Abstract

We prove that the integrated density of states (IDS) of random Schrödinger operators with Anderson-type potentials on $L^2(\mathbb{R}^d)$, for $d \geq 1$, is locally Hölder continuous at all energies with the same Hölder exponent $0 < \alpha \leq 1$ as the conditional probability measure for the single-site random variable. As a special case, we prove that if the probability distribution is absolutely continuous with respect to Lebesgue measure with a bounded density, then the IDS is Lipschitz continuous at all energies. The single-site potential $u \in L^\infty(\mathbb{R}^d)$ must be nonnegative and compactly-supported. The unperturbed Hamiltonian must be periodic and satisfy a unique continuation principle. We also prove analogous continuity results for the IDS of random Anderson-type perturbations of the Landau Hamiltonian in two-dimensions. All of these results follow from a new Wegner estimate for local random Hamiltonians with rather general probability measures.

1 Introduction and Main Results

In this paper, we combine approaches of [4] and [6] to prove, as a special case, the Lipschitz continuity of the integrated density of states (IDS) for random Schrödinger operators $H_\omega = H_0 + V_\omega$, on $L^2(\mathbb{R}^d)$, for $d \geq 1$, provided the conditional probability distribution for the random variable at a single-site has a density in $L^\infty_0(\mathbb{R})$. In previous papers [6, 7], we proved global Hölder continuity, for any order strictly less than one, of the IDS under the same hypotheses on the single-site probability measure, and, in [18], there was an improvement up to a logarithmic factor (see below). It has long been expected that if the probability measure of a single-site random variable has a bounded density with compact support, then the IDS should be locally Lipschitz continuous at all energies. This is known to be true if the single-site potential satisfies a simple covering condition [4, 5]. This result is a special case of the continuity bound proved in this paper. We prove that if the conditional probability measure is Hölder continuous of order $0 < \alpha \leq 1$, then the IDS is Hölder continuous of order $\alpha$ at all energies. Hence, the IDS has at least the same continuity property as the conditional probability measure. These results follow from a Wegner estimate valid for a very general class of probability measures. We refer to [6] for an introduction to the problem and discussion of previous results.

The family of Schrödinger operators $H_\omega = H_0 + V_\omega$ on $L^2(\mathbb{R}^d)$, is constructed from a deterministic, periodic, background operator $H_0 = (-i\nabla - A_0)^2 + V_0$. We assume that this operator is self-adjoint with operator core $C_0^\infty(\mathbb{R}^d)$, and that $H_0 \geq -M_0 > -\infty$, for some finite constant $M_0$. We consider an Anderson-type potential $V_\omega$ constructed from the nonzero single-site potential $u \geq 0$ as

$$V_\omega(x) = \sum_{j \in \mathbb{Z}^d} \omega_j u(x - j). \quad (1.1)$$

We assume very little on the random variables $\{\omega_j \mid j \in \mathbb{Z}^d\}$ except that they form a bounded, real-valued process over $\mathbb{Z}^d$ with probability space $(\mathcal{P}, \Omega)$. We remark that the results of this paper also apply to the random operators describing acoustic and electromagnetic waves in randomly perturbed media, and we refer the reader to [11, 13, 14].

We need to define local versions of the Hamiltonians and potentials associated with bounded regions in $\mathbb{R}^d$. By $\Lambda_l(x)$, we mean the open cube of side length $l$ centered at $x \in \mathbb{R}^d$. For $\Lambda \subset \mathbb{R}^d$, we denote the lattice points in $\Lambda$
by $\tilde{\Lambda} = \Lambda \cap \mathbb{Z}^d$. For a cube $\Lambda$, we take $H_0^\Lambda$ and $H_\omega^\Lambda$ to be the restrictions of $H_0$ and $H_\omega$, respectively, to the cube $\Lambda$, with periodic boundary conditions on the boundary $\partial \Lambda$ of $\Lambda$. We denote by $E_0^\Lambda(\cdot)$ and $E_\Lambda(\cdot)$ the spectral families for $H_0^\Lambda$ and $H_\omega^\Lambda$, respectively. Furthermore, for $\Lambda \subset \mathbb{R}^d$, let $\chi_\Lambda$ be the characteristic function for $\Lambda$. The local potential $V_\Lambda$ is defined by

$$V_\Lambda(x) = V_\omega(x)\chi_\Lambda(x), \quad (1.2)$$

and we assume this can be written as

$$V_\Lambda(x) = \sum_{j \in \tilde{\Lambda}} \omega_j u(x - j). \quad (1.3)$$

For example, if the support of $u$ is contained in a single unit cube, formula (1.3) holds. We refer to the discussion in [6] when the support of $u$ is compact, but not necessarily contained inside one cube. In this case, $V_\Lambda$ can be written as in (1.3) plus a boundary term of order $|\partial \Lambda|$ and hence it does not contribute to the large $|\Lambda|$ limit. Hence, we may assume (1.3) without any loss of generality. We will also use the local potential obtained from (1.3) by setting all the random variables to one, that is,

$$V_\Lambda(x) = \sum_{j \in \tilde{\Lambda}} u(x - j). \quad (1.4)$$

We will always make the following four assumptions:

(H1). The background operator $H_0 = (-i \nabla - A_0)^2 + V_0$ is a lower semi-bounded, $\mathbb{Z}^d$-periodic Schrödinger operator with a real-valued, $\mathbb{Z}^d$-periodic, potential $V_0$, and a $\mathbb{Z}^d$-periodic vector potential $A_0$. We assume that $V_0$ and $A_0$ are sufficiently regular so that $H_0$ is essentially self-adjoint on $C^\infty_0(\mathbb{R}^d)$.

(H2). The periodic operator $H_0$ has the unique continuation property, that is, for any $E \in \mathbb{R}$ and for any function $\phi \in H^2_{loc}(\mathbb{R}^d)$, if $(H_0 - E)\phi = 0$, and if $\phi$ vanishes on an open set, then $\phi \equiv 0$.

(H3). The nonzero, nonnegative, compactly-supported, single-site potential $u \in L^\infty(\mathbb{R}^d)$, with $\|u\|_\infty \leq 1$, and it is strictly positive on a nonempty open set.
The nonconstant random coupling constants \( \{ \omega_j \mid j \in \mathbb{Z}^d \} \) take values in \([m_0, M_0]\) and form a real-valued, bounded process \(\mathbb{Z}^d\) with probability space \((\mathbb{P}, \Omega)\).

Note that the condition on \(\|u\|_\infty\) in (H3) can always be obtained by rescaling the random variables.

Our main technical result under hypotheses (H1)–(H4) is an optimal Wegner estimate expressed in Theorem 1.3. This upper bound (1.10) is optimal with respect to the volume dependence and the dependence on the distribution of the random variables. This implies the continuity results for the IDS expressed in Theorems 1.1–1.2. In order to describe the dependence on the probability measure \(\mathbb{P}\), we let \(\mu_j\) denote the conditional probability measure for the random variable \(\omega_j\) at site \(j \in \mathbb{Z}^d\), conditioned on all the random variables \((\omega_k)_{k \neq j}\), that is

\[
\mu_j([E, E + \epsilon]) = \mathbb{P}\{\omega_j \in [E, E + \epsilon] \mid (\omega_k)_{k \neq j}\}
\]  

The Wegner estimate and continuity results for the IDS are expressed in terms of the following quantity:

\[
s(\epsilon) \equiv \sup_{j \in \mathbb{Z}^d} IE \left\{ \sup_{E \in \mathbb{R}} \mu_j([E, E + \epsilon]) \right\}.
\]  

Clearly, if the \((\omega_j)_{j \in \mathbb{Z}^d}\) are independent, \(\mu_j\) is just the probability measure of the random variable \(\omega_j\). If, in addition, the random variables \(\omega_j\) are identically distributed, then all the \(\mu_j\) are the same, which we write as \(\mu_0\), and \((\mathbb{P}, \Omega)\) is the usual product probability space.

Our results on the Wegner estimate and the IDS are of greatest interest if the function \(s(\epsilon)\), defined in (1.6), satisfies \(s(\epsilon) \to 0\), when \(\epsilon \to 0^+\). In applications to continuity of the IDS or Anderson localization, the rate of vanishing of \(s(\epsilon)\), as \(\epsilon \to 0^+\), is essential. If, for example, in the case of independent and identically distributed (iid) random variables, the measure \(\mu_j\) is concentrated on a discrete set, our results do not provide this control.

We make two comments on hypotheses (H1)–(H4). First, concerning the unique continuation property, it is well known that \(H_0\) has the UCP if \(A_0\) and \(V_0\) are sufficiently regular; e.g. in dimension \(d \geq 3\), \(V_0 \in L_{loc}^{d/2}(\mathbb{R}^d)\), \(A_0 \in L_{loc}^d(\mathbb{R}^d)\) and \(\nabla A_0 \in L_{loc}^{d/2}(\mathbb{R}^d)\) are sufficient to ensure that \(H_0\) has the UCP (see e.g. [34] and references therein). It also follows that the Landau
Hamiltonian (1.7) has the UCP. Second, the boundedness of the random variables is not essential. The results can be generalized to a class of unbounded random variables.

We define the IDS $N(E)$ for $H_\omega$ using the counting function for $H^\Lambda_\omega$. Let $N_\Lambda(E)$ be the number of eigenvalues of $H^\Lambda_\omega$, with periodic boundary conditions, less than or equal to $E$. This function depends on the realization $\omega$. The integrated density of states (IDS) is defined by

$$N(E) = \lim_{|\Lambda| \to \infty} \frac{N_\Lambda(E)}{|\Lambda|},$$

when this limit exists. As assumptions (H1)-(H4) do not guarantee the existence of this limit, we will always assume the following.

(H5). The IDS $N(E)$ exists almost surely for the random family of operators considered here.

Because $N(E)$ is a monotonic function, we assume that $N(E)$ has been defined to be right continuous, and it has at most a countable number of discontinuities. For example, if the family $H_\omega$ is an ergodic family of random Schrödinger operators, it is known that this limit exists and is independent of the realization $\omega$ almost surely (cf. [3, 20, 26]). Furthermore, it is known that the IDS is independent of the boundary conditions taken on the finite volumes $\Lambda$, cf. [12, 20, 25]. Our main new result on the IDS is the following theorem.

Theorem 1.1 Assume that the family of random Schrödinger operators $H_\omega = H_0 + V_\omega$ on $L^2(\mathbb{R}^d)$, for $d \geq 1$, satisfies hypotheses (H1)-(H5). Then, for any $I \subset \mathbb{R}$ compact, there exists $C_I > 0$ such that for any $E \in I$ and for any $\epsilon \in (0, 1]$, one has

$$0 \leq N(E + \epsilon) - N(E) \leq C_I s(\epsilon),$$

where $s(\epsilon)$ is defined in (1.6).

As pointed out above, in order to apply this result to Anderson localization or to the continuity of the IDS, we need to impose conditions on the probability measure $P$ so that the function $\epsilon \mapsto s(\epsilon)$ vanishes as $\epsilon = 0^+$. A case of particular interest is when the random variables $(\omega_j)_{j \in \mathbb{Z}^d}$ satisfy
not only (H4) but are also iid with a common probability measure \( \mu_0 \) that is locally Hölder continuous of order \( 0 < \alpha \leq 1 \). That is, if for any interval \([a, b] \subset \text{supp } \mu_0\), we have \( \mu_0([a, b]) \leq C_0|b - a|^{\alpha} \), for some finite, positive constant \( C_0 > 0 \) (locally bounded). The function \( s(\epsilon) \) in (1.6) then satisfies \( s(\epsilon) \leq C_\mu \epsilon^{\alpha} \). Theorem 1.1 states that in this case the IDS \( N(E) \) for the random family \( H_\omega \) is locally Hölder continuous with uniform Hölder exponent \( \alpha \). That is, for any bounded, closed interval \( I \subset \mathbb{R} \), there is a finite positive constant \( 0 \leq C_I < \infty \), so that for any \( E, E' \in I \), the IDS satisfies
\[
|N(E') - N(E)| \leq C_I|E' - E|^{\alpha}.
\]

If \( \alpha = 1 \), then the IDS is locally Lipschitz continuous on \( \mathbb{R} \). This condition on the probability measure \( \mu_0 \) is stronger than just the absolute continuity of the probability measure as it implies that it admits a nonnegative, bounded, compactly-supported density \( h_0 \). Note that, in the iid case, the existence of the IDS is well known, hence, assumption (H5) can be dropped. We have the following simple, but important, corollary.

**Corollary 1.1** Suppose the random family satisfies (H1)-(H3) and the random variables \( (\omega_j)_{j \in \mathbb{Z}^d} \) are iid and the common probability measure \( \mu_0 \) is locally Lipschitz continuous and compactly supported. Then the IDS \( N(E) \) is locally uniformly Lipschitz continuous and the density of states \( \rho(E) \) exists as a locally bounded function.

We remark that Corollary 1.1 follows from the new analysis in section 2 and the spectral averaging result of [4] that is valid for a compactly-supported, Lipschitz continuous probability measure \( \mu_0 \). In particular, the new spectral averaging result presented in Theorem 3.1 is not needed for this case.

We next consider the IDS for random Anderson-type perturbations of Landau Hamiltonians. The unperturbed operator \( H_L(B) \) on \( L^2(\mathbb{R}^2) \) has the form
\[
H_L(B) = (-i\nabla - A)^2, \quad \text{where } A(x_1, x_2) = \frac{B}{2}(-x_2, x_1),
\]
where \( B > 0 \) is the magnetic field strength. The spectrum is pure point and consists of an increasing sequence of degenerate, isolated eigenvalues \( \{E_j(B) = (2j + 1)B \mid j = 0, 1, \ldots \} \) of infinite multiplicity. The unperturbed Hamiltonian \( H_L(B) \) satisfies the unique continuation principle as stated in
(H2). The IDS for this model is a piecewise constant, monotone increasing function (cf. the example in [25]). The perturbed family of operators is

$$H_\omega = H_L(B) + V_\omega,$$  \hspace{1cm} (1.8)

where $V_\omega$ is the Anderson-type random perturbation given in (1.1). It is known that $N(E)$ is locally Lipschitz continuous in the following sense. Given an $N > 0$, there is a $B_N > 0$ so that for $B > B_N$, the IDS $N(E)$ is Lipschitz continuous on $(0, 2(N + 1)B) \setminus \{ E_j(B) | j = 0, 1, \ldots, N \}$ [5, 31]. Under some additional conditions, Wang [32] also proved that $N(E)$ is smooth outside of a given Landau level for sufficiently large magnetic field strength. There has been some discussion as to the behavior of the IDS at the Landau energies $E_j(B)$. If the single-site potential $u$ in (1.1) has support including the unit cube $\Lambda_1(0)$ and satisfies $u|\Lambda_1(0) > \epsilon \chi_{\Lambda_1(0)} > 0$, for some $\epsilon > 0$, then the IDS is locally Lipschitz continuous at all energies [5]. The following theorem improves [6] and [7]. Note that the result holds for any nonzero flux.

**Theorem 1.2** Let $H_\omega$ be the perturbed Landau Hamiltonian (1.7)-(1.8) with magnetic field $B \neq 0$. Suppose that this family satisfies (H3)–(H5). Then, for any $I \subset \mathbb{R}$ compact, there exists $C_I > 0$ such that for any $E \in I$ and for any $\epsilon \in (0, 1]$, one has

$$0 \leq N(E + \epsilon) - N(E) \leq C_I s(\epsilon),$$

where $s(\epsilon)$ is defined in (1.6).

Of course the remarks following Theorem 1.1, in particular Corollary 1.1, hold for the randomly perturbed Landau Hamiltonian.

Both main results, Theorems 1.1 and 1.2, are proved by establishing a Wegner estimate for the local Hamiltonians $H_\Lambda$ and using the identity

$$|N(E + \epsilon) - N(E)| \leq \liminf_{|\Lambda| \to \infty} I E \left\{ \frac{1}{|\Lambda|} Tr E_\Lambda([E, E + \epsilon]) \right\},$$ \hspace{1cm} (1.9)

for $\epsilon$ small enough. We prove a new Wegner estimate in this paper that holds for general probability measures. The Wegner estimate is also essential in many proofs of Anderson localization using the method of multiscale analysis.
Theorem 1.3 Assume that the family of random Schrödinger operators $H_\omega = H_0 + V_\omega$ on $L^2(\mathbb{R}^d)$ satisfies hypotheses (H1)-(H4). Then, there exists a locally uniform constant $C_W > 0$ such that for any $E_0 \in \mathbb{R}$, and $\epsilon \in (0, 1]$, the local Hamiltonians $H_\Lambda$ satisfy the following Wegner estimate

$$\mathbb{P}\{\text{dist}(\sigma(H_\Lambda), E_0) < \epsilon\} \leq C_W s(2\epsilon)|\Lambda|,$$

(1.10)

where $s(\epsilon)$ is defined in (1.6). A similar estimate holds for randomly perturbed Landau Hamiltonians.

As an application of our results to a situation involving correlated random variables, we consider the family of nonsign definite single-site potentials introduced by Veselić [30]. Let $\Gamma \subset \mathbb{Z}^d$ be a finite set of vectors indexed by $k = 0, \ldots, |\Gamma| < \infty$ (we refer to $k \in \Gamma$). We consider a family of bounded, real-valued variables $\alpha_j$, for $j \in \Gamma$. We assume that $\sum_{j \neq 0} |\alpha_j| < |\alpha_0|$. This condition guarantees the invertibility of a certain Toeplitz matrix constructed from the $\alpha_j$. Let $w$ be a single-site potential as in (H3) and define a new single-site potential $u$ by

$$u(x) = \sum_{j \in \Gamma} \alpha_j w(x - j).$$

(1.11)

Since the coefficients are not required to have fixed sign, the potential $u$ is not sign definite. We now construct an Anderson-type random potential with iid random variables $\omega_j$ as in (1.1). Upon substituting the definition of $u$ in (1.11) into (1.1), we can write the potential as

$$V_\eta(x) = \sum_{j \in \mathbb{Z}^d} \eta_j u(x - j),$$

(1.12)

where the new family of random variables $\eta_j = \sum_{k \in \Gamma} \alpha_{j-k} \omega_k$ is no longer independent. They form a correlated process with finite-range determined by $\Gamma$. It is easy to compute the conditional probability measure $\mu_j$ for the random variables $\eta_j$ from the distribution for the variables $\omega_k$. In particular, if the single-site probability distribution $\mu_0$ for $\omega_0$ has a density, then so does the conditional probability measure $\mu_j$. Theorem 1.1 applies to this case and as a result the IDS is Lipschitz continuous at all energies. Veselić required that $u$ have a large support satisfying $u \geq C_0 \chi_{\Lambda_1(0)}$, but our results apply for $u$ as in (H3).
There are very few results on the Wegner estimate for general processes on $\mathbb{Z}^d$. In the iid case, Stollmann [28] considered a general compactly-supported probability measure $\mu_0$ and, using a completely different method, proved a Wegner estimate of the form (1.10) but with a volume factor of $|\Lambda|^2$, rather than $|\Lambda|$ as in Theorem 1.3. Stollmann’s result can be used to prove Anderson localization for Hölder continuous probability measures using the multiscale analysis but, because of the $|\Lambda|^2$-factor, cannot be used to study the IDS. More recently, Hundertmark, Killip, Nakamura, Stollmann, and Veselić [18] obtained a bound of the form $s(\epsilon)[\log(1/\epsilon)]^d|\Lambda|$, improving Stollmann’s bound to the correct volume factor, but under the strong assumption that $u \geq c_0 \chi_{\Lambda_1(0)}$, the characteristic function of the unit cube $\Lambda_1(0)$. In Theorem 1.3, this covering condition is no longer necessary. The result in [18] follows from a new exponentially decreasing bound, in the index $n$, on the $n^{th}$ singular value of the difference of two semigroups generated by Hamiltonians $H_1$ and $H_2$ for which the perturbation $H_1 - H_2$ has compact support. This estimate is used to improve the estimate on the spectral shift function obtained in [10]. Using these estimates, the authors improve the Hölder continuity of the IDS in the Hölder continuous situation studied in [6] obtaining $\epsilon[\log(1/\epsilon)]^d$, in place of $\epsilon^p$, for any $0 < p < 1$.

The contents of this paper are as follows. We prove Theorem 1.3, which implies Theorem 1.1, in section 2, assuming a key spectral averaging result. We prove this new spectral averaging result for general, compactly-supported probability measures in section 3. We prove the corresponding result, Theorem 1.2, for randomly perturbed Landau Hamiltonians, in section 4. In the first appendix, section 6, we prove some necessary trace estimates.

Applications of Theorem 1.3 to pointwise bounds on the expectation of the spectral shift function are presented in [8].

Acknowledgments. We thank M. Krishna in pointing out an error in an earlier version of this paper. The proof of Theorem 3.2 using maximally dissipative operators is due to J. H. Schenker whom we thank for numerous discussions.

2 Proof of Theorem 1.1

We now prove Theorem 1.1 via (1.9) by proving a Wegner estimate (1.10). We always assume that $u$ is nonzero so that $V_\omega$ is nonzero. Recall that by
the operators $H^\Lambda_0$ and $H^\Lambda_\omega$, we mean the operators $H_0$ and $H_\omega$ restricted to the cube $\Lambda$ with periodic boundary conditions. We will often write $H_\Lambda$ for $H^\Lambda_\omega$. Their spectral families are denoted by $E^\Lambda_0(\cdot)$ and $E_\Lambda(\cdot)$, respectively. In [6], we proved

**Theorem 2.1** Let $V : \mathbb{R}^d \to \mathbb{R}$ be a bounded, $\Gamma$-periodic, nonnegative function. Suppose that $V > 0$ on some open set. Consider a bounded interval $I \subset \mathbb{R}$. Then, there exists a finite constant $C(I, V) > 0$ such that, for any $\Lambda \subset \mathbb{R}^d$ cube with integral edges (i.e. vertices in $\mathbb{Z}^d$), one has,

$$E^\Lambda_0(I)V^\Lambda_0E^\Lambda_0(I) \geq C(I, V)E^\Lambda_0(I)$$

where $V_\Lambda$ is the restriction of $V$ to $\Lambda$.

This clearly yields that there exists a constant $C(\tilde{\Delta}, u) > 0$, independent of $\Lambda$, so that

$$E^\Lambda_0(\tilde{\Delta})V^\Lambda_0E^\Lambda_0(\tilde{\Delta}) \geq C(\tilde{\Delta}, u)E^\Lambda_0(\tilde{\Delta}).$$

(2.1)

For a fixed, but arbitrary, $E_0 \in \mathbb{R}$, let $E_0 \in \Delta \subset \tilde{\Delta}$ be two closed, bounded intervals centered on $E_0$, and let $d_\Delta \equiv \text{dist} (\Delta, \tilde{\Delta}^c)$. We will always assume that $d_\Delta > 0$.

Preparatory to the proof of Theorem 1.1, we note that hypothesis (H3) implies the following. There exists a finite constant $D_0 \equiv D_0(u, d) > 0$, depending only on the single-site potential $u$, and the dimension $d \geq 1$, so that for all $\Lambda \subset \mathbb{R}^d$,

$$0 \leq \tilde{V}^2_\Lambda \leq D_0(u, d)\tilde{V}_\Lambda,$$

(2.2)

where $\tilde{V}_\Lambda$ is defined in (1.4). We will use this in the proof.

**Proof of Theorem 1.1**

1. Recalling that $E_\Lambda(\Delta)$ is a trace class operator, we need to estimate

$$IE\{TrE_\Lambda(\Delta)\}.$$  

(2.3)

We begin with a decomposition relative to the spectral projectors $E^\Lambda_0(\cdot)$ for the operator $H^\Lambda_0$. We write

$$TrE_\Lambda(\Delta) = TrE_\Lambda(\Delta)E^\Lambda_0(\tilde{\Delta}) + TrE_\Lambda(\Delta)E^\Lambda_0(\tilde{\Delta}^c),$$

(2.4)

where the intervals $\Delta \subset \tilde{\Delta}$ satisfy $|\Delta| < 1$ and $d_\Delta > 0$. If $\tilde{\Delta}$, and consequently $\Delta$, lies in a spectral gap of $H^\Lambda_0$, then only the second term on the
right in (2.4) contributes and the result follows from (2.16). Hence, we only need to consider the case when \( \Delta \) does not lie in a spectral gap of \( H_0 \).

2. The term involving \( \tilde{\Delta}^c \) is estimated as follows. Since \( E_\Lambda(\Delta) \) is trace class, let \( \{ \phi^\Lambda_m \} \) be the set of normalized eigenfunctions in its range. We expand the trace in these eigenfunctions and obtain

\[
Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}^c) = \sum_m \langle \phi^\Lambda_m, E_0^\Lambda(\tilde{\Delta}^c) \phi^\Lambda_m \rangle. 
\] (2.5)

From the eigenfunction equation \( (H_\Lambda^\omega - E_m) \phi^\Lambda_m = 0 \), we easily obtain

\[-(H_0^\Lambda - E_m)^{-1} E_0^\Lambda(\tilde{\Delta}^c) V_\Lambda \phi^\Lambda_m = E_0^\Lambda(\tilde{\Delta}^c) \phi^\Lambda_m.\]

Substituting this into the right side of (2.5), and resumming to obtain a trace, we find

\[
Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}^c) = \sum_m \langle \phi^\Lambda_m, \left( V_\Lambda \frac{E_0^\Lambda(\tilde{\Delta}^c)}{(H_0^\Lambda - E_m)^2} V_\Lambda \right) \phi^\Lambda_m \rangle. 
\] (2.6)

We next want to replace the energy \( E_m \in \Delta \) in the resolvent in (2.6) by a fixed number, say \(-M\), assuming \( H_0^\Lambda > -M > -\infty \). To do this, we define an operator \( K \) by

\[
K \equiv \left( \frac{H_0^\Lambda + M}{H_0^\Lambda - E_m} \right)^2 E_0^\Lambda(\tilde{\Delta}^c), \] (2.7)

and note that \( K \) is bounded, independent of \( m \), by

\[
\|K\| \leq K_0 \equiv \left[ 1 + \frac{2(M + \Delta_+)}{d_\Delta} + \frac{(M + \Delta_+)^2}{d_\Delta^2} \right],
\]

where \( \Delta = [\Delta_-, \Delta_+] \). Now, for any \( \psi \in L^2(\mathbb{R}^d) \),

\[
\left\langle \psi, \frac{E_0^\Lambda(\tilde{\Delta}^c)}{(H_0^\Lambda - E_m)^2} \psi \right\rangle \leq \left\langle \frac{E_0^\Lambda(\tilde{\Delta}^c)}{(H_0^\Lambda + M)} \psi, K \frac{E_0^\Lambda(\tilde{\Delta}^c)}{(H_0^\Lambda + M)} \psi \right\rangle 
\]

\[
\leq K_0 \left\langle \psi, \frac{E_0^\Lambda(\tilde{\Delta}^c)}{(H_0^\Lambda + M)^2} \psi \right\rangle 
\]

\[
\leq K_0 \left\langle \psi, \frac{1}{(H_0^\Lambda + M)^2} \psi \right\rangle, \] (2.8)
since \( E_0^\Lambda (\tilde{\Lambda}) \leq 1 \). We use the bound \((2.8)\) on the right in \((2.6)\) and expand the potential. To facilitate this, let \( \chi \geq 0 \) be a function of compact support slightly larger than the support of \( u \), and so that \( \chi u = u \). We set \( \chi_j(x) = \chi(x-j) \), for \( j \in \mathbb{Z}^d \). Returning to \((2.6)\), we obtain the bound

\[
Tr E_\Lambda(\Delta) E_0^\Lambda (\tilde{\Lambda}) \leq K_0 \left( Tr E_\Lambda(\Delta) \left( V_\Lambda \frac{1}{(H_0^\Lambda + M)^2} V_\Lambda \right) \right)
\]

\[
\leq K_0 \sum_{i,j \in \tilde{\Lambda}} |\omega_i \omega_j| \left| Tr \left[ u_j E_\Lambda(\Delta) u_i \cdot \left( \chi_i \frac{1}{(H_0^\Lambda + M)^2} \chi_j \right) \right] \right|
\]

\[
\leq K_0 \sum_{i,j \in \tilde{\Lambda}} \left| Tr \left[ u_j E_\Lambda(\Delta) u_i \cdot \left( \chi_i \frac{1}{(H_0^\Lambda + M)^2} \chi_j \right) \right] \right| .
\]

\((2.9)\)

3. We divide the double sum in \((2.9)\) into two terms: For fixed \( i \in \tilde{\Lambda} \), one sum is over \( j \in \tilde{\Lambda} \) for which \( \chi_i \chi_j = 0 \), and in the second sum is over the remaining \( j \in \tilde{\Lambda} \) so that \( \chi_i \chi_j \neq 0 \). For the first sum, we note that the operator \( K_{ij} = \chi_i (H_0^\Lambda + M)^{-2} \chi_j \) in \((2.6)\) is trace class for \( d = 1, 2, 3 \).

Furthermore, we prove in Lemma 6.1 that the operator \( K_{ij} \) is trace class in all dimensions when \( \chi_i \chi_j = 0 \), and the trace norm \( \|K_{ij}\|_1 \) decays exponentially in \( ||i - j|| \) as

\[
\|K_{ij}\|_1 = \|\chi_i (H_0^\Lambda + M)^{-2} \chi_j\|_1 \leq C_0 e^{-c_0 ||i - j||},
\]

\((2.10)\)

for positive constants \( C_0, c_0 > 0 \) depending on \( M \). To control the second sum in \((2.9)\), we define, for each \( i \in \tilde{\Lambda} \), an index set \( \mathcal{J}_i = \{ j \in \tilde{\Lambda} \mid \chi_i \chi_j \neq 0 \} \). We note that \( |\mathcal{J}_i| \) depends only on \( u \), and is independent of \( i \) and \( \Lambda \). We define an operator \( \tilde{K}_\Lambda \) by

\[
\tilde{K}_\Lambda \equiv \sum_{i \in \tilde{\Lambda}, j \in \mathcal{J}_i} \chi_j K_{ij} \chi_i .
\]

\((2.11)\)

In Lemma 6.1, we prove that for any \( m > 0 \), and \( \sigma_j > 0 \), for \( j = 0, 1, \ldots, m \),

\[
\left| \sum_{i \in \tilde{\Lambda}, j \in \mathcal{J}_i} Tr u_j E_\Lambda(\Delta) u_i \cdot K_{ij} \right| \leq \left( \sum_{j=1}^{m} \frac{\sigma_j}{2^{j} \sigma_1 \cdots \sigma_{j-1}} \right) Tr E_\Lambda(\Delta) + \left( \frac{1}{2^m \sigma_1 \cdots \sigma_m} \right) Tr E_\Lambda(\Delta) \cdot \tilde{K}_\Lambda^{2^m} ,
\]

\((2.12)\)
and that if $m + 2 > \log d / \log 2$, the operator $\tilde{K}^{2m}$ is trace class and $\| \tilde{K}^{2m} \|_1 \leq C(\chi, m, d)|\Lambda|$. We next choose the $\sigma_j$ in Lemma 6.1 so that the term involving $\text{Tr} E_\Lambda(\Delta)$ in (2.12) can be moved to the left in (2.4). Since the coefficient in (2.9) is $K_0$, we choose $\sigma_1 = K_0^{-1}$, and successively $\sigma_j = K_0^{-2j-1}$. Then, the coefficient in (2.12) is $(1 - 2^{-m})K_0^{-1}$.

4. We now return to estimating the right side of (2.9). We have seen that in the disjoint support case, the operator $K_{ij} \in I_1$, and in the nondisjoint support case, we must work with $\tilde{K}^{2m}_\Lambda \in I_1$, for $m$ large enough. We first show how to control the expectation of the trace on the far right of (2.12). For simplicity, we write $n = 2m$ and recall the sets $J_{jk}$ defined in the proof of Lemma 6.1. First, we write this trace as

$$\text{Tr} E_\Lambda(\Delta) \cdot \tilde{K}^n_\Lambda = \sum_{i \in \tilde{\Lambda}, j \in J_{n-1}} \text{Tr} u_{jn} E_\Lambda(\Delta) u_i \cdot \tilde{K}(n)_{ij},$$

(2.13)

As in Lemma 6.1, the operator $K(n)_{ij}$ is trace class. The canonical representation of $K(n)_{ij}$ (where we write $j$ for $j_n$) is

$$K(n)_{ij} = \sum_l \mu_l^{(ij)} |\phi_l^{(ij)}\rangle \langle \psi_l^{(ij)}|$$

where $(\phi_l^{(ij)})_l$, $(\psi_l^{(ij)})_l$ are orthonormal families and $\sum_l |\mu_l^{(ij)}| < +\infty$.

Inserting this into the trace (2.13), we obtain

$$\text{Tr} E_\Lambda(\Delta) \cdot \tilde{K}^n_\Lambda \leq \sum_{i \in \tilde{\Lambda}, j \in J_{n-1}} \sum_l \mu_l^{(ij)} \langle \psi_l^{(ij)}, u_j E_\Lambda(\Delta) u_i \phi_l^{(ij)} \rangle \leq \sum_{i \in \tilde{\Lambda}, j \in J_{n-1}} \sum_l \mu_l^{(ij)} \left\{ \langle \psi_l^{(ij)}, u_j E_\Lambda(\Delta) u_j \psi_l^{(ij)} \rangle + \langle \phi_l^{(ij)}, u_i E_\Lambda(\Delta) u_i \phi_l^{(ij)} \rangle \right\}.$$  

(2.14)

We will prove in section 3 below that the expectation of the matrix elements in (2.14) satisfy the following bound

$$\mathbb{E} \{ \langle \psi_l^{(ij)}, u_j E_\Lambda(\Delta) u_j \psi_l^{(ij)} \rangle \} \leq 8s(|\Delta|),$$

(2.15)
where \( s(\epsilon) \) is defined in (1.6). It follows from (2.6)-(2.14) and the bound (2.15) that

\[
\mathbb{E}\{ \text{Tr} E_\Lambda(\Delta) \cdot \tilde{K}_n^n \} \leq \sum_{i \in \Lambda; j \in J_{n-1}} C(\chi)s(|\Delta|) \| \tilde{K}(n)_{ij} \|_1
\]

\[
\leq C(\chi, m)s(|\Delta|)|\Lambda|.
\]  

(2.16)

We use the same technique for the disjoint support terms for which the exponential decay in the trace norm (2.10) controls the double sum to give one factor of \(|\Lambda|\). Returning to (2.9), we obtain

\[
\mathbb{E}(\text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}^c)) \leq K_0 C(u, m)s(|\Delta|)|\Lambda|,
\]

plus a term involving \( \text{Tr} E_\Lambda(\Delta) \) with a coefficient less than one from (2.12) that is moved to the left in (2.4).

5. As for the first term on the right in (2.4), we use the fundamental assumption (2.1). As in [4], we will use the spectral projector \( E_0(\tilde{\Delta}) \) of \( H_0^A \) in order to control the trace. We have

\[
\text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}) \leq \frac{1}{C(\tilde{\Delta}, u)} \left\{ \text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}) \tilde{V}_A E_0^A(\tilde{\Delta}) \right\}
\]

\[
\leq \frac{1}{C(\tilde{\Delta}, u)} \left\{ \text{Tr} E_\Lambda(\Delta) \tilde{V}_A E_0^A(\tilde{\Delta}) - \text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}^c) E_0^A(\tilde{\Delta}) \right\}.
\]  

(2.17)

We estimate the second term on the right in (2.17). Using the Hölder inequality for trace norms, we have, for any \( \kappa_0 > 0 \),

\[
|\text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}^c) \tilde{V}_A E_0^A(\tilde{\Delta})| \leq \| E_\Lambda(\Delta) E_0^A(\tilde{\Delta}^c) \|_2 \| \tilde{V}_A E_0^A(\tilde{\Delta}) E_\Lambda(\Delta) \|_2
\]

\[
\leq \frac{1}{2\kappa_0} \text{Tr} E_0^A(\tilde{\Delta}^c) E_\Lambda(\Delta) + \frac{\kappa_0}{2} \text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}) \tilde{V}_A^2 E_0^A(\tilde{\Delta}) E_\Lambda(\Delta).
\]  

(2.18)

We next estimate the second term on the right in (2.18). Let \( D_0 \) be the constant in (2.2) so that \( \tilde{V}_A^2 \leq D_0 \tilde{V}_A \). Using this, we find that for any \( \kappa_1 > 0 \),

\[
\text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}) \tilde{V}_A^2 E_0^A(\tilde{\Delta}) E_\Lambda(\Delta)
\]

\[
\leq D_0 \| E_\Lambda(\Delta) E_0^A(\tilde{\Delta}) \tilde{V}_A \|_2 \| E_0^A(\tilde{\Delta}) E_\Lambda(\Delta) \|_2
\]

\[
\leq \frac{D_0 \kappa_1}{2} \text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}) \tilde{V}_A^2 E_0^A(\tilde{\Delta}) E_\Lambda(\Delta) + \frac{D_0}{2\kappa_1} \text{Tr} E_\Lambda(\Delta) E_0^A(\tilde{\Delta}).
\]
We choose \( \kappa_1 = 1/D_0 > 0 \) so that \( (1 - D_0\kappa_1/2) = 1/2 \). Consequently, we obtain
\[
Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}) \tilde{V}_\Lambda^2 E_0^\Lambda(\tilde{\Delta}) E_\Lambda(\Delta) \leq D_0^2 Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}). \tag{2.19}
\]
Inserting this into (2.18), we find
\[
|Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}^c) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})| \leq \frac{1}{2\kappa_0} Tr E_0^\Lambda(\tilde{\Delta}^c) E_\Lambda(\Delta) + \frac{\kappa_0 D_0^2}{2} Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}). \tag{2.20}
\]
As a consequence of (2.20), we obtain for the first term on the right in (2.4),
\[
\left(1 - \frac{\kappa_0 D_0^2}{2C(\Delta, u)}\right) Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}) \leq \frac{1}{C(\Delta, u)} |Tr E_\Lambda(\Delta) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})| + \frac{1}{2\kappa_0 C(\Delta, u)} Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}^c).
\]
We choose \( \kappa_0 = C(\tilde{\Delta}, u)/D_0^2 \) so that we have
\[
Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}) \leq \frac{2}{C(\tilde{\Delta}, u)} |Tr E_\Lambda(\Delta) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})| + \frac{D_0^2}{C(\tilde{\Delta}, u)^2} Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}^c). \tag{2.21}
\]
As for the first term on the right in (2.21), we use Hölder’s inequality and write
\[
|Tr E_\Lambda(\Delta) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})| \leq \|E_0^\Lambda(\tilde{\Delta}) E_\Lambda(\Delta)\|_2 \|E_\Lambda(\Delta) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})\|_2
\]
\[
\leq \frac{1}{2\sigma} \|E_0^\Lambda(\tilde{\Delta}) E_\Lambda(\Delta)\|_2^2 + \frac{\sigma}{2} \|E_\Lambda(\Delta) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})\|_2^2
\]
\[
\leq \frac{1}{2\sigma} Tr E_0^\Lambda(\tilde{\Delta}) E_\Lambda(\Delta) + \frac{\sigma}{2} Tr E_0^\Lambda(\tilde{\Delta}) \tilde{V}_\Lambda E_\Lambda(\Delta) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta}), \tag{2.22}
\]
for any constant \( \sigma > 0 \). In light of the coefficient in (2.21), we choose \( \sigma = 2/C(\tilde{\Delta}, u) \) and obtain from (2.21) and (2.22),
\[
Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}) \leq \frac{4}{C(\tilde{\Delta}, u)^2} Tr E_0^\Lambda(\tilde{\Delta}) \tilde{V}_\Lambda E_\Lambda(\Delta) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})
\]
\[
+ \frac{2D_0^2}{C(\tilde{\Delta}, u)^2} Tr E_\Lambda(\Delta) E_0^\Lambda(\tilde{\Delta}^c). \tag{2.23}
\]
The second term on the right in (2.23) is bounded above as in (2.14) and (2.16).

6. We estimate the first term on the right in the last line of (2.23). Let \( f_\Delta \in C^\infty_0(\mathbb{R}) \) be a smooth, compactly-supported, nonnegative function \( 0 \leq f \leq 1 \), with \( f_\Delta \chi_\Delta = \chi_\Delta \), where \( \chi_\Delta \) is the characteristic function on \( \Delta \). Note that we can take \( |\text{supp } f| \sim 1 \) so that the derivatives of \( f \) are order one. By positivity, we have the bound

\[
TrE_0^A(\tilde{\Delta})\tilde{V}_A E_\Lambda(\Delta)\tilde{V}_A E_0^A(\tilde{\Delta}) = TrE_\Lambda(\Delta)\tilde{V}_AE_0^A(\Delta)\tilde{V}_AE_\Lambda(\Delta) \leq TrE_\Lambda(\Delta)\tilde{V}_A f_\Delta(H_0^A)\tilde{V}_AE_\Lambda(\Delta).
\]

(2.24)

Recall that \( \chi_j \) is a compactly-supported function so that \( u_j \chi_j = u_j \). Upon expanding the potential \( \tilde{V}_A \), the term on the right in (2.24) is

\[
\sum_{j,k \in \tilde{\Lambda}} Tr u_k E_\Lambda(\Delta)u_j \cdot \chi_j f_\Delta(H_0^A) \chi_k.
\]

(2.25)

The operator \( \chi_j f_\Delta(H_0^A) \chi_k \) is a nonrandom, trace class operator. As with the operator \( K_{ij} \) in (2.9), it admits a canonical representation

\[
\chi_j f_\Delta(H_0^A) \chi_k = \sum_l \lambda_l^{(jk)} |\phi_l^{(jk)}\rangle \langle \psi_l^{(jk)}|,
\]

(2.26)

for orthonormal functions \( \phi_l^{(jk)} \) and \( \psi_l^{(jk)} \). This operator also satisfies a decay estimate of the type

\[
\|\chi_j f_\Delta(H_0^A) \chi_k\|_1 \leq C_N(f)(1 + \|k - j\|^2)^{-N},
\]

(2.27)

for any \( N \in \mathbb{N} \) and a finite positive constant depending on \( \|f^{(j)}\| \) independent of \( |\Delta| \). This can be proved using the Helffer-Sjöstrand formula, see, for example, [16]. Expanding the trace in (2.25) as in (2.14), we can bound (2.25) from above by

\[
TrE_0^A(\tilde{\Delta})\tilde{V}_A E_\Lambda(\Delta)\tilde{V}_A E_0^A(\tilde{\Delta}) = \sum_l \sum_{j,k \in \tilde{\Lambda}} \lambda_l^{(jk)} \langle \psi_l^{(jk)}, u_j E_\Lambda(\Delta)u_k \phi_l^{(jk)} \rangle
\]

\[
\leq \sum_l \sum_{j,k \in \tilde{\Lambda}} \lambda_l^{(jk)} \{ \langle \psi_l^{(jk)}, u_j E_\Lambda(\Delta)u_j \psi_l^{(jk)} \rangle + \langle \phi_l^{(jk)}, u_k E_\Lambda(\Delta)u_k \phi_l^{(jk)} \rangle \}.
\]

(2.28)
As in (2.16), the expectation of the matrix elements of the projector $E_\Lambda(\Delta)$ of the type occurring in (2.28) are bounded above as

$$IE\{\langle \xi, u_l E_\Lambda(\Delta) u_l \xi \rangle\} \leq 8s(|\Delta|), \quad (2.29)$$

where $\|\xi\| = 1$, and $s(\epsilon)$ is defined in (1.6). Given this bound, and the decay bound (2.27), we obtain

$$IE\{Tr E_0^\Lambda(\tilde{\Delta}) \tilde{V}_\Lambda E_0^\Lambda(\tilde{\Delta})\} \leq 2 \left( \sum_{j,k \in \tilde{\Lambda}} \|\chi_j f_{\Delta}(H_0^\Lambda) \chi_k\|_1 \right) C_0(u)s(|\Delta|)$$

$$\leq C_1(u)s(|\Delta|)|\Lambda|. \quad (2.30)$$

This estimate, together with estimate (2.16) and inequality (2.21), prove that

$$IE\{Tr E_\Lambda(\Delta)\} \leq C_2(u)s(|\Delta|)|\Lambda|. \quad (2.31)$$

This proves the Wegner estimate of Theorem 1.3. The results on the IDS in Theorem 1.1 now follows from this Wegner estimate, the additional Hölder continuity hypothesis, and the fact that

$$s(|\Delta|) \leq C_3|\Delta|^\alpha, \quad (2.32)$$

for some locally uniform constant $C_3 > 0$. □

3 Spectral Averaging for General Probability Measures

We now turn to the proof of (2.15) and (2.29) for general probability measures. As noted after Corollary 1.1 in section 1, a local Lipschitz condition on the random variables implies the existence of a bounded density $h_0 \in L^\infty_{loc}(\mathbb{R})$ with compact support. Hence, this case can be treated by the spectral averaging method of [4, 9, 23]. For the general case, we now present a new one-parameter averaging method.

We consider the one-parameter family of operators $H_\Lambda(\omega_j) = H_{j+}^\Lambda + \omega_j u_j$, where $H_{j+}^\Lambda$ is $H_\Lambda$ with $\omega_j = 0$. Let $E_0 \in \mathbb{R}$ be fixed and arbitrary. We consider an interval $\Delta_\epsilon = [E_0, E_0 + \epsilon]$, for some fixed $0 < \epsilon < \infty$. A simple
use of the spectral theorem for a self-adjoint operator \( H \) with spectral family \( E_H(\cdot) \) shows that

\[
\int_{\Delta_{\epsilon}} dE \left\langle \phi, 3(H - E - i\epsilon)^{-1}\phi \right\rangle = \left\langle \phi, \left[ \tan^{-1}\left( \frac{E_0 + \epsilon - H}{\epsilon} \right) - \tan^{-1}\left( \frac{E_0 - H}{\epsilon} \right) \right] \phi \right\rangle \geq (\tan^{-1}1)\left\langle \phi, E_H(\Delta_{\epsilon})\phi \right\rangle = (\pi/4)\left\langle \phi, E_H(\Delta_{\epsilon})\phi \right\rangle.
\] (3.1)

Applying this to the matrix element in (2.29), we obtain

\[
\left\langle \phi, u_j E_{\Lambda}(\Delta_{\epsilon})u_j\phi \right\rangle \leq \left( \frac{4}{\pi} \right) \int_{\Delta_{\epsilon}} dE \left\langle u_j\phi, \frac{1}{H_{\perp, j}^{\Lambda} + \omega_j u_j - E - i\epsilon u_j\phi} \right\rangle.
\] (3.2)

Our goal is to evaluate the expectation of the matrix element in (3.2) with respect to the random variable \( \omega_j \). To this end, we prove a new spectral averaging result that is a discretized version of previous spectral averaging results.

**Theorem 3.1** Let \( A \) and \( B \) be two self-adjoint operators on a separable Hilbert space \( \mathcal{H} \), and suppose that \( B \) is bounded and non negative. Then, for any \( \phi \in \mathcal{H} \), we have the bound

\[
\sum_{n \in \mathbb{Z}} \sup_{y \in [0,1]} \left\langle B\phi, \frac{1}{(A + (n + y)B)^2 + 1} B\phi \right\rangle \leq \pi \|B\| (1 + \|B\|) \|\phi\|^2.
\] (3.3)

The proof of Theorem 3.1 uses two technical tools: the following Lemma 3.1, the simple proof of which is left to the reader, and Theorem 3.2 that utilizes a basic result from the theory of maximally dissipative operators, that we briefly recall below.

For \( \kappa \in \mathbb{R} \), and \( b > 0 \), we define the function

\[
\ell(\kappa; b) = \sum_{n \in \mathbb{Z}} \sup_{y \in [0,1]} \frac{b}{(y + n + \kappa)^2 + b^2}.
\] (3.4)

**Lemma 3.1** For \( b > 0 \), the function \( \kappa \mapsto \ell(\kappa; b) \) is \( \mathbb{Z} \)-periodic and satisfies the bound

\[
\sup_{\kappa \in \mathbb{R}} \ell(\kappa; b) \leq \pi \left( 1 + \frac{1}{b} \right).
\] (3.5)
Next, we recall a main result in the theory of maximally dissipative operators (cf. [24, 29]). A closed operator $A$ is maximally dissipative if $\Re A \geq 0$ and $A$ has no proper dissipative extension.

**Proposition 3.1** Suppose $A$ is a maximally dissipative operator on a separable Hilbert space $\mathcal{H}$. Then, there exists a Hilbert space $\tilde{\mathcal{H}}$, containing $\mathcal{H}$ as a subspace, an orthogonal projection $P : \tilde{\mathcal{H}} \rightarrow \mathcal{H}$, and a self-adjoint dilation $L$ so that for $z \in \mathbb{C}$ with $\Re z < 0$,

$$(A - z)^{-1} = P(L - z)^{-1}P^*.$$  \hspace{1cm} (3.6)

Note that the signs of the imaginary parts in the denominator of the left side of (3.6) are the same. Consequently, the result is valid for an operator $A$ if $-A$ is maximally dissipative provided $\Re z > 0$. Also note that under the conditions in Proposition 3.1, we have $\Re (A - z)^{-1} \leq 0$.

**Lemma 3.1** and **Proposition 3.1** allows us to prove the following theorem.

**Theorem 3.2** Let $A$ be a maximally dissipative operator and let $B \geq 0$ be a bounded, nonnegative self-adjoint operator on a separable Hilbert space $\mathcal{H}$. Fix $\lambda > 0$. Then, for any $\phi \in \mathcal{H}$, we have the bound

$$-\sum_{n \in \mathbb{Z}} \sup_{y \in [0,1]} \Re \langle B^{1/2}\phi, \frac{1}{A + (n+y)B + i\lambda B}B^{1/2}\phi \rangle \leq \pi \left(1 + \frac{1}{\lambda} \right) \|\phi\|^2.$$  \hspace{1cm} (3.7)

**Proof:** Let $\delta > 0$ be a small parameter and set $B_\delta \equiv B + \delta > \delta$, since $B \geq 0$. As $B_\delta$ is bounded and invertible, we can write

$$\langle B_\delta^{1/2}\phi, \frac{1}{A + (n+y)B_\delta + i\lambda B_\delta}B_\delta^{1/2}\phi \rangle = \langle \phi, \frac{1}{B_\delta^{-1/2}AB_\delta^{-1/2} + (n+y) + i\lambda} \phi \rangle.$$  \hspace{1cm} (3.8)

Since $B \geq 0$ and bounded, and $A$ is maximally dissipative, so is $B_\delta^{-1/2}AB_\delta^{-1/2}$. Let $P$ and $L$ be the orthogonal projector and self-adjoint dilation associated with $B_\delta^{-1/2}AB_\delta^{-1/2}$ as in Proposition 3.1. Let $\mu_\psi$ be the spectral measure for $L$ and the vector $\psi$. We can write the matrix element in (3.8) as

$$\langle P^*\phi, \frac{1}{L + (n+y) + i\lambda}P^*\phi \rangle = \int_{\mathbb{R}} d\mu_L^{P^*\phi}(s) \frac{1}{s + (n+y) + i\lambda}.$$  \hspace{1cm} (3.9)
Inserting (3.9) into (3.8), taking the imaginary part, summing over \( n \in \mathbb{N} \), taking the supremum over \( y \in [0, 1] \), and using Fubini’s Theorem to intervert summation and integration, we obtain

\[
- \sum_{n \in \mathbb{Z}} \sup_{y \in [0,1]} \Im \langle B \delta^{1/2} \phi, \frac{1}{A + (n + y)B \delta + i\lambda B \delta} B \delta^{1/2} \phi \rangle \\
\leq \int_{\mathbb{R}} d\mu_{\mathcal{L}}(s) \left( \sup_{\kappa \in \mathbb{R}} \sum_{n \in \mathbb{Z}} \sup_{y \in [0,1]} \frac{\lambda}{(y + n + \kappa)^2 + \lambda} \right). \tag{3.10}
\]

By (3.5), the right side of (3.10) is bounded above by \( \pi (1 + \lambda^{-1}) \| \phi \|^2 \) and we obtain the bound (3.7) with \( B \delta \) in place of \( B \). Now, \( B \delta \rightarrow B \) in norm, and the resolvent \((A + (n + y)B \delta + i\lambda B \delta)^{-1}\) converges to \((A + (n + y)B + i\lambda B)^{-1}\), uniformly in \( y \). It follows that each term of the series in (3.7), with \( B \delta \) in place of \( B \), converges to the corresponding term with \( \delta = 0 \), and the result follows by Fubini’s Theorem. \( \square \).

**Proof of Theorem 3.1:** We derive Theorem 3.1 from Theorem 3.2. Pick \( 0 < \lambda < \| B \|^{-1} \). We write the matrix element on the left in (3.3) as

\[
\langle B\phi, \frac{1}{(A + (n + y)B)^2 + 1} B\phi \rangle = -\Im \langle B\phi, \frac{1}{A + (n + y)B + i} B\phi \rangle = -\Im \langle B\phi, \frac{1}{[A + (1 - \lambda B)i] + (n + y)B + i\lambda B} B\phi \rangle.
\]

The operator \( A + (1 - \lambda B)i \) is maximally dissipative as \( A \) is self-adjoint and \( 1 - \lambda B \geq 1 - \lambda \| B \| > 0 \) (see e.g. Lemma B.1 in [1]). We apply Theorem 3.2 with \( B \) replaced with \( B^{1/2} \phi \) and thus obtain

\[
\sum_{n \in \mathbb{Z}} \sup_{y \in [0,1]} \langle B\phi, \frac{1}{(A + (n + y)B)^2 + 1} B\phi \rangle \leq \pi (1 + \lambda^{-1}) \| B^{1/2} \phi \|^2 \\
\leq \pi \| B \| (1 + \lambda^{-1}) \| \phi \|^2.
\]

Letting \( \lambda \) tend to \( \| B \|^{-1} \), this immediately yields (3.3). This completes the proof of Theorem 3.1. \( \square \).

We can now prove the necessary estimate on the expectation of the integral in (3.2) for general probability measures.
Proposition 3.2 Let $\mu_j$ denote the probability measure of the random variable $\omega_j$ conditioned on all the random variables $(\omega_k)_{k \neq j}$ and let $s(\epsilon)$ be as defined in (1.6). Assume (H4) is satisfied. For any $\epsilon > 0$, let $\Delta_\epsilon \subset \mathbb{R}$ be an interval with $|\Delta_\epsilon| = \epsilon$. We have the following bound on the expectation of the energy integral appearing in (3.2):

$$\mathbb{E} \left\{ \int_{\Delta_\epsilon} dE \int_\mathbb{R} d\mu_j(\omega_j) \, \Im \langle \phi, u_j \left( \frac{1}{H_{j\perp}^\Lambda + \omega_j u_j - E - i\epsilon} \right) u_j \phi \rangle \right\} \leq 2\pi s(\epsilon) \|\phi\|^2.$$ (3.11)

Proof: The imaginary part of the matrix element in (3.11) is

$$\langle u_j \phi, \frac{\epsilon}{(H_{j\perp}^\Lambda - E + \omega_j u_j)^2 + \epsilon^2} u_j \phi \rangle = \frac{1}{\epsilon} \langle u_j \phi, \frac{1}{\epsilon^2(H_{j\perp}^\Lambda - E + \omega_j u_j)^2 + 1} u_j \phi \rangle.$$ (3.12)

To apply Theorem 3.1, we choose $B = u_j$ and define a self-adjoint operator $A \equiv \epsilon^{-1}(H_{j\perp}^\Lambda - E)$ so the matrix element in (3.12) may be written as

$$\langle B \phi, \frac{1}{(A + \epsilon^{-1}\omega_j B)^2 + 1} B \phi \rangle.$$ (3.13)

We divide the integration over $\omega_j$ into a sum over intervals $[n\epsilon, (n+1)\epsilon]$, and change variables letting $\omega_j/\epsilon = n + y$, so that $y \in [0, 1]$. We then obtain

$$\mathbb{E} \left\{ \int_\mathbb{R} d\mu_j(\omega_j) \langle B \phi, \frac{1}{(A + \epsilon^{-1}\omega_j B)^2 + 1} B \phi \rangle \right\}$$

$$= \mathbb{E} \left\{ \sum_n \int_{n\epsilon}^{(n+1)\epsilon} d\mu_j(\omega_j) \langle B \phi, \frac{1}{(A + \epsilon^{-1}(n+y)B)^2 + 1} B \phi \rangle \right\}$$

$$\leq \mathbb{E} \left\{ \left( \sup_{m \in \mathbb{Z}} \mu_j([m\epsilon, (m+1)\epsilon]) \right) \sum_n \sup_{y \in [0,1]} \langle B \phi, \frac{1}{(A + \epsilon^{-1}(n+y)B)^2 + 1} B \phi \rangle \right\}$$ (3.14)

We apply Theorem 3.1 to the last line in (3.14) and obtain

$$\mathbb{E} \left\{ \int_\mathbb{R} d\mu_j(\omega_j) \langle B \phi, \frac{1}{(A + \epsilon^{-1}\omega_j B)^2 + 1} B \phi \rangle \right\} \leq 2\pi \|\phi\|^2 \mathbb{E} \{|\sup_{m} \mu_j([m\epsilon, (m+1)\epsilon])|\}$$

$$\leq 2\pi \|\phi\|^2 s(\epsilon),$$ (3.15)
since \( \|B\| = \|u_j\| \leq 1 \). This provides a bound for the average over \( \omega_j \) of (3.12). Integrating in energy over \( \Delta_\epsilon \), and recalling the factor of \( \epsilon^{-1} \) in (3.12), we obtain the estimate (3.11). \( \square \)

We combine (3.1) with (3.11) to obtain

\[
IE\{\langle \phi, u_j E_\Lambda(\Delta) u_j \phi \rangle \} \leq 8s(\epsilon)\|\phi\|^2,
\]

(3.16)

which is (2.15) and (2.29).

## 4 The Integrated Density of States for Random Landau Hamiltonians

The method of proof in section 2 can be adapted to treat randomly perturbed Landau Hamiltonians. The unperturbed Landau Hamiltonian \( H_L(B) \) on \( L^2(\mathbb{R}^2) \) is described in (1.7), and the perturbed operator \( H_\omega \) in (1.8). The random potential \( V_\omega \) is Anderson-type as in (1.1). A quantitative version of the unique continuation principle for infinite-volume Landau Hamiltonians, analogous to (2.1), was proved in [7]. We note that this result holds independent of the flux.

**Theorem 4.1** Let \( H_L(B) \) be the Landau Hamiltonian in (1.7) and let \( \Pi_n \) be the projector onto the infinite-dimensional eigenspace for \( H_L(B) \) corresponding to the eigenvalue \( E_n(B) \). Let \( u \geq 0 \), the single-site potential, be a nonnegative, compactly-supported function with \( u \in L^\infty(\mathbb{R}^2) \), and satisfying \( u > u_0 > 0 \) on some nonempty open set, for some constant \( u_0 > 0 \). We define the potential \( \tilde{V} \) by

\[
\tilde{V}(x) \equiv \sum_{j \in \mathbb{Z}^2} u(x - j).
\]

Then, there exists a finite constant \( 0 < C_n(B, u) < \infty \), so that

\[
\Pi_n \tilde{V} \Pi_n \geq C_n(B, u) \Pi_n.
\]

(4.1)

This infinite-volume result was used in [7] to prove the local Hölder continuity of the IDS, and could be used here to improve the result to local Hölder continuity with exponent \( 0 < \alpha \leq 1 \). However, it is easier to pursue a purely local result and also obtain a Wegner estimate. Motivated by transport questions for random Landau Hamiltonians (1.8), Germinet, Klein, and
Schenker [17] used the result (4.1) to prove a purely local version of the quantitative unique continuation principle. This allowed them to prove a Wegner estimate for Landau Hamiltonians at any energy, including the Landau levels. With this result, we show how to use the method of proof in section 2 to obtain an improved Wegner estimate and, consequently, an improved continuity estimate on the IDS.

As in [17], given a magnetic field strength $B > 0$, we define a number $K_B \equiv \min\{k \in \mathbb{N} \mid k \geq \sqrt{B/4\pi}\}$, and a length scale $L_B \equiv K_B\sqrt{B/4\pi}$. Corresponding to $L_B$ we define a set of length scales $N_B = L_B\mathbb{N}$. For squares of side length $L_B N$, the flux is an even integer. The local, unperturbed Landau Hamiltonians $H^0_{\Lambda_L}(B)$ are defined on squares $\Lambda_L(0)$, with $L \in N_B$, with periodic boundary conditions consistent with the magnetic translations. The spectrum of these local operators is discrete and consists of finite multiplicity eigenvalues at the Landau levels $E_n(B)$. We denote by $\Pi_n,L$ the finite rank projection onto the eigenspace corresponding to the $n$th Landau level $E_n$. The local random Hamiltonians associated with squares $\Lambda_L(0)$ are defined by $H^\Lambda(B) = H^0_{\Lambda_L}(B) + V_\Lambda$, where

$$V_\Lambda(x) = \sum_{j \in \Lambda_{L - \delta_u}(0)} \omega_j u(x - j),$$

and $\text{supp } u \subset \Lambda_{\delta_u}(0)$. We obtain local Hamiltonians for squares $\Lambda_L(x)$ by conjugation with the magnetic translation group operators considered as maps from $L^2(\Lambda_L(0)) \to L^2(\Lambda_L(x))$. We always consider $B > 0$ fixed.

**Theorem 4.2** [17] There exists a finite, positive constant $C(n,u) > 0$, independent of $L \in N_B$ large enough, so that

$$\Pi_{n,L} \tilde{V}_\Lambda \Pi_{n,L} \geq C(n,u)\Pi_{n,L}. \quad (4.2)$$

We now sketch the proof of the following Wegner estimate from which the main Theorem 1.2 follows. The local random Hamiltonians $H^\Lambda(B)$ are defined above with $L \in N_B$ and periodic boundary conditions determined by the magnetic translations.

**Theorem 4.3** We assume hypotheses (H3)-(H4), and let $I \subset \mathbb{R}$ be a bounded interval. There is a finite constant $C_W \equiv C_{B,u,I} > 0$, and a length scale $L_{B,I}$, so that for any subinterval $\Delta \subset I$ small enough, and for any $L \in N_B$ with $L > L_{B,I}$, we have

$$\mathbb{E}\{\text{Tr}(E_{\Lambda_L}(\Delta))\} \leq C_W s(|\Delta|)L^2,$$
where $s(\epsilon)$ is defined in (1.6).

**Sketch of the Proof of Theorem 4.3.**

1. We write $\Lambda$ for $\Lambda_L$, where $L$ is a permissible length as described above. Without loss of generality, we assume that $I$, and the subinterval $\Delta \subset I$ contains only the Landau level $E_n(B)$ and no other Landau level. Let $E_0 \in \Delta$ be the center of the interval. We write the decomposition in (2.4) using the unperturbed projector $\Pi_{n,L}$,

$$Tr E_\Lambda(\Delta) = Tr E_\Lambda(\Delta)\Pi_{n,L} + Tr E_\Lambda(\Delta)\Pi_{n,L}^\perp. \quad (4.3)$$

For the complementary term on the right in (4.3), we follow the argument in (2.5)–(2.14). We can take, for example, $M = 1$ in (2.7). We easily derive the analog of (2.9),

$$Tr E_\Lambda(\Delta)\Pi_{n,L}^\perp \leq K_n \sum_{i,j \in \tilde{\Lambda}} Tr \left[ u_j E_\Lambda(\Delta) u_i \cdot \left( \chi_i \left( \frac{1}{H^0_{\Lambda_L}(B) + 1} \right) \chi_j \right) \right], \quad (4.4)$$

(4.5)

where the constant $K_n$ depends on the Landau level $n$ and is expressible in the form of (2.11) with $d_{\Delta}$ there replaced by

$$d_n = \min( \text{dist } (I, E_{n-1}(B)), \text{dist } (I, E_{n+1}(B))).$$

The operator $K_{ij} \equiv \chi_i \left( \frac{1}{H^0_{\Lambda_L}(B) + 1} \right)^{-2} \chi_j$ is trace class (cf. [5]) and satisfies an exponential decay estimate analogous to (2.10). Completing the argument to (2.16), we obtain

$$IE \{ Tr E_\Lambda(\Delta)\Pi_{n,L}^\perp \} \leq K_n C_0 s(|\Delta|) L^2.$$

2. We now estimate the first term on the right in (2.3) using the unique continuation principle (4.2),

$$Tr E_\Lambda(\Delta)\Pi_{n,L} \leq \frac{1}{C(n, u)} \left\{ Tr E_\Lambda(\Delta)\tilde{V}_\Lambda \Pi_{n,L} - Tr E_\Lambda(\Delta)\Pi_{n,L}^\perp \tilde{V}_\Lambda \Pi_{n,L} \right\}. \quad (4.6)$$

23
We estimate the second term on the right in (4.6) as in (2.18)–(2.19), and obtain a bound similar to (2.20),

$$|\text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L}^{\perp} \tilde{V}_{\Lambda} \Pi_{n,L}| \leq \frac{1}{2\kappa_0} \text{Tr} \Pi_{n,L} \Pi_{n,L} E_{\Lambda}(\Delta) + \frac{\kappa_0 D_0^2}{2} \text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L},$$

(4.7)

where we used the constant $D_0$ from (2.2). We now substitute (4.7) into the right of (4.6) and obtain the analog of (2.21),

$$\left(1 - \frac{\kappa_0 D_0^2}{2C(n, u)}\right) \text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L} \leq \frac{1}{2\kappa_0 C(n, u)} \text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L}^{\perp}$$

$$+ \frac{1}{C(n, u)} |\text{Tr} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} \Pi_{n,L}|.$$

(4.8)

We choose $\kappa_0 = C(n, u)/D_0^2$, and obtain from (4.8) an estimate for the left side of (4.6),

$$\text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L} \leq \frac{2}{C(n, u)} |\text{Tr} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} \Pi_{n,L}| + \frac{D_0^2}{C(n, u)^2} \text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L}^{\perp}.$$

We follow the same method to estimate the first term on the right in (4.8) and obtain finally the analog of (2.23),

$$\text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L} \leq \frac{2D_0^2}{C(n, u)^2} \text{Tr} E_{\Lambda}(\Delta) \Pi_{n,L}^{\perp} + \frac{4}{C(n, u)^2} \text{Tr} \Pi_{n,L} \tilde{V}_{\Lambda} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} \Pi_{n,L}.$$

3. We now estimate $\text{Tr} \Pi_{n,L} \tilde{V}_{\Lambda} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} \Pi_{n,L}$ as in the proof of Theorem 1.1. As in (2.24), we first write

$$\text{Tr} \Pi_{n,L} \tilde{V}_{\Lambda} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} \Pi_{n,L} = \text{Tr} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} \Pi_{n,L} \tilde{V}_{\Lambda} E_{\Lambda}(\Delta)$$

$$\leq \text{Tr} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} f_n(H^0_{\Lambda L}(B)) \tilde{V}_{\Lambda} \Pi_{n,L},$$

where $f_n \in C^\infty_0(\mathbb{R})$ is equal to one near $E_n(B)$. We expand the potential and obtain

$$\text{Tr} \Pi_{n,L} \tilde{V}_{\Lambda} E_{\Lambda}(\Delta) \tilde{V}_{\Lambda} \Pi_{n,L} \leq \sum_{i,j \in \Lambda} \text{Tr} \ u_j E_{\Lambda}(\Delta) u_i \cdot \chi_i f_n(H^0_{\Lambda L}(B)) \chi_j.$$

Following a similar analysis as from (2.26) to (2.30), we obtain

$$IE \{\text{Tr} E_{\Lambda}(\Delta)\} \leq C_3(n, u)s(|\Delta|)L^2,$$

according to hypothesis (H4). □
6 Appendix: Trace-class Estimates

For the purposes of this appendix, we let $u \in L_0^\infty(\mathbb{R}^d)$ denote a compactly-supported function and write $u_j(x) = u(x - j)$, for $j \in \mathbb{Z}^d$. We note that the operator $K_{ij} = u_i(H_0^\Lambda + M)^{-2}u_j$ (similar to the operator in (2.10)) is trace class for $d = 1, 2, 3$. For higher dimensions, $d > 3$, we proceed as follows. The operator $u_i(H_0^\Lambda + M)^{-1} \in \mathcal{I}_q$, where $\mathcal{I}_q$ is the $q$th-von Neumann Schatten class, provided $q > d/2$ (cf. [27]). We state the essential properties in the following lemma.

Lemma 6.1 Let $u \in L^\infty(\mathbb{R}^d)$ be a compactly-supported function centered about the origin and set $u_j(x) = u(x - j)$, for $j \in \hat{\Lambda}$, so that $u_j$ is a compactly-supported function centered about $j \in \hat{\Lambda}$. We assume that $H_0^\Lambda + M$ is boundedly invertible for some $M > 0$, and for all $\Lambda$.

1. The bounded operator $K_{ij} = u_i(H_0^\Lambda + M)^{-2}u_j$ is trace class if $u_iu_j = 0$. In this case, there are constants $c_0, C_0 > 0$, independent of $\Lambda$, and $i, j$, so that
   \[ \|K_{ij}\|_1 = \|u_i(H_0^\Lambda + M)^{-2}u_j\|_1 \leq C_0 e^{-c_0\|i-j\|}. \]

2. The operator $(H_0^\Lambda + M)^{-1}u_j \in \mathcal{I}_q$, for any $q > d/2$. Let $J_i = \{j \in \hat{\Lambda} | u_iu_j \neq 0\}$, and define
   \[ \tilde{K}_\Lambda = \sum_{i \in \Lambda; j \in J_i} u_i K_{ij} u_j. \]

Then, for any $m > 0$, any $\sigma_j > 0$, with $\sigma_0 = 1$, we can express the partial sum of the trace in (2.9) in the following form:

\[ \left| \sum_{i \in \Lambda; j \in J_i} \text{Tr} \ E_\Lambda(\Delta) \cdot u_i K_{ij} u_j \right| \leq \left( \sum_{j=1}^m \frac{\sigma_j}{2^j \sigma_1 \cdots \sigma_{j-1}} \right) \text{Tr} E_\Lambda(\Delta) + \left( \frac{1}{2^m \sigma_1 \cdots \sigma_m} \right) \text{Tr} \ E_\Lambda(\Delta) \cdot \tilde{K}_\Lambda^{2m}. \]

If $m + 2 > \log d / \log 2$, the operator $\tilde{K}_\Lambda^{2m}$ is trace class and $\|\tilde{K}_\Lambda^{2m}\|_1 \leq C(u, m, d)|\Lambda|$. 

25
Proof.
1. **Disjoint Support, Off-Diagonal Terms.** We first consider separately the terms $K_{ij}$ for which we have disjoint supports: $u_i u_j = 0$. Let $R_0 \equiv (H_0^\Lambda + M)^{-1}$ for notational convenience. Let $\chi$, $\tilde{\chi}$, and $\tilde{\chi}$ be a smooth, compactly-supported function with values in $[0, 1]$, and such that $\chi u = u$. We choose $\tilde{\chi}$ so that $\tilde{\chi} \chi = \chi$. We denote by $W(\chi)$ the first-order localized operator $W(\chi) \equiv [\chi, H_0]$, and we set $\chi_j(x) = \chi(x - j)$, similarly for $\tilde{\chi}$. If $u_i u_j = 0$, then we can choose $\chi$ and $\tilde{\chi}$ so that $\chi_j u_i = 0 = \tilde{\chi}_j u_i$. Finally, we take $\tilde{\chi}_j$ so that $\tilde{\chi}_j W(\tilde{\chi}_j) = W(\tilde{\chi}_j)$. In the disjoint support case, we have

$$u_i R_0^2 u_j = \underbrace{u_i R_0^2 \chi_j u_j}_1 = \underbrace{u_i R_0^2 W(\chi_j) R_0 u_j + u_i R_0 \chi_j R_0 u_j}_2 = \underbrace{u_i R_0^2 W(\chi_j) R_0 u_j + u_i R_0 W(\chi_j) R_0^2 u_j}_3 = \underbrace{u_i R_0^2 W(\tilde{\chi}_j) R_0 W(\tilde{\chi}_j) R_0 u_j + u_i R_0 W(\tilde{\chi}_j) R_0^2 W(\chi_j) R_0 u_j}_4 + u_i R_0 W(\tilde{\chi}_j) R_0 W(\chi_j) R_0^2 u_j. \quad (6.1)$$

The operator $(H_0^\Lambda + M)^{-1} u_j \in \mathcal{I}_q$, for any $q > d/2$. If we suppose that $q = 3$, for example, then the Hölder inequality applied to the first term in (6.1) implies that

$$\|u_i R_0^2 W(\tilde{\chi}_j) R_0 W(\chi_j) R_0 u_j\|_1 \leq \|u_i R_0\|_3 \|R_0 W(\tilde{\chi}_j) R_0 W(\chi_j)\|_3 \|R_0 u_j\|_3 \leq \|u_i R_0\|_3 \|R_0 \tilde{\chi}_j\|_3 \|R_0 u_j\|_3 \|W(\tilde{\chi}_j) R_0 W(\chi_j)\| < \infty, \quad (6.2)$$

since the operator norm on the last line of (6.2) is bounded. It is clear that this extends the result to $d = 4, 5$. Iterating this scheme with finitely-many cut-off functions, and recalling that the operator $W(\chi) (H_0^\Lambda + M)^{-1} \in \mathcal{I}_q$, for any $q > d$, we see that $u_i R_0^2 u_j$ is trace class in any dimension provided $u_i u_j = 0$. The exponential decay in the trace norm can be proved using the Combes-Thomas method, cf. [2].

2. **Nondisjoint Support Terms.** Let $\|A\|_2$ denote the Hilbert-Schmidt norm of an operator $A$. For $i \in \tilde{\Lambda}$, we let $\mathcal{J}_i \equiv \{ j \in \tilde{\Lambda} \mid u_i u_j \neq 0 \}$, and define

$$\bar{K}_\Lambda \equiv \sum_{i \in \tilde{\Lambda}, j \in \mathcal{J}_i} u_i K_{ij} u_j.$$

Note that $|\mathcal{J}_i|$ is finite, independent of $i$, depends only on supp $u$, and so is independent of $|\Lambda|$. Then we can express the sum of the nondisjoint support
terms occurring in (2.9) in the following form:

$$\left| \sum_{i \in \bar{\Lambda}, j \in J} \text{Tr} \, u_j E_\Lambda(\Delta) u_i \cdot K_{ij} \right| = |\text{Tr} E_\Lambda(\Delta) \tilde{K}_\Lambda|$$

$$\leq \|E_\Lambda(\Delta)\|_2 \|E_\Lambda(\Delta) \tilde{K}_\Lambda\|_2$$

$$\leq \frac{\sigma_1}{2} \text{Tr} E_\Lambda(\Delta) + \frac{1}{2\sigma_1} \text{Tr} E_\Lambda(\Delta) \tilde{K}_\Lambda^2,$$

for any $\sigma_1 > 0$. We iterate this expression $m$ times and obtain

$$|\text{Tr} E_\Lambda(\Delta) \tilde{K}_\Lambda| \leq \left( \sum_{j=1}^{m} \frac{\sigma_j}{2^j \sigma_1 \cdots \sigma_{j-1}} \right) \text{Tr} E_\Lambda(\Delta)$$

$$+ \left( \frac{1}{2^m \sigma_1 \cdots \sigma_m} \right) \text{Tr} E_\Lambda(\Delta) \cdot \tilde{K}_\Lambda^{2m},$$

where $\sigma_0 \equiv 1$. To describe the operator $\tilde{K}_\Lambda^n$, we define an index set $J_{jk} \equiv \{m \in \bar{\Lambda} \mid u_m u_{jk} \neq 0\}$. We can then write

$$\tilde{K}_\Lambda^n = \sum_{i \in \bar{\Lambda}, j_k \in J_{jk}, k=1, \ldots, n; j_0 = i} u_i^2 R_0^2 u_j^2 u_{j_1}^2 R_0^2 u_{j_2}^2 R_0^2 u_{j_3}^2 R_0^2 \cdots u_{j_{n-1}}^2 R_0^2 u_{j_n}^2.$$ 

Since $u_i R_0^2 u_j \in \mathcal{I}_q$, for any $q > d/4$, Hölder’s inequality implies that $\tilde{K}_\Lambda^n \in \mathcal{I}_1$ if $n > d/4$. It is clear then for $m + 2 > \log d / \log 2$, the operator $\tilde{K}_\Lambda^{2m} \in \mathcal{I}_1$. Finally, we easily estimate the trace norm:

$$\|\tilde{K}_\Lambda^{2m}\|_1 \leq C(u, m, d)|\Lambda|,$$

for a constant $0 < C(u, m, d) < \infty$ independent of $|\Lambda|$. □
