Abstract The problem of semi-global minimal time robust stabilization of the Brockett integrator (also called Heisenberg system) is addressed and solved by means of a hybrid state feedback law. It is shown that the solutions of the closed-loop system converge to the origin, in quasi-minimal time (for a given bound on the controller), with a robustness property with respect to small measurement noises, external disturbances and actuator noises.

Key words Brockett integrator – optimal control – hybrid feedback – robust stabilization – measurement errors – actuator noise – external disturbances

1 Introduction

Consider the so-called *Brockett system* in \mathbb{R}^3

$$\dot{x} = u_1 f_1(x) + u_2 f_2(x), \quad (1)$$

where, denoting $x = (x_1, x_2, x_3)$,

$$f_1 = \frac{\partial}{\partial x_1} + x_2 \frac{\partial}{\partial x_3}, \quad f_2 = \frac{\partial}{\partial x_2} - x_1 \frac{\partial}{\partial x_3}, \quad (2)$$

and the control function $u = (u_1, u_2)$ satisfies the constraint

$$u_1^2 + u_2^2 \leq 1. \quad (3)$$

The system (1), together with the constraint (3), is said to be *globally asymptotically stabilizable* at the origin, if, for each point x of \mathbb{R}^3 , there exists a control law $x \mapsto u(x)$, satisfying the constraint (3), such that the solution of (1), associated to this control law, and starting from x , tends to 0 as t tends to $+\infty$.

Note that, due to Brockett's condition (see [9, Theorem 1, (iii)]), there does not exist any continuous stabilizing feedback law $x \mapsto u(x)$ for (1). Several control laws have been however derived for control systems of this type (see *e.g.* [16,13,3] and references therein).

The robust asymptotic stabilization problem is under current and active research. There exists a large variety of control laws that solve the robust asymptotic stabilization problem, such as discontinuous sampling feedbacks [10,25], time varying control laws [12,11,17,18], patchy feedbacks (as in [1]),

SRS feedbacks [24], ..., yielding different robustness properties depending on the errors under consideration in these papers.

The class of feedbacks considered here consists of feedback laws mixing discrete and continuous components. It gives rise to closed-loop systems with a hybrid term, studied *e.g.* in [28,6]. The use of such a class of feedbacks for the stabilization of nonlinear systems (*a priori* without discrete state) first appeared in [20]. It allows to design a switching strategy between different smooth control laws defined on a partition of the state space. This idea of defining the control smoothly part by part, and switching between the different components, is usual in nonlinear control theory (see *e.g.* [27,2]). It has also been applied in [23] to chained systems with two commands. However, in this paper, we provide, as in [23], a hybrid feedback law for the system (1) with the constraint (3), that is not only robustly stabilizing, but also enjoys a minimal time property. It consists, on the one hand, of a minimal time controller, that is smooth on a part of the state space, and on the other, of a second controller, defined on the complement of this part, and we define the switching strategy between both control laws. Our strategy enjoys a minimal time property, and robustness with respect to (small) measurement noises, actuator errors and external disturbances.

To this aim, we first solve the minimal time control problem, for the system (1) with the constraint (3), and then, we define a hybrid feedback law, using a suitable switching strategy (namely, a hysteresis) between this

minimal time controller and another controller defined on a neighborhood of the singular set of the optimal control law.

The paper is organized as follows. First, we recall a notion of solution adapted to hybrid feedback laws, and make precise the notion of stabilization via a minimal time hybrid feedback law. We then state the main result, namely, that there exists a minimal time hybrid feedback law stabilizing semi-globally and robustly the origin for the system (1) with the constraint (3) (see Section 3). The rest of the paper is devoted to the proof of this result. We recall how to solve explicitly the minimal time problem for the system (1) with the constraint (3), and define our “local” minimal time control law in Section 4.1, and the “global” one in Section 4.2. The hybrid feedback law is defined in Section 5, and the main result is proved in Section 6.

2 Class of controllers and notion of solution

Let n and m be positive integers, and $f : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ be a continuous function, which is locally Lipschitzian in $x \in \mathbb{R}^n$, uniformly for $u \in \mathbb{R}^m$, such that $f(0, 0) = 0$. Consider the control system

$$\dot{x} = f(x, u). \quad (4)$$

The Brockett system (1) investigated in this paper is of the form (4).

The hybrid feedback laws under consideration admit the following description (see [28, 6])

$$u = k(x, s_d), \quad s_d = k_d(x, s_d^-), \quad (5)$$

where s_d evolves in the finite set $\{1, 2\}$, the function $k : \mathbb{R}^n \times \{1, 2\} \rightarrow \mathbb{R}^m$ is a continuous function of x , for each fixed s_d , and $k_d : \mathbb{R}^n \times \{1, 2\} \rightarrow \{1, 2\}$ is a function. The notation s_d^- stands, at this stage only formally, for

$$s_d^-(t) = \lim_{s < t} s_d(s). \quad (6)$$

The set $\{1, 2\}$ is endowed with the discrete topology, *i.e.* every set is an open set. The above controller is hybrid, due to the presence of the discrete dynamics of s_d . It gives rise to a non-classical ordinary differential equation describing the dynamics of the closed-loop system.

We next recall the notion of robustness to a small noise (see [26]). Let $L_{loc}^\infty(\mathbb{R}^n \times [0, +\infty); \mathbb{R}^n)$ denote the set of essentially locally bounded functions, with values in \mathbb{R}^n .

Consider two functions e and d satisfying the following *regularity assumptions*:

$$\begin{aligned} e(\cdot, \cdot), d(\cdot, \cdot) &\in L_{loc}^\infty(\mathbb{R}^n \times [0, +\infty); \mathbb{R}^n), \\ e(\cdot, t), d(\cdot, t) &\in C^0(\mathbb{R}^n, \mathbb{R}^n), \quad \forall t \in [0, +\infty). \end{aligned} \quad (7)$$

We introduce these functions as a measurement noise e and an external disturbance d , and define the perturbed system¹ with u given by (5), by

$$\begin{aligned} \dot{x}(t) &= f(x(t), k(x(t) + e(x(t), t), s_d(t))) + d(x(t), t), \\ s_d(t) &= k_d(x(t) + e(x(t), t), s_d^-(t)). \end{aligned} \quad (8)$$

The notion of a solution of such a hybrid perturbed system has been well-studied in the literature (see *e.g.* [6, 7, 15, 28, 22, 23]). To be self-contained,

¹ we can also consider an actuator noise (see *e.g.* [14, 20]).

we recall the definition of a solution of (8) and we introduce a non-empty set \mathcal{RC} strictly contained in $\mathbb{R}^n \times \{1, 2\}$.

Definition 1 *Given $T > 0$ and $(x_0, s_0) \in \mathbb{R}^n \times \{1, 2\}$, we say that (x, s_d) is a solution of (8) on $[0, T)$, starting from (x_0, s_0) , if the following conditions hold:*

- *the map x is absolutely continuous on $[0, T)$;*
- *there holds, for almost every $t \in [0, T)$,*

$$\dot{x}(t) = f(x(t), k(x(t) + e(x(t), t), s_d(t))) + d(x(t), t);$$

- *for every $t \in [0, T)$ such that $(x(t), s_d(t)) \in \mathcal{RC}$, the map s_d is right-continuous at t ;*
- *for every $t \in (0, T)$ such that $s_d^-(t)$ exists, one has*

$$s_d(t) = k_d(x(t) + e(x(t), t), s_d^-(t)); \quad (9)$$

- *there holds $x(0) = x_0$, and $s_d(0) = k_d(x_0 + e(x_0, 0), s_0)$.*

We next define the concept of stabilization of (4) by a minimal time hybrid feedback law sharing a robustness property with respect to measurement noises and external disturbances. The usual Euclidean norm in \mathbb{R}^n is denoted by $|\cdot|$. Recall that a function of class \mathcal{K}_∞ is a function $\delta: [0, +\infty) \rightarrow [0, +\infty)$ which is continuous, increasing, satisfying $\delta(0) = 0$ and $\lim_{R \rightarrow +\infty} \delta(R) = +\infty$.

Definition 2 *Let $\rho: \mathbb{R}^n \rightarrow \mathbb{R}$ be a continuous function, which is positive outside 0. We say that the completeness assumption holds for ρ if, for all*

(e, d) satisfying the regularity assumptions (7) and

$$\sup_{[0, +\infty)} |e(x, \cdot)| \leq \rho(x), \text{esssup}_{[0, +\infty)} |d(x, \cdot)| \leq \rho(x), \forall x \in \mathbb{R}^n, \quad (10)$$

for all $(x_0, s_0) \in \mathbb{R}^n \times \{1, 2\}$, there exists a maximal solution of (8) on $[0, +\infty)$, starting from (x_0, s_0) .

Definition 3 We say that the uniform finite time convergence property holds if there exists a continuous function $\rho : \mathbb{R}^n \rightarrow \mathbb{R}$, positive outside 0, satisfying the completeness assumption, and if there exists a function δ of class \mathcal{K}_∞ , so that, for every $R > 0$, there exists $\tau > 0$ such that, for all functions e, d satisfying the regularity assumptions (7) and inequalities (10) for this function ρ , for every $x_0 \in \mathbb{R}^n$, $|x_0| \leq R$, and every $s_0 \in \{1, 2\}$, the maximal solution (x, s_d) of (8), starting from (x_0, s_0) , satisfies

$$|x(t)| \leq \delta(R), \forall t \geq 0, \quad (11)$$

and

$$x(t) = 0, \forall t \geq \tau. \quad (12)$$

Definition 4 The origin is said to be a semi-globally minimal time robustly stabilizable equilibrium for the system (4) if, for every $\varepsilon > 0$ and every compact subset $K \subset \mathbb{R}^n$, there exists a hybrid feedback law $(u, k_d) : \mathbb{R}^n \times \{1, 2\} \rightarrow \mathbb{R}^m \times \{1, 2\}$ satisfying the constraint

$$\|k(x, s_d)\| \leq 1, \quad (13)$$

where $\|\cdot\|$ stands for the Euclidian norm in \mathbb{R}^m , such that:

- the uniform finite time convergence property holds;

– there exists a continuous function $\rho_{\varepsilon,K} : \mathbb{R}^n \rightarrow \mathbb{R}$, positive outside 0, such that, for all functions e, d satisfying the regularity assumptions (7) and inequalities (10) for $\rho = \rho_{\varepsilon,K}$, for every $x_0 \in K$, the maximal solution of (8), starting from x_0 , reaches the origin within time $T(x_0) + \varepsilon$, where $T(x_0)$ denotes the minimal time to steer the system (4) from x_0 to the origin, with the constraint $\|u\| \leq 1$.

3 Main result

Theorem 1 *The origin is a semi-globally minimal time robustly stabilizable equilibrium for the system (1) with the constraint (3).*

Remark 1 Some observations are in order.

1. An explicit expression for the hybrid feedback law (u, k_d) is given in Section 5.
2. Note that the problem of *global* robust minimal time stabilization (*i.e.* $K = \mathbb{R}^3$ in Definition 4) cannot be achieved because measurement noises may then accumulate and slow down the solution reaching the origin (compare with [8]). However, we provide a *globally* asymptotically stabilizing hybrid controller, in the sense that the constant $R > 0$ of the Definition 3 can be arbitrarily large.
3. Note that the conclusion of Theorem 1 does not hold if, in (10), the supremum *sup* is relaxed by *esssup* (see [20, Theorem 4.2], where it is proved, in an analogous situation, that there exists a measurement noise

e satisfying $\text{esssup } |e| = 0$, $\text{sup } |e| \neq 0$, such that the origin of the perturbed closed-loop system is not an attractive equilibrium).

Intuitively, the strategy is as follows. For $x \in \mathbb{R}^3$, let $T(x)$ denote the minimal time needed to steer the system (1) from x to the origin, with the constraint (3). The corresponding minimal time feedback controller, called *local controller*, happens to be continuous (even analytic) on $\mathbb{R}^n \setminus \{x_1 = x_2 = 0\}$. It is therefore necessary to use another controller, called *global controller*, in a neighborhood Ω of the line $\{x_1 = x_2 = 0\}$. More precisely, Ω will be constructed so as to be cylindric around this line, and conic near the origin (see Fig. 4 further). In this neighborhood, we define an adequate switching strategy. Notice that Ω is arbitrarily thin, and thus the time ε needed for the traversing of Ω is arbitrarily small, uniformly with respect to the initial condition. Therefore, starting from an initial point x , the time needed to join the origin, using this hybrid strategy, is equal to $T(x) + \varepsilon$.

The rest of the paper is organized as follows. We define the local controller in Section 4.1 and the global one in Section 4.2. The switching strategy between these feedback laws by means of a hysteresis is explained in Section 5. Theorem 1 is proved in Section 6.

4 The components of the hysteresis

4.1 The local controller

In this section, we define and compute the *local controller*, and give some properties of the Carathéodory solutions of (1) with this feedback law.

Consider the Brockett system (1). It is a standard fact that the minimal time problem for the system (1), with the constraint (3), is equivalent to the *sub-Riemannian problem* in \mathbb{R}^3 associated to the vector fields f_1 and f_2 (see for instance [5]), and moreover, the minimal time $T(x)$ needed to steer the origin to a point $x \in \mathbb{R}^3$ is equal to the sub-Riemannian distance of x to the origin. Using this fact, the function T may be computed explicitly, and we recall the following result of [4].

Proposition 1 *Consider the minimal time problem for the system (1) with the constraint (3). The minimal time $T(x)$ needed to steer a point $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ to the origin is given by*

$$T(x_1, x_2, x_3) = \frac{\theta}{\sqrt{\theta + \sin^2 \theta - \sin \theta \cos \theta}} \sqrt{x_1^2 + x_2^2 + 2|x_3|}, \quad (14)$$

where $\theta = \theta(x_1, x_2, x_3)$ is the unique solution in $[0, \pi)$ of

$$\frac{\theta - \sin \theta \cos \theta}{\sin^2 \theta} (x_1^2 + x_2^2) = 2|x_3|. \quad (15)$$

Moreover, the function T is continuous on \mathbb{R}^3 , and is analytic outside the line $x_1 = x_2 = 0$.

Remark 2 The function g , defined by

$$g(\theta) = \frac{\theta - \sin \theta \cos \theta}{\sin^2 \theta}, \quad (16)$$

for $\theta \in [0, \pi)$, with the agreement that $g(0) = 0$, is a monotone increasing diffeomorphism of $(0, \pi)$ onto $(0, +\infty)$. For every $\theta \in [0, \pi)$, define

$$h(\theta) = \frac{\theta}{\sqrt{\theta + \sin^2 \theta - \sin \theta \cos \theta}},$$

with the agreement that $h(0) = 1$ (see Fig. 1).

Fig. 1 The functions g and h .

For every $s \in \mathbb{R}$, set $F(s) = h \circ g^{-1}(s)$. Then, there holds, outside the line $x_1 = x_2 = 0$,

$$T(x_1, x_2, x_3) = F\left(\frac{2|x_3|}{x_1^2 + x_2^2}\right) \sqrt{x_1^2 + x_2^2 + 2|x_3|}.$$

It can be checked that T is indeed analytic outside the line $x_1 = x_2 = 0$, even though it is not immediate from this expression (see [4]).

Remark 3 Along the line $x_1 = x_2 = 0$, there holds

$$T(0, 0, x_3) = \sqrt{2\pi|x_3|}.$$

The singular set of the function T , *i.e.* the set where T is not C^1 , is the line $x_1 = x_2 = 0$ in \mathbb{R}^3 . More precisely, the gradients $\partial T / \partial x_i$, $i = 1, 2$,

are discontinuous at every point $(0, 0, x_3)$, $x_3 \neq 0$. In the context of sub-Riemannian geometry, this singular line can be interpreted as a *cut-locus*.

Actually, for every $x_3 \neq 0$, there exists an infinite number of optimal trajectories steering the origin to the point $(0, 0, x_3)$, given by the set of curves

$$\begin{aligned} x_1(t) &= \sqrt{\frac{|x_3|}{2\pi}} (\sin(2\pi t + \varphi) - \sin \varphi), \\ x_2(t) &= \sqrt{\frac{|x_3|}{2\pi}} (\cos(2\pi t + \varphi) - \cos \varphi), \\ x_3(t) &= x_3 t - \frac{|x_3|}{2\pi} \sin(2\pi t), \end{aligned} \tag{17}$$

for $t \in [0, 1]$ and $\varphi \in [0, 2\pi]$ (see for instance [4]).

Remark 4 Using the previous notations, there holds, for every $x = (x_1, x_2, x_3) \in \mathbb{R}^3$,

$$T(x_1, x_2, x_3) = h(\theta) \sqrt{x_1^2 + x_2^2 + |x_3|}, \tag{18}$$

$$= \left(\theta \frac{\cos \theta}{\sin \theta} (x_1^2 + x_2^2) + 2\theta |x_3| \right)^{\frac{1}{2}}, \tag{19}$$

$$= \frac{\theta}{\sin \theta} \sqrt{x_1^2 + x_2^2}, \tag{20}$$

where $\theta = \theta(x_1, x_2, x_3)$ is the unique solution in $[0, \pi)$ of (15).

A level set $\{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid T(x_1, x_2, x_3) = r\}$, where $r > 0$, is drawn on Fig. 2. In the context of sub-Riemannian geometry, it represents the sub-Riemannian sphere centered at the origin, with radius r , in the Heisenberg case (see [5]). Observe that it is axial symmetric, with respect to the axis $(0x_3)$.

On Fig. 3 are drawn intersections of different level sets of T with a plane containing the axis $(0x_3)$.

Fig. 2 Level set $\{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid T(x_1, x_2, x_3) = r\}$.

Remark 5 There exists a *one-parameter group of dilations*

$$\delta_\lambda : (x_1, x_2, x_3) \mapsto (\lambda x_1, \lambda x_2, \lambda^2 x_3),$$

so that

$$T(\delta_\lambda x) = |\lambda|T(x),$$

for every $x \in \mathbb{R}^3$ (see [5]). This property can be observed on Fig. 3.

It follows from the Pontryagin maximum principle and the Hamilton-Jacobi theory (see [19]) that the minimal time control functions, steering a point $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ to the origin, are given by the closed-loop formula

$$\begin{aligned} u_1(x) &= -\frac{1}{2} \langle \nabla T(x), f_1(x) \rangle = -\frac{1}{2} \left(\frac{\partial T}{\partial x_1} + x_2 \frac{\partial T}{\partial x_3} \right), \\ u_2(x) &= -\frac{1}{2} \langle \nabla T(x), f_2(x) \rangle = -\frac{1}{2} \left(\frac{\partial T}{\partial x_2} - x_1 \frac{\partial T}{\partial x_3} \right), \end{aligned} \quad (21)$$

provided T is C^1 at x . In particular, this holds outside the line $x_1 = x_2 = 0$.

Fig. 3 Intersection of different level sets with a vertical plane.

Outside this line, the smoothness of this optimal controller ensures a robustness property of the stability. A switching strategy is then necessary between this optimal controller and another controller which has to be continuous in a neighborhood of the line $x_1 = x_2 = 0$. This latter controller, denoted u_g , is called *global controller*, and is defined in Section 4.2, whereas the optimal one, denoted u_l , is called the *local controller*. The switching strategy is achieved by adding a dynamical discrete variable s_d and using a hybrid feedback law (see Section 5).

Below, we give an explicit expression of the optimal controller (local controller), using the following lemma.

Lemma 1 *For every $x = (x_1, x_2, x_3) \in \mathbb{R}^3$ such that $x_1^2 + x_2^2 \neq 0$, there holds*

$$\frac{\partial T}{\partial x_i} = \cos \theta \frac{x_i}{\sqrt{x_1^2 + x_2^2}}, \quad i = 1, 2, \quad \frac{\partial T}{\partial x_3} = \text{sign}(x_3) \sin \theta,$$

where $\theta = \theta(x_1, x_2, x_3)$ is the unique solution in $[0, \pi)$ of (15).

Remark 6 Notice that, if $x_1^2 + x_2^2 \neq 0$, then $\theta(x_1, x_2, 0) = 0$, and hence

$$\frac{\partial T}{\partial x_3}(x_1, x_2, 0) = 0.$$

Corollary 1 *The minimal time controller $u_l = (u_{l1}, u_{l2})$, steering a point*

$x = (x_1, x_2, x_3) \in \mathbb{R}^3$ *such that $x_1^2 + x_2^2 \neq 0$ to the origin, writes*

$$\begin{aligned} u_{l1}(x) &= -\frac{1}{2} \left(\frac{x_1}{\sqrt{x_1^2 + x_2^2}} \cos \left(g^{-1} \left(\frac{2|x_3|}{x_1^2 + x_2^2} \right) \right) + \text{sign}(x_3) x_2 \sin \left(g^{-1} \left(\frac{2|x_3|}{x_1^2 + x_2^2} \right) \right) \right), \\ u_{l2}(x) &= -\frac{1}{2} \left(\frac{x_2}{\sqrt{x_1^2 + x_2^2}} \cos \left(g^{-1} \left(\frac{2|x_3|}{x_1^2 + x_2^2} \right) \right) - \text{sign}(x_3) x_1 \sin \left(g^{-1} \left(\frac{2|x_3|}{x_1^2 + x_2^2} \right) \right) \right), \end{aligned} \quad (22)$$

where the function g is defined by (16).

For all $M > 0$ and $r > 0$, we introduce the subset of \mathbb{R}^3

$$\Omega_{M,r} = \{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid x_1^2 + x_2^2 \leq \min(r, M|x_3|)\}, \quad (23)$$

and denote its complement in \mathbb{R}^3 by $\Gamma_{M,r}$. Near the origin, $\Omega_{M,r}$ is a cone, otherwise it is a cylinder around the axis $(0x_3)$ (see Fig. 4).

The following lemma follows immediately from the behavior of the optimal flow (see formulas (17) in Remark 3).

Lemma 2 *There exist $M_0 > 0$ and $r_0 > 0$ such that, for all M and r satisfying $0 < M < M_0$ and $0 < r < r_0$, the subset $\Gamma_{M,r}$ is invariant by the feedback optimal controller u_l .*

Now this local controller has been defined, we investigate the robustness properties of the system (1) in closed-loop with this controller. Given $e, d : \mathbb{R}^3 \times [0, +\infty) \rightarrow \mathbb{R}^3$, the perturbed closed-loop system under consideration

Fig. 4 Shape of $\Omega_{M,r}$.

in this section is of the form

$$\dot{x}(t) = f(x(t), u_l(x(t) + e(x(t), t))) + d(x(t), t). \quad (24)$$

Below, a robust version of Lemma 2 is stated for every noise vanishing along the discontinuous set of the local controller. More precisely, all properties needed to state our main result are summarized in the following lemma.

Lemma 3 *There exist a continuous function $\rho_l : \mathbb{R} \rightarrow \mathbb{R}$, positive outside 0, and a continuous function $\delta_l : [0, +\infty) \rightarrow [0, +\infty)$ of class \mathcal{K}_∞ , such that:*

- Stability: *for all M and r satisfying $0 < M < M_0$ and $0 < r < r_0$, all $e, d : \mathbb{R}^3 \times [0, +\infty) \rightarrow \mathbb{R}^3$ satisfying the regularity assumptions (7) and*

$$\sup_{[0, +\infty)} |e(x, \cdot)| \leq \rho_l(x_1^2 + x_2^2), \quad \text{esssup}_{[0, +\infty)} |d(x, \cdot)| \leq \rho_l(x_1^2 + x_2^2), \quad \forall x \in \mathbb{R}^3, \quad (25)$$

and for every $x_0 \in \Gamma_{M,r}$, there exists a unique maximal Carathéodory solution $x(\cdot)$ of (24) on $[0, +\infty)$, starting from x_0 , satisfying $x(t) \in \Gamma_{M,r}$, for every $t > 0$;

- Finite-time convergence: for every $R > 0$, there exists $\tau > 0$ such that, for all $e, d: \mathbb{R}^3 \times [0, +\infty) \rightarrow \mathbb{R}^3$ satisfying the regularity assumptions (7) and (25), for every x_0 in \mathbb{R}^3 with $|x_0| \leq R$, and every maximal solution $x(\cdot)$ of (24) starting from x_0 , one has

$$|x(t)| \leq \delta_l(R), \quad \forall t \geq 0, \quad (26)$$

$$x(t) = 0, \quad \forall t \geq \tau, \quad (27)$$

and

$$\|u_l(x(t))\| \leq 1, \quad \forall t \geq 0; \quad (28)$$

- Optimality: for every $\varepsilon > 0$, and every compact subset $K \subset \mathbb{R}^3$, there exists a continuous function $\rho_{\varepsilon,K}: \mathbb{R}^3 \rightarrow \mathbb{R}$, positive outside 0, such that, for all $e, d: \mathbb{R}^3 \times [0, +\infty) \rightarrow \mathbb{R}^3$ satisfying the regularity assumptions (7) and

$$\sup_{[0, +\infty)} |e(x, \cdot)| \leq \min(\rho_l(x_1^2 + x_2^2), \rho_{\varepsilon,K}(x)), \quad \forall x \in \mathbb{R}^3, \quad (29)$$

$$\text{esssup}_{[0, +\infty)} |d(x, \cdot)| \leq \min(\rho_l(x_1^2 + x_2^2), \rho_{\varepsilon,K}(x)), \quad \forall x \in \mathbb{R}^3,$$

and for every $x_0 \in K \cap \Gamma_{M,r}$, the solution of (24), starting from x_0 , reaches the origin within time $T(x_0) + \varepsilon$.

Proof Since Carathéodory conditions hold for the system (24), the existence of a unique forward Carathéodory solution of (24), for every initial condition, is ensured. Note that, since the controller u_l is the minimal time control

steering x to the origin under the constraint (3), the inequality (28) holds. Since the local controller u_l defined by (22) is continuous on $\mathbb{R}^3 \setminus \{x_1 = x_2 = 0\}$, Lemma 2 implies the existence of $\rho_l : [0, +\infty) \rightarrow [0, +\infty)$. The last part of the result follows from (21) and from the continuity of solutions with respect to disturbances.

4.2 The global controller

In this section we define the second component of the hysteresis, called *global controller* and denoted u_g . Moreover we give some basic properties of the Carathéodory solutions of the closed-loop system (4) with such a control law u_g .

Let us consider the feedback law

$$u_{g1}(x) = 1, \quad u_{g2}(x) = 0. \quad (30)$$

The closed-loop system considered in this section is of the form

$$\dot{x}(t) = f(x(t), u_g(x(t) + e(x(t), t))) + d(x(t), t). \quad (31)$$

The following result, whose proof is obvious using (30), states that the trajectories of the system (31) enter the region $\Gamma_{M,r}$ in finite time, while remaining bounded up to this time.

Lemma 4 *With the notations of Lemma 3, there exists a continuous function $\rho_g : \mathbb{R}^3 \rightarrow \mathbb{R}$ satisfying*

$$\rho_g(x) > 0, \quad \forall x \neq 0, \quad (32)$$

such that, for every initial condition, the perturbed system (31), where e and d are two arbitrary functions satisfying the regularity assumptions (7) and inequalities (10) with $\rho = \rho_g$, admits a unique Carathéodory solution, defined for all $t \geq 0$.

Moreover there exists a function δ_g of class \mathcal{K}_∞ such that, for all $R > 0$, and M and r satisfying $0 < M < M_0$ and $0 < r < r_0$, there exists a time $\tau_g = \tau_g(M, r, R)$ such that all Carathéodory solution x of (31) starting from x_0 , with $|x_0| \leq R$, satisfies

$$|x(t)| \leq \delta_g(R), \quad \forall t \leq \tau_g, \quad (33)$$

$$x(t) \in \Gamma_{M,r}, \quad \forall t \geq \tau_g, \quad (34)$$

and

$$\|u_g(x(t))\| \leq 1, \quad \forall t \geq 0. \quad (35)$$

5 Definition of the hybrid controller

In this section we define the hybrid controller by using a hysteresis to connect both controllers defined in Sections 4.1 and 4.2.

For every $i \in \{1, \dots, 6\}$, let M_i and r_i so that

$$0 < M_6 < M_5 < M_4 < M_3 < M_2 < M_1 < M_0, \quad (36)$$

$$0 < r_6 < r_5 < r_4 < r_3 < r_2 < r_1 < r_0.$$

For the sake of simplicity, in what follows we set $\Gamma_i = \Gamma_{M_i, r_i}$ and $\Omega_i = \Omega_{M_i, r_i}$, for every $i \in \{1, \dots, 6\}$. The hybrid controller (k, k_d) is defined

using the following hysteresis between u_l and u_g on Γ_5 and Γ_2 :

$$\begin{aligned} k : \mathbb{R}^3 \times \{1, 2\} &\rightarrow \mathbb{R}^2 \\ (x, s_d) &\mapsto u_l(x) \text{ if } s_d = 1, \\ &u_g(x) \text{ if } s_d = 2, \end{aligned} \quad (37)$$

and

$$\begin{aligned} k_d : \mathbb{R}^3 \times \{1, 2\} &\rightarrow \{1, 2\} \\ (x, s_d) &\mapsto 1 \quad \text{if } x \in \Gamma_2, \\ &s_d \quad \text{if } x \in \Gamma_5 \setminus \Gamma_2, \\ &2 \quad \text{if } x \notin \Gamma_5 \cup \{0\}. \end{aligned} \quad (38)$$

6 Properties of the solutions and proof of Theorem 1

6.1 Properties of the solutions

In this section, we study some properties of the solutions of the perturbed system (8) in closed-loop with the hybrid controller (37) and (38). Let $\varepsilon > 0$ and K be a compact subset of \mathbb{R}^n . We set²

$$\mathcal{RC} = \mathbb{R}^3 \times \{1, 2\} \setminus \left((\text{clos}(\Gamma_3) \setminus \Gamma_1) \times \{2\} \cup (\text{clos}(\Gamma_6) \setminus \Gamma_4) \times \{1\} \right) \quad (39)$$

(see [21] for a similar but simpler situation). Let $\rho : \mathbb{R}^3 \rightarrow \mathbb{R}$ be a continuous function, positive outside 0, so that:

- for every $x \in \Gamma_6$,

$$\rho(x) \leq \min(\rho_l(x_1^2 + x_2^2), \rho_{\varepsilon, K}(x)), \quad (40)$$

² For a given subset Ω of \mathbb{R}^n , the closure, the interior and the boundary of Ω are denoted by $\text{clos}(\Omega)$, $\text{int}(\Omega)$ and $\partial\Omega$, respectively.

and, for every $x \in \mathbb{R}^3 \setminus \Gamma_1$,

$$\rho(x) \leq \rho_g(x), \quad (41)$$

where ρ_l , $\rho_{\varepsilon,K}$ and ρ_g are defined in Lemma 3 and Lemma 4;

- the following implication holds, for every $i \in \{1, \dots, 5\}$, and every $e \in \mathbb{R}^3$ so that $|e| \leq \rho(x)$,

$$x + e \in \Gamma_i \Rightarrow x \in \Gamma_{i+1}; \quad (42)$$

- the following implication holds, for every $i \in \{2, \dots, 6\}$, and every $e \in \mathbb{R}^3$ so that $|e| \leq \rho(x)$,

$$x + e \notin \Gamma_i \Rightarrow x \notin \Gamma_{i-1}. \quad (43)$$

Let e and d be two functions satisfying the regularity assumptions (7) and (10). We now state, without proof, a series of four preliminary results, which are instrumental to prove Theorem 1. They concern general properties of solutions of hybrid systems, and the arguments are conceptually analogous to those of [21, 23].

Lemma 5 *For all $(x_0, s_0) \in \mathbb{R}^3 \times \{1, 2\}$, there exists a solution of (8), in closed-loop with (37) and (38), starting from (x_0, s_0) .*

To describe further properties of the trajectories of the considered system, we recall the definition of a *switch*.

Definition 5 *A map $s_d: [0, T) \rightarrow \{1, 2\}$ is said to have a switch at time t if s_d is not continuous at t .*

Let (x, s_d) be a solution of (8) in closed-loop with (37) and (38). To address the problem of locating the points where s_d may have a switch, consider the sets

$$s_d^p(t) = \{s \mid \exists t_n \in [t, T), t_n \xrightarrow[n \rightarrow \infty]{} t, s_d(t_n) \xrightarrow[n \rightarrow \infty]{} s\}, \quad (44)$$

$$s_d^m(t) = \{s \mid \exists t_n \in [t_0, t], t_n \xrightarrow[n \rightarrow \infty]{} t, s_d(t_n) \xrightarrow[n \rightarrow \infty]{} s\}, \quad (45)$$

for every t in $(0, T)$.

Lemma 6 *Let (x, s_d) be a solution of (8), in closed-loop with (37) and (38), such that s_d has a switch at time $t \in (0, T)$.*

- *If the switch is such that $2 \in s_d^m(t)$ and $1 \in s_d^p(t)$, then $x(t) \in \text{clos}(\Gamma_3) \setminus \Gamma_1$.*
- *If the switch is such that $1 \in s_d^m(t)$ and $2 \in s_d^p(t)$, then $x(t) \in \text{clos}(\Gamma_6) \setminus \Gamma_4$.*

Lemma 7 *Let (x, s_d) be a maximal solution of (8), in closed-loop with (37) and (38), defined on $[0, T)$. If $T < +\infty$, then $\limsup_{t \rightarrow T} |x(t)| = +\infty$.*

Lemma 8 *Let (x, s_d) be a maximal solution of (8), in closed-loop with (37) and (38), defined on $[0, T)$. Then $T = +\infty$, and only the following cases may occur:*

1. *there exists no switch, and x is a Carathéodory solution of (24) on $[0, +\infty)$, contained in Γ_6 ;*
2. *there exists a time σ in $(0, +\infty)$ such that*
 - *x is a Carathéodory solution of (31) on $[0, \sigma)$, and is not in Γ_1 ;*
 - *x is a Carathéodory solution of (24) on $[\sigma, +\infty)$, contained in Γ_6 ;*

3. there exist two switches σ_1 and σ_2 in $(0, +\infty)$ such that

- x is a Carathéodory solution of (24) on $[0, \sigma_1)$, contained in $\Gamma_6 \setminus \Gamma_1$;
- x is a Carathéodory solution of (31) on $[\sigma_1, \sigma_2)$, and is not in Γ_1 ;
- x is a solution of (24) on $[\sigma_2, +\infty)$, contained in Γ_6 .

Remark 7 As a consequence of Lemma 8, every solution of the perturbed system switches at most two times.

6.2 Proof of Theorem 1

Let ε be a positive real number, and K be a compact subset of \mathbb{R}^n .

Consider $M_0 > 0$ and $r_0 > 0$ given by Lemma 2, M_i, r_i for every $i \in \{1, \dots, 6\}$ satisfying (36), and $\rho: \mathbb{R}^3 \rightarrow \mathbb{R}$ satisfying (40)-(43). Up to reducing M_0 and r_0 , we assume that

every solution of (31) starting from Ω_6 enters Γ_0 in time less than ε ,

(46)

and

every solution of (24) starting from Γ_6 enters Γ_1 in time less than ε . (47)

The proof splits into three parts.

Completeness

Existence of solutions follows from Lemma 5, and maximality from Lemma 8.

Uniform finite time convergence

Let $R > 0$. Consider perturbations $e, d : \mathbb{R}^3 \times [0, +\infty) \rightarrow \mathbb{R}^3$ satisfying the regularity assumptions (7) and (10), for every $x \in \mathbb{R}^3$. Let $x_0 \in \mathbb{R}^3$ such that $|x_0| < R$, let $s_0 \in \{1, 2\}$, and (x, s_d) be the corresponding solution of (8), in closed-loop with (37) and (38), starting from (x_0, s_0) , and defined on $[0, +\infty)$.

As a consequence of Lemmas 3, 4 and 8, we have, for every $t \geq 0$,

$$|x(t)| \leq \max(\delta_l(R), \delta_l(\delta_g(R)), \delta_l(\delta_g(\delta_l(R)))),$$

i.e.

$$|x(t)| \leq \delta_l(\delta_g(\delta_l(R))). \quad (48)$$

Thus (11) holds.

Consider now $\tau = \pi(\delta_l(\delta_g(\delta_l(R))))$, where π is the time defined in Lemma 3. From Lemmas 3, 4 and 8, we get, for every $t \geq \tau$,

$$x(t) = 0.$$

Minimal time

Let $x_0 \in K$. The solution of system (8), in closed-loop with (37) and (38), starting from x_0 , switches at most two times and, using (46), (47), and Lemma 8, enters F_1 (let say, at a point x_1) in time less than 2ε . After the last switch, Lemma 3 applies, and thus, the solution reaches the origin at a time less than $T(x_1) + \varepsilon$. Since the gradient of T is uniformly bounded (see Lemma 1), then, up to reducing r_0 , we get $T(x_0) \leq T(x_1) + \varepsilon$. As

a conclusion, the solution reaches the origin in time less than $T(x_0) + 4\varepsilon$.

Theorem 1 is proved.
