follows similarly as in the above argument.

**Theorem 2.2** There exists an optimal control in \( U \) that maximizes the functional \( J(u_0) \).

**Proof**: \( \sup\{ J(u_0) | u_0 \in U \} < \infty \) since the state variables and controls are uniformly bounded. Thus there exists a maximizing sequence \( u_0 \in U \) such that
\[
\lim_{n \to \infty} J(u_{0}^{n}) = \sup \{ J(u_0) | u_0 \in U \}.
\]

By the existence and uniqueness of solutions to the state system (1.1), we define
\[
u^n = u(u_0^n), \quad v^n = v(u_0^n), \quad w^n = w(u_0^n) \quad \text{for each} \ n.
\]

On a subsequence, as \( n \to \infty \), \( u_0^n \to u_0^* \) in \( L^2(Q) \) and \( (u_0^n)' \to (u_0^*)' \) weakly in \( L^2(Q) \)

Passing to the limit in the \( u^n, v^n, w^n \) system and using the convergences as in Theorem 2.1, we have that \( (u, v, w) \) is weak solution of (1.1) associated with \( u_0^* \). Since the payoff functional is upper semi-continuous with respect to the weak convergence, we have
\[
J(u_0^*) \leq \sup \{ J(u_0^n) | u_0^n \in U \}.
\]

Therefore \( u_0^* \) is an optimal control that maximizes the payoff functional.

### 3 Derivation of the Optimality System

We now derive the optimality system which consists of the state system coupled with the adjoint system. In order to obtain the necessary conditions for the optimality system
we differentiate the objective functional with respect to the control. As our objective functional also depends on state variables, we differentiate the state variables with respect to the control $u_0$

**Theorem 3.1** The mapping $u_0 \in U \rightarrow (u,v,w) \in V$ is differentiable in the following sense:

$$
\begin{align*}
\frac{u(u_0 + \epsilon) - u(u_0)}{\epsilon} & \rightharpoonup \psi_1 \text{ weakly in } L^2(Q) \\
\frac{v(u_0 + \epsilon) - v(u_0)}{\epsilon} & \rightharpoonup \psi_2 \text{ weakly in } L^2(Q) \\
\frac{w(u_0 + \epsilon) - w(u_0)}{\epsilon} & \rightharpoonup \psi_3 \text{ weakly in } L^2(0,T;H^1_0(\Omega))
\end{align*}
$$

as $\epsilon \to 0$ for any $u_0 \in U$ and $l \in L^\infty(Q)$ s.t. $(u_0 + \epsilon) \in U$ for $\epsilon$ small. Also $\psi_1, \psi_2, \psi_3$ (depending on $u,v,w,u_0,l$) satisfy the following system:

$$(\psi_1)_t = r_1(k_1 - 2u_0)\psi_1 - k_3(u\psi_3 + w\psi_1) \quad \text{in } Q$$

$$(\psi_2)_t = r_2(k_2 - 2v_0)\psi_2 - k_4(v\psi_3 + w\psi_2) \quad \text{in } Q$$

$$(\psi_3)_t = d_1(\psi_3)_{xx} + \alpha_1 k_3(u\psi_3 + w\psi_1) + \alpha_2 k_4(v\psi_3 + w\psi_2) - \mu \psi_3 \quad \text{in } Q$$

$$(\psi_1(x,0) = l, \quad (\psi_2(x,0) = -l, \quad (\psi_3(x,0) = 0 \quad \text{for } x \in \Omega)$$

$$\psi_3(0,t) = 0 = \psi_3(1,t) \quad \text{on } \partial \Omega \times (0,T)$$

**Proof**: Define $u^\epsilon = u(u_0 + \epsilon), v^\epsilon = v(u_0 + \epsilon), u = u(u_0), v = v(u_0)$ and $w = w(u_0)$. We do a change of variables: $u^\epsilon = e^\lambda f^\epsilon, u = e^\lambda f, v^\epsilon = e^\lambda g^\epsilon, v = e^\lambda g, w^\epsilon = e^\lambda h^\epsilon, w = e^\lambda h$, where $\lambda > 0$ is to be chosen below.

On the set $Q_1 = \Omega \times (0,t_1)$ for $0 < t_1 \leq T$, we illustrate the “$h$” equation:

$$
\int_{Q_1} \left[ \left( \frac{h^\epsilon - h}{\epsilon} \right)_t + \lambda \left( \frac{h^\epsilon - h}{\epsilon} \right)^2 + d_1 \left| \left( \frac{h^\epsilon - h}{\epsilon} \right)_x \right|^2 \right] dx \ dt
$$

$$
= \int_{Q_1} \left[ \alpha_1 k_3 e^{\lambda t} \left( \frac{f^\epsilon}{\epsilon} \frac{h^\epsilon - h}{\epsilon} \right) + h \left( \frac{f^\epsilon - f}{\epsilon} \right) \left( \frac{h^\epsilon - h}{\epsilon} \right) \right] dx \ dt
$$

Continuing to estimate using $L^\infty$ bounds on the coefficients and $f,g,h,f^\epsilon,g^\epsilon$ and $h^\epsilon$, we have

$$
\frac{1}{2} \int_{\Omega \times \{t_1\}} \left[ \left( \frac{f^\epsilon - f}{\epsilon} \right)^2 + \left( \frac{g^\epsilon - g}{\epsilon} \right)^2 + \left( \frac{h^\epsilon - h}{\epsilon} \right)^2 \right] dx + \int_{Q_1} d_1 \left| \left( \frac{h^\epsilon - h}{\epsilon} \right)_x \right|^2 dx \ dt
$$

$$
+ \left( \lambda - (C_1 + C_2 e^{\lambda t_1}) \right) \int_{Q_1} \left[ \left( \frac{f^\epsilon - f}{\epsilon} \right)^2 + \left( \frac{g^\epsilon - g}{\epsilon} \right)^2 + \left( \frac{h^\epsilon - h}{\epsilon} \right)^2 \right] dx \ dt
$$

$$
\leq C \int_{\Omega} t^2 dx.
$$
For $\lambda > C_1 + C_2$ and $t_1$ small such that $t_1 < \frac{1}{\lambda} \ln \frac{\lambda - C_1}{C_2}$, we conclude
\[
\left\| \frac{f^\epsilon - f}{\epsilon} \right\|_{L^2(Q_1)}^2 + \left\| \frac{g^\epsilon - g}{\epsilon} \right\|_{L^2(Q_1)}^2 + \left\| \frac{h^\epsilon - h}{\epsilon} \right\|_{L^2(0,t_1;H^1_0(\Omega))}^2 \leq C \int_\Omega l^2 \, dx.
\]
Similarly this estimate can be carried out on intervals $[t_1, 2t_1], [2t_1, 3t_1], \ldots$ and the estimate finally holds on $[0, T]$. This estimate justifies the convergence of $f, g$ and $h$ quotients, and hence
\[
\frac{u^\epsilon - u}{\epsilon} \rightharpoonup \psi_1 \quad \text{weakly in } L^2(Q)
\]
\[
\frac{v^\epsilon - v}{\epsilon} \rightharpoonup \psi_2 \quad \text{weakly in } L^2(Q)
\]
\[
\frac{w^\epsilon - w}{\epsilon} \rightharpoonup \psi_3 \quad \text{weakly in } L^2(0,T; H^1_0(\Omega))
\]
Similarly we obtain
\[
\left( \frac{w^\epsilon - w}{\epsilon} \right)_t \rightharpoonup (\psi_3)_t \quad \text{weakly in } L^2(0,T; H^{-1}(\Omega))
\]
and
\[
\frac{w^\epsilon - w}{\epsilon} \rightarrow \psi_3, \quad \text{strongly in } L^2(Q)
\]
\[
\frac{u^\epsilon - u}{\epsilon}, \frac{v^\epsilon - v}{\epsilon} \quad \text{are uniformly Lipschitz in } t \text{ for each } x.
\]
These convergences also give $u^\epsilon \rightarrow u$, $v^\epsilon \rightarrow v$, $w^\epsilon \rightarrow w$ strongly in $L^2(Q)$.

To see the system satisfied by $\psi_1, \psi_2, \psi_3$, consider terms from the system satisfied by $\frac{u^\epsilon - u}{\epsilon}, \frac{v^\epsilon - v}{\epsilon}$ and $\frac{w^\epsilon - w}{\epsilon}$; for example
\[
\frac{1}{r_1} r_1 \left( (u^\epsilon)^2 - u^2 \right) = r_1 \frac{1}{r_1} (u^\epsilon - u)(u^\epsilon + u) \rightarrow 2r_1 u \psi_1 \quad \text{as } \epsilon \rightarrow 0,
\]
\[
\frac{1}{k_3} k_3 (u^\epsilon w^\epsilon - uw) = k_3 \frac{1}{k_3} (u^\epsilon (w^\epsilon - w) + w(u^\epsilon - u)) \rightarrow k_3 (w \psi_3 + w \psi_1),
\]
since $u^\epsilon \rightarrow u$, $w^\epsilon \rightarrow w$ as $\epsilon \rightarrow 0$.

The above estimates justify passing the limit in the system satisfied by $\frac{u^\epsilon - u}{\epsilon}, \frac{v^\epsilon - v}{\epsilon}$ and $\frac{w^\epsilon - w}{\epsilon}$, and we conclude that $\psi_1, \psi_2, \psi_3$ solves (3.1).

To derive the optimality system and to characterize the pairs of optimal controls, we need adjoints and adjoints of the operators associated with $\psi_1, \psi_2, \psi_3$ system as
\[
\mathcal{L} \begin{pmatrix}
\psi_1 \\
\psi_2 \\
\psi_3
\end{pmatrix} = \begin{pmatrix}
0 \\
0 \\
0
\end{pmatrix},
\]
Given an optimal control

Theorem 3.2 Existence of Weak Solution

if for all \( v \)
where

Definition 3.1

We define the adjoint PDE system as

where

with

and \( M^\tau \) is the transpose of matrix \( M \). Note that \( A_1, A_2 \) from the objective functional will occur as final time values for \( p, q \).

To clarify the characterization of our optimal control, we make the following definition involving a variational inequality with upper and lower obstacles [3] :

**Definition 3.1** \( u_0 \in U \) is a weak solution of the following bilateral variational inequality

\[
\min \{ \max \{ -p(x,0) - q(x,0) + (u_0)_{xx} - B_1 u_0 + B_2 (a - u_0), u_0 - a \}, u_0 - 0 \} = 0
\]

if for all \( v_0 \in U \),

\[
\int_{\Omega} [(u_0)_x(v_0 - u_0)_x + (q(x,0) - p(x,0) + B_1 u_0 - B_2 (a - u_0)) (v_0 - u_0)] \, dx \geq 0.
\]

**Theorem 3.2** Existence of Weak Solution

Given an optimal control \( u_0 \) and corresponding solution \( (u, v, w) = (u(u_0), v(u_0), w(u_0)) \)
there exists a weak solution \((p,q,r) \in (L^{2}(Q))^{2} \times L^{2}(0,T; H_{0}^{1}(\Omega))\) satisfying the adjoint system:

\[
\begin{align*}
\mathcal{L}^{*}_{1}p &= (r_{1}(k_{1} - 2u) - k_{3}w)p + \alpha_{1}k_{3}wr \\
\mathcal{L}^{*}_{2}q &= (r_{2}(k_{2} - 2v) - k_{4}w)q + \alpha_{2}k_{4}wr \\
\mathcal{L}^{*}_{3}r &= -k_{3}up - k_{4}vq + (\alpha_{1}k_{3}u + \alpha_{2}k_{4}v - \mu)r
\end{align*}
\]

and transversality conditions

\[
p(x,T) = A_{1}, \quad q(x,T) = A_{2}, \quad r(x,T) = 0 \quad \text{where } x \in \Omega
\]
\[
r(0,t) = 0 = r(1,t) \quad \text{where } t \in [0,T].
\]

And furthermore \(u_0(x)\) must satisfy the following variational inequality in the weak sense.

\[
\min \left\{ \max \left( - (p(x,0) - q(x,0)) + (u_0)_{xx} - B_1u_0 + B_2(a - u_0) \right), u_0 - a, u_0 - 0 \right\} = 0
\]

**Proof:** Let \(u_0(x)\) be an optimal control (which exists by Theorem 2.2) and \((u,v,w)\) be its corresponding state solution. Let \((u_0(x) + \epsilon l) \in U\) for \(\epsilon > 0\), and \(u^\epsilon, v^\epsilon, w^\epsilon\) be the corresponding weak solution of state system (1.1). Since the adjoint equations are linear, there exists a weak solution \(p,q,r\) satisfying (3.2 - 3.2). We compute the directional derivative of the objective functional \(J(u_0)\) with respect to \(u_0\) in the direction \(l\) at \(u_0\). Since \(J(u_0)\) is the maximum value, we have

\[
0 \geq \lim_{\epsilon \to 0^+} \frac{J(u_0(x) + \epsilon l) - J(u_0)}{\epsilon}
\]

\[
= \lim_{\epsilon \to 0^+} \left\{ \int_{0}^{1} \left[ A_{1} \left( \frac{u_{x}}{\epsilon} \right) + A_{2} \left( \frac{v_{x}}{\epsilon} \right) \right] (x,T) \, dx - \frac{1}{2} \int_{0}^{1} \left[ B_{1} \left( \frac{u_{xx}}{\epsilon} \right)^{2} - (u_0)_{xx}^{2} \right] \, dx \right. \\
- \frac{1}{2} \int_{0}^{1} \left[ B_{2} \left( \frac{u_{xx}}{\epsilon} \right)^{2} - (a - u_0)^{2} \right] \, dx \right\}
\]

\[
= \int_{0}^{1} \left[ (p\psi_1 + q\psi_2)(x,T) - (u_0)_{xx} - B_1u_0 + B_2(a - u_0) \right] \, dx
\]

\[
= \int_{0}^{1} \left[ (p\psi_1 + q\psi_2)(x,T) - (u_0)_{xx} - B_1u_0 + B_2(a - u_0) \right] \, dx
\]

\[
+ \int_{0}^{T} \int_{0}^{1} \left[ p\psi_1 + q\psi_2 \right] \left( r_{1}(k_{1} - 2u) - k_{3}w \right) \psi_1 \, dx \, dt
\]

\[
+ \int_{0}^{T} \int_{0}^{1} \left[ p\psi_1 + q\psi_2 \right] \left( r_{2}(k_{2} - 2v) - k_{4}w \right) \psi_2 \, dx \, dt
\]

\[
+ \int_{0}^{T} \int_{0}^{1} \left[ r\psi_3 + 1 \right] \left( k_{3}u - k_{4}v + (\alpha_{1}k_{3}u + \alpha_{2}k_{4}v - \mu) \right) \psi_3 \, dx \, dt
\]

\[
= \int_{0}^{1} \left[ (p\psi_1 + q\psi_2)(x,0) - (u_0)_{xx} - B_1u_0 + B_2(a - u_0) \right] \, dx + \int_{0}^{T} \int_{0}^{1} \mathcal{L} \left( \begin{array}{c} 
\psi_1 \\
\psi_2 \\
\psi_3 
\end{array} \right) \, dx \, dt
\]

\[
= \int_{0}^{1} \left[ p(x,0) - lq(x,0) - (u_0)_{xx} - B_1u_0 + B_2(a - u_0) \right] \, dx
\]
Theorem 4.1

4 Uniqueness of the Optimality System

Involving parabolic PDEs; see the uniqueness results in optimal control of the PDE/ODE system. Note that such a small parameter characterization (3.2) of the unique optimal control in terms of the solutions of the optimality system is unique.

We now prove the uniqueness of weak solutions of optimality system, which gives the characterization (3.2) of the unique optimal control in terms of the solutions of the optimality system. Note that such a small parameter restriction is common in optimal control problems involving parabolic PDEs; see the uniqueness results in optimal control of the PDE/ODE systems in [2, 6].

4 Uniqueness of the Optimality System

Theorem 4.1 For $T$ sufficiently small and $B_1 + B_2$ sufficiently large, weak solutions of the optimality system are unique.
Proof: Suppose \( u, v, p, q, r, u_0 \) and \( \overline{u}, \overline{v}, \overline{p}, \overline{q}, \overline{w}_0 \) are two solutions of the optimal system (3.2). We change the variables for \( \lambda > 0 \) to be chosen such that

\[
\begin{align*}
&u = e^{\lambda t} u_1, \quad \overline{u} = e^{\lambda T} u_2 \\
v = e^{\lambda t} v_1, \quad \overline{v} = e^{\lambda T} v_2 \\
w = e^{\lambda t} w_1, \quad \overline{w} = e^{\lambda T} w_2 \\
p = e^{-\lambda t} p_1, \quad \overline{p} = e^{-\lambda T} p_2 \\
v = e^{-\lambda t} q_1, \quad \overline{q} = e^{-\lambda T} q_2 \\
r = e^{-\lambda t} r_1, \quad \overline{r} = e^{-\lambda T} r_2.
\end{align*}
\]

The variational inequality for \( u_0 \) becomes

\[
\int_{\Omega} [(u_0 - \overline{u}_0)_x (v_0 - u_0)_x + \left\{ e^{-\lambda t} (q_1 - p_1)(x, 0) + B_1 u_0 - B_2 (a - u_0) \right\} (v_0 - u_0)] \, dx \geq 0.
\]

Substituting \( v_0 = \overline{u}_0 \) in the \( u_0 \) variational inequality, and adding the resulting inequalities, we obtain

\[
\begin{align*}
&\int_{\Omega} (u_0 - \overline{u}_0)^2 + (B_1 + B_2)(u_0 - \overline{u}_0)^2 \\
&\leq \int_{\Omega} e^{-\lambda t} (u_0 - \overline{u}_0) ((q_1 - q_2) - (p_1 - p_2))(x, 0) \, dx.
\end{align*}
\]

Using the weak form of the state and adjoint systems and the above inequality, gives

\[
\begin{align*}
&\int_{\Omega} [(p_1 - p_2)^2 + (q_1 - q_2)^2 + (r_1 - r_2)^2] (x, 0) \, dx \\
&+ \int_{\Omega} [(u_1 - u_2)^2 + (v_1 - v_2)^2 + (w_1 - w_2)^2] (x, T) \, dx \\
&+ \lambda \int_{\Omega} [(u_1 - u_2)^2 + (v_1 - v_2)^2 + (w_1 - w_2)^2 + (p_1 - p_2)^2 + (q_1 - q_2)^2 + (r_1 - r_2)^2] \, dx \, dt \\
&+ \int_{\Omega} [(u_0 - \overline{u}_0)_x]^2 + (B_1 + B_2)(u_0 - \overline{u}_0)^2 \, dx + \int_{\Omega} d_1 \left( |(w_1 - w_2)_x|^2 + |(r_1 - r_2)_x|^2 \right) \, dx \, dt \\
&\leq (C_1 + C_2 e^{2\lambda T}) \left[ \int_{\Omega} [(u_1 - u_2)^2 + (v_1 - v_2)^2 + (w_1 - w_2)^2] \\
&+ (p_1 - p_2)^2 + (q_1 - q_2)^2 + (r_1 - r_2)^2 \right] \, dx \, dt \\
&+ \int_{\Omega} \frac{1}{2} [(p_1 - p_2)^2 + (q_1 - q_2)^2] (x, 0) \, dx + \frac{1}{2} \int_{\Omega} (u_0 - \overline{u}_0)^2 \, dx + \frac{1}{2} \int_{\Omega} (u_0 - \overline{u}_0)^2 \, dx,
\end{align*}
\]

where the last term comes from the initial conditions on \( u, v, \overline{u}, \overline{v} \). If we take \( \lambda \) large and then \( T \) small, we have

\[ \lambda - C_1 - C_2 e^{2\lambda T} > 0. \]

If we also assume \( B_1 + B_2 > \frac{5}{2} \), then we obtain the uniqueness.
5 Numerical Realization

We perform the numerical realization of the problem using the optimality system (3.2) that we recall thereafter:

\[
\begin{align*}
\frac{du}{dt} &= r_1 u(k_1 - u) - k_3 u w, \quad u(0) = u_o \\
\frac{dv}{dt} &= r_2 v(k_2 - v) - k_4 u w, \quad v(0) = a - u_o \\
\frac{\partial w}{\partial t} &= d_1 \frac{\partial^2 w}{\partial x^2} + (\alpha_1 k_3 u + \alpha_2 k_4 v - \mu) w, \quad w|_{x=0,x=1} = 0, \quad w(0) = w_o
\end{align*}
\]

(5.1)

\[
\begin{align*}
\frac{dp}{dt} &= (r_1 (k_1 - 2u) - k_3 w) p + \alpha_1 k_3 w r, \quad p(T) = A_1 \\
\frac{dq}{dt} &= (r_2 (k_2 - 2v) - k_4 w) q + \alpha_2 k_4 w r, \quad q(T) = A_2 \\
\frac{\partial r}{\partial t} &= d_1 \frac{\partial^2 r}{\partial x^2} + (\alpha_1 k_3 u + \alpha_2 k_4 v - \mu) r - k_3 u p - k_4 v q, \quad r|_{x=0,x=1} = 0, \quad r(T) = 0.
\end{align*}
\]

(5.2)

\[
\min_{0 \leq u_o \leq a} \frac{1}{2} \int_0^1 \left[ \frac{du_o}{dx} \right]^2 + (B_1 + B_2)u_o^2 - 2 (aB_2 + p(0) - q(0)) u_o \, dx.
\]

(5.3)

In the sequel, we set \( B = B_1 + B_2 \) and \( f = (B_3 + p(0) - q(0)) \).

These equations are coupled and we are going to solve this system via a relaxation method that can be roughly described as follows:

**Relaxation forward-backward method**

1. **Initialization step** Choose \( u_o \)

2. **Iteration** \( n : u_n \) is known.

   (a) Solve the forward system (5.1) : we get \( (u_n, v_n, w_n) \).

   (b) Solve the backward system (5.2) with \( (u_n, v_n, w_n) \) : we get \( (p_n, q_n, r_n) \).

   (c) Solve the Variational Inequality (5.3) with \( f_n = B_2 + p_n(0) - q_n(0) \) : we get \( u_{n+1} \).

3. Check a **stopping criterion** and set \( n = n + 1 \) if necessary.

The discretization of the system is done via finite difference methods with respect to the time variable and the space variable. The implicit Euler scheme is used to solve the forward system ODE’s and the space-discretized part of PDE’s and the Crank-Nicholson scheme is used for the backward (linear) system. This choice has been made using many numerical tests : though the Crank-Nicholson scheme is inconditionnally stable we could not avoid scattering for some examples that were particularly ill-conditionned. The state system (5.1) is a non-linear system, we use Newton’s method to solve it. The initial point
is chosen as the previous iterate so that the convergence is quite fast. Note that the ratio between the time discretization step and the space discretization step has to be small enough (CFL condition) to avoid numerical unstability.

To solve the Variational Inequality (5.3), we discretize the energy functional with the trapezoidal integration rule (for example) and use the classical projected gradient method to solve it. Indeed the functional is quadratic and constraints are bound constraints. The discretized problem turns out to be

$$\min \frac{1}{2}X' MX - F' X, \quad 0 \leq X_i \leq a, \ i = 1, \cdots, N+1$$

where $X = (u_o(x_i))_{i=1,N}$ is the discretized control function, $X'$ denotes the transpose of $X$, $F$ is the (space) discretized vector for $f = B_2 + p(0) - q(0)$ and $M = A + B Id$. Also $A$ is the discretized 1D-Laplacian matrix:

$$A = \frac{1}{(\Delta x)^2} \begin{bmatrix} 2 & -1 & 0 & \cdots & \cdots \\ -1 & 2 & -1 & 0 & \vdots \\ 0 & -1 & 2 & -1 & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots \\ \cdots & \cdots & \cdots & \cdots & -1 \\ \cdots & \cdots & \cdots & \cdots & 2 \end{bmatrix}$$

We have performed numerical tests with the following parameters:

<table>
<thead>
<tr>
<th>$r_1$</th>
<th>$r_2$</th>
<th>$d_1$</th>
<th>$k_1$</th>
<th>$k_2$</th>
<th>$\alpha_1$</th>
<th>$\alpha_2$</th>
<th>$k_3$</th>
<th>$k_4$</th>
<th>$\mu$</th>
<th>$\theta$</th>
<th>$A_1$</th>
<th>$A_2$</th>
