Slow movement of random walk
in random environment on a regular tree

by
Yueyun Hu and Zhan Shi

Université Paris XIII & Université Paris VI

Summary. We consider a recurrent random walk in random environment on a regular tree. Under suitable general assumptions upon the distribution of the environment, we show that the walk exhibits an unusual slow movement: the order of magnitude of the walk in the first $n$ steps is $(\log n)^{3/5}$.

Keywords. Random walk in random environment, slow movement, tree, branching random walk.

2000 Mathematics Subject Classification. 60K37, 60G50, 60J80.

1 Introduction

Let $T$ be a rooted $b$-ary tree, with $b \geq 2$. Let $\omega := (\omega(x,y), x, y \in T)$ be a collection of non-negative random variables such that $\sum_{y \in T} \omega(x,y) = 1$ for any $x \in T$. Given $\omega$, we define a Markov chain $X := (X_n, n \geq 0)$ on $T$ with $X_0 = e$ and

$$P_\omega(X_{n+1} = y \mid X_n = x) = \omega(x,y).$$

The process $X$ is called random walk in random environment (or simply RWRE) on $T$. (By informally taking $b = 1$, $X$ would become a usual RWRE on the half-line $\mathbb{Z}_+$.)

We refer to page 106 of Pemantle and Peres [14] for a list of motivations to study tree-valued RWRE. For a close relation between tree-valued RWRE and Mandelbrot’s multiplicative cascades, see Menshikov and Petritis [14].
We use $P$ to denote the law of $\omega$, and the semi-product measure $P(\cdot) := \int P(\cdot) P(d\omega)$ to denote the distribution upon average over the environment.

Some basic notation of the tree is in order. Let $e$ denote the root of $T$. For any vertex $x \in T \setminus \{e\}$, let $\overline{x}$ denote the parent of $x$. As such, each vertex $x \in T \setminus \{e\}$ has one parent $\overline{x}$ and $b$ children, whereas the root $e$ has $b$ children but no parent. For any $x \in T$, we use $|x|$ to denote the distance between $x$ and the root $e$: thus $|e| = 0$, and $|x| = |\overline{x}| + 1$.

We define 

$$A(x) := \frac{\omega(\overline{x}, x)}{\omega(x, \overline{x})}, \quad x \in T, \ |x| \geq 2,$$

where $\overline{\overline{x}}$ denotes the parent of $\overline{x}$.

Following Lyons and Pemantle [14], we assume throughout the paper that $(\omega(x, \bullet))_{x \in T \setminus \{e\}}$ is a family of i.i.d. non-degenerate random vectors and that $(A(x), \ x \in T, \ |x| \geq 2)$ are identically distributed. We also assume the existence of $\varepsilon_0 > 0$ such that $\omega(x, y) \geq \varepsilon_0$ if either $x = \overline{\overline{y}}$ or $y = \overline{x}$, and $\omega(x, y) = 0$ otherwise; in words, $(X_n)$ is a nearest-neighbour walk, satisfying an ellipticity condition.

Let $A$ denote a generic random variable having the common distribution of $A(x)$ (for $|x| \geq 2$) defined in (1.1). Let 

$$p := \inf_{t \in [0,1]} E(A^t).$$

An important criterion of Lyons and Pemantle [14] says that with $P$-probability one, the walk $(X_n)$ is recurrent or transient, according to whether $p \leq \frac{1}{b}$ or $p > \frac{1}{b}$. It is, moreover, positive recurrent if $p < \frac{1}{b}$. Later, Menshikov and Petritis [16] proved that the walk is null recurrent if $p = \frac{1}{b}$.

Throughout the paper, we write 

$$X_n^* := \max_{0 \leq k \leq n} |X_k|, \quad n \geq 0.$$

In the positive recurrent case $p < \frac{1}{b}$, $\frac{X_n^*}{\log n}$ converges $P$-almost surely to a constant $c \in (0, \infty)$ whose value is known, see [9].

The null recurrent case $p = \frac{1}{b}$ is more interesting. It turns out that the behaviour of the walk depends also on the sign of $\psi'(1)$, where 

$$\psi(t) := \log E \left( A^t \right), \quad t \geq 0.$$

In [14], we proved that if $p = \frac{1}{b}$ and $\psi'(1) < 0$, then 

$$\lim_{n \to \infty} \frac{\log X_n^*}{\log n} = 1 - \frac{1}{\min\{\kappa, 2\}}, \quad P\text{-a.s.}$$
where $\kappa := \inf\{t > 1 : \mathbb{E}(A^t) = \frac{1}{b}\} \in (1, \infty]$, with $\inf \emptyset := \infty$.

The delicate case $p = \frac{1}{b}$ and $\psi'(1) \geq 0$ was left open, and is studied in the present paper. See Figure 1.

![Figure 1: Case $\psi'(1) = 0$ and case $\psi'(1) > 0$ with $\theta$ defined in (2.5).](image)

We will see in Remark 2.3 that the case $\psi'(1) > 0$ boils down to the case $\psi'(1) = 0$ via a simple transformation of the distribution of the random environment. As is pointed out by Biggins and Kyprianou [3] in the study of Mandelbrot’s multiplicative cascades, the case $\psi'(1) = 0$ is likely to be “both subtle and important”.

The following theorem reveals an unusual slow regime for the walk.

**Theorem 1.1** If $p = \frac{1}{b}$ and if $\psi'(1) \geq 0$, then there exist constants $0 < c_1 \leq c_2 < \infty$ such that

\[
\liminf_{n \to \infty} \frac{X_n^*}{(\log n)^3} \leq \limsup_{n \to \infty} \frac{X_n^*}{(\log n)^3} \leq \frac{c_2}{\mathbb{P} \text{-a.s.}}.
\]

**Remark 1.2** (i) Theorem 1.1 somehow reminds of Sinai’s result ([21]) of slow movement of recurrent one-dimensional RWRE, whereas (1.4) is a (weaker) analogue of the Kesten–Kozlov–Spitzer characterization ([10]) of sub-diffusive behaviours of transient one-dimensional RWRE.

(ii) It is interesting to note that tree-valued RWRE possesses both regimes (slow movement and sub-diffusivity) in the recurrent case.

(iii) We mention an important difference between Theorem 1.1 and Sinai’s result. If $(Y_n, n \geq 0)$ is a recurrent one-dimensional RWRE, Sinai’s theorem says that $\frac{Y_n}{(\log n)^3}$ converges in distribution (under $\mathbb{P}$) to a non-degenerate limit law, whereas it is known (see [8])
that
\[ \limsup_{n \to \infty} \frac{Y_n^*}{(\log n)^2} = \infty, \quad \liminf_{n \to \infty} \frac{Y_n^*}{(\log n)^2} = 0, \quad \mathbb{P}\text{-a.s.,} \]
where \( Y_n^* := \max_{0 \leq k \leq n} |Y_k| \).

(iv) It is not clear to us whether \( \frac{X_n^*}{(\log n)^{3/2}} \) converges \( \mathbb{P}\)-almost surely.

(v) We believe that \( \frac{|X_n^*|}{(\log n)^{3/2}} \) would converge in distribution under \( \mathbb{P} \).
\( \square \)

In Section 2, we describe the method used to prove Theorem 1.1. In particular, we introduce an associate branching random walk, and prove an almost sure result for this branching random walk (Theorem 2.2) which may be of independent interest. (The two theorems are related to via Proposition 2.4.)

The organization of the proof of the theorems is described at the end of Section 2. We mention that Theorem 1.1 is proved in Section 6.

Throughout the paper, \( c \) (possibly with a subscript) denotes a finite and positive constant; we write \( c(\omega) \) instead of \( c \) when the value of \( c \) depends on the environment \( \omega \).

2 An associated branching random walk

For any \( m \geq 0 \), let
\[ T_m := \{ x \in T : |x| = m \}, \]
which stands for the \( m \)-th generation of the tree. For any \( n \geq 0 \), let
\[ \tau_n := \inf \{ i \geq 1 : X_i \in T_n \} = \inf \{ i \geq 1 : |X_i| = n \}, \]
the first hitting time of the walk at level \( n \) (whereas \( \tau_0 \) is the first return time to the root). We write
\[ \varrho_n := P_{\omega} \{ \tau_n < \tau_0 \}. \]
In words, \( \varrho_n \) denotes the (quenched) probability that the RWRE makes an excursion of height of at least \( n \).

An important step in the proof of Theorem 1.1 is the following estimate for \( \varrho_n \), in case \( \psi'(1) = 0 \):

**Theorem 2.1** Assume \( p = \frac{1}{b} \) and \( \psi'(1) = 0 \).

(i) There exist constants \( 0 < c_3 \leq c_4 < \infty \) such that \( \mathbb{P} \)-almost surely for all large \( n \),
\begin{equation}
\tag{2.1}
e^{-c_4 n^{1/3}} \leq \varrho_n \leq e^{-c_3 n^{1/3}}.
\end{equation}
There exist constants $0 < c_5 \leq c_6 < \infty$ such that for all large $n$,

\begin{equation}
\label{eq:2.2}
e^{-c_6 n^{1/3}} \leq \mathbb{E}(\varrho_n) \leq e^{-c_5 n^{1/3}}.
\end{equation}

It turns out that $\varrho_n$ is closely related to a branching random walk. But let us first extend the definition of $A(x)$ to all $x \in T \setminus \{e\}$.

For any $x \in T$, let $\{x_i\}_{1 \leq i \leq b}$ denote the set of the children of $x$. In addition of the random variables $A(x)$ ($|x| \geq 2$) defined in (1.1), let $(A(e_i), 1 \leq i \leq b)$ be a random vector independent of $(\omega(x, y), |x| \geq 1, y \in T)$, and distributed as $(A(x_i), 1 \leq i \leq b)$, for any $x \in T_m$ with $m \geq 1$. As such, $A(x)$ is well-defined for all $x \in T \setminus \{e\}$.

We now define the process $V = (V(x), x \in T)$ by $V(e) := 0$ and

\[
V(x) := - \sum_{z \in [e, x]} \log A(z), \quad x \in T \setminus \{e\}.
\]

It is clear that $V$ only depends on the environment $\omega$. In the literature, $V$ is often referred to as a branching random walk, see for example Biggins and Kyprianou [2].

We first state the main result of the section. Let

\begin{equation}
\label{eq:2.3}
\overline{V}(x) := \max_{z \in [e, x]} V(z),
\end{equation}

which stands for the maximum of $V$ over the path $[e, x]$.

**Theorem 2.2** If $p = \frac{1}{b}$ and if $\psi'(1) \geq 0$, then there exist constants $0 < c_7 \leq c_8 < \infty$ such that

\begin{equation}
\label{eq:2.4}
c_7 \leq \liminf_{n \to \infty} \frac{1}{n^{1/3}} \min_{x \in T_n} \overline{V}(x) \leq \limsup_{n \to \infty} \frac{1}{n^{1/3}} \min_{x \in T_n} \overline{V}(x) \leq c_8, \quad \mathbb{P}\text{-a.s.}
\end{equation}

**Remark 2.3** (i) We cannot replace $\min_{x \in T_n} \overline{V}(x)$ by $\min_{x \in T_n} V(x)$ in Theorem 2.2, in fact, it is proved by McDiarmid [13] that there exists a constant $c_9$ such that $\mathbb{P}$-almost surely for all large $n$, we have $\min_{x \in T_n} V(x) \leq c_9 \log n$.

---

1The values of $\omega$ at a finite number of edges are of no particular interest. Our choice of $(A(e_i), 1 \leq i \leq b)$ allows to make unified statements of $A(x), V(x)$, etc., without having to distinguish whether $|x| = 1$ or $|x| \geq 2$. 

5
(ii) If \((p = \frac{1}{b} \text{ and}) \psi'(1) < 0\), it is well-known (Hammersley [4], Kingman [11], Biggins [1]) that \(\frac{1}{n} \min_{x \in T_n} V(x)\) converges \(P\)-almost surely to a (strictly) positive constant whose value is known; thus \(\min_{x \in T_n} V(x)\) grows linearly in this case.

(iii) Only the case \(\psi'(1) = 0\) needs to be proved. Indeed, if \((p = \frac{1}{b} \text{ and}) \psi'(1) > 0\), then there exists a unique \(0 < \theta < 1\) such that

\[
\psi'(\theta) = 0, \quad E(A^\theta) = \frac{1}{b}.
\]

We define \(\tilde{A} := A^\theta\), \(\tilde{p} := \inf_{t \in [0, 1]} E(\tilde{A}^t)\) and \(\tilde{\psi}(t) := \log E(\tilde{A}^t), t \geq 0\). Clearly, we have

\[
\tilde{p} = \frac{1}{b}, \quad \tilde{\psi}'(1) = 0.
\]

Let \(\tilde{V}(x) := -\sum_{z \in \{e, x\}} \log \tilde{A}(z)\). Then \(V(x) = \frac{1}{b} \tilde{V}(x)\), which leads us to the case \(\psi'(1) = 0\).

\[\square\]

Here is the promised relation between \(\varrho_n\) and \(V\), for recurrent RWRE on \(T\).

**Proposition 2.4** If \((X_n)\) is recurrent, there exists a constant \(c_{10} > 0\) such that for any \(n \geq 1\),

\[
\varrho_n \geq \frac{c_{10}}{n} \exp \left(-\min_{x \in T_n} V(x)\right).
\]

**Proof of Proposition 2.4.** For any \(x \in T\), let

\[
T(x) := \inf \{i \geq 0 : X_i = x\},
\]

which is the first hitting time of the walk at vertex \(x\). By definition, \(\tau_n = \min_{x \in T_n} T(x)\), for \(n \geq 1\). Therefore,

\[
\varrho_n \geq \max_{x \in T_n} P_x \{T(x) < \tau_0\}.
\]

We now compute the (quenched) probability \(P_x \{T(x) < \tau_0\}\). We fix \(x \in T_n\), and define a random sequence \((\sigma_j)_{j \geq 0}\) by \(\sigma_0 := 0\) and

\[
\sigma_j := \inf \{k > \sigma_{j-1} : X_k \in [e, x]\} \backslash \{X_{\sigma_{j-1}}\}, \quad j \geq 1.
\]

(Of course, the sequence depends on \(x\).) Let

\[
Z_k := X_{\sigma_k}, \quad k \geq 0.
\]
In words, \( Z = (Z_k, \ k \geq 0) \) is the restriction of \( X \) on the path \([e, x]\); i.e., it is almost the original walk, except that we remove excursions away from \([e, x]\). Clearly, \( Z \) is a one-dimensional RWRE with (writing \([e, x]\) = \( \{e =: x^{(0)}, x^{(1)}, \ldots, x^{(n)} := x\}\))

\[
P_\omega \left\{ Z_{k+1} = x^{(i+1)} \mid Z_k = x^{(i)} \right\} = \frac{A(x^{(i+1)})}{1 + A(x^{(i+1)})},
P_\omega \left\{ Z_{k+1} = x^{(i-1)} \mid Z_k = x^{(i)} \right\} = \frac{1}{1 + A(x^{(i+1)})},
\]

for all \( 1 \leq i \leq n - 1 \). We observe that

\[
P_\omega \{ T(x) < \tau_0 \} = \omega(e, x^{(1)}) P_\omega \left\{ Z \text{ hits } x^{(n)} \text{ before hitting } e \mid Z_0 = x^{(1)} \right\}
= \omega(e, x^{(1)}) \frac{e^{V(x^{(1)})}}{\sum_{z \in [e, x]} e^{V(z)}},
\]

the second identity following from a general formula (Zeitouni [24], formula (2.1.4)) for the exit problem of one-dimensional RWRE. By ellipticity condition, there exists a constant \( c_{11} > 0 \) such that \( \omega(e, x^{(1)}) e^{V(x^{(1)})} \geq c_{11} \). Plugging this estimate into (2.8) yields

\[
\varrho_n \geq \max_{x \in T_n} \frac{c_{11}}{\sum_{y \in [e, x]} e^{V(y)}},
\]

completing the proof of Proposition 2.4. \( \square \)

The proof of the theorems is organized as follows.

• Section 3: Theorem 2.2, upper bound.

• Section 4: Theorem 2.1 (by means of the upper bound in Theorem 2.2: this is the technical part of the paper).

• Section 3: Theorem 2.2, lower bound (by means of the upper bound in Theorem 2.1).

• Section 3: Theorem 1.1.

### 3 Proof of Theorem 2.2: upper bound

Throughout the section, we assume \( p = \frac{1}{5} \) and \( \psi'(1) = 0 \).

Let

\[
B(x) := \prod_{y \in [e, x]} A(y), \quad x \in T \setminus \{e\}.
\]
We start by recalling a change-of-probability formula from Biggins and Kyprianou [2]. See also Durrett and Liggett [6], and Bingham and Doney [4].

**Fact 3.1 (Biggins and Kyprianou [2])**. For any $n \geq 1$ and any positive measurable function $G$,

$$
\sum_{x \in T_n} E[B(x) G(B(z), z \in [e, x])] = E[G(e^{S_i}, 1 \leq i \leq n)],
$$

where $S_n$ is the sum of $n$ i.i.d. centered random variables whose common distribution is determined by

$$
E[g(S_1)] = b E[A g(\log A)],
$$

for any positive measurable function $g$.

The fact that $S_1$ is centered is a consequence of the assumption $\psi'(1) = 0$. We note that in (3.2), the value of $E[B(x) G(B(z), z \in [e, x])]$ is the same for all $x \in T_n$.

We have now all the ingredients of the proof of the upper bound in Theorem 2.2.

**Proof of Theorem 2.2: upper bound.** By Remark 2.3, only the case $\psi'(1) = 0$ needs to be treated. We assume in the rest of the section ($p = \frac{1}{6}$ and) $\psi'(1) = 0$. The proof borrows some ideas of Bramson [5] concerning branching Brownian motions. Let

$$
E_m := \left\{ x \in T_m : \max_{z \in [e, x]} |V(z)| \leq m^{1/3} \right\}.
$$

We first estimate $E[\#E_m]$:

$$
E[\#E_m] = \sum_{x \in T_m} P \left\{ \max_{z \in [e, x]} |V(z)| \leq m^{1/3} \right\}.
$$

By assumption, for any given $x \in T_m$, $(V(z), z \in [e, x])$ is the set of the first $m$ partial sums of i.i.d. random variables whose common distribution is $A$. By (3.2), this leads to:

$$
E[\#E_m] = E \left( e^{-S_m} 1_{\{\max_{1 \leq i \leq m} |S_i| \leq m^{1/3}\}} \right) \geq P \left\{ \max_{1 \leq i \leq m} |S_i| \leq m^{1/3}, S_m \leq 0 \right\}.
$$

The probability on the right-hand side is a “small deviation” probability, with an unimportant condition upon the terminal value. By a general result of Mogul’skii [17], we have, for all sufficiently large $m$ (say $m \geq m_0$),

$$
E[\#E_m] \geq \exp \left( -c_{12} m^{1/3} \right).
$$

8
We now estimate the second moment of $\#E_m$. For any pair of vertices $x$ and $y$, we write $x < y$ if $x$ is an ancestor of $y$, and $x \leq y$ if $x$ is either $y$ itself or an ancestor of $y$. Then

$$E[(\#E_m)^2] - E[\#E_m]$$

$$= \sum_{u,v \in T_m, u \neq v} P\{u \in E_m, v \in E_m\}$$

$$= \sum_{j=0}^{m-1} \sum_{z \in T_j} \sum_{x \in T_{j+1}: z < x} \sum_{y \in T_{j+1}\{x\}: z < y} \sum_{u \in T_m: x \leq u} \sum_{v \in T_m: y \leq v} P\{u \in E_m, v \in E_m\}.$$ 

In words, $z$ is the youngest common ancestor of $u$ and $v$, while $x$ and $y$ are distinct children of $z$ at generation $j + 1$. If $j = m - 1$, we have $x = u$ and $y = v$, otherwise $x$ is an ancestor of $u$, and $y$ of $v$.

Fix $z \in T_j$, and let $x$ and $y$ be a pair of distinct children of $z$. Let $u \in T_m$ and $v \in T_m$ be such that $x \leq u$ and $y \leq v$. Then

$$P\{u \in E_m, v \in E_m\}$$

$$\leq P\left\{\max_{r \in [e, z]} |V(r)| \leq m^{1/3}\right\} \times \left(P\left\{\max_{r \in [z, x]} |V(r) - V(z)| \leq 2m^{1/3}\right\}\right)^2.$$ 

We have, by $[3,2]$,

$$P\left\{\max_{r \in [e, z]} |V(r)| \leq m^{1/3}\right\} = b^{-j} E\left[e^{-S_j} 1_{\{\max_{1 \leq i \leq j} |S_i| \leq m^{1/3}\}}\right] \leq b^{-j} e^{m^{1/3}},$$

and similarly, $P\{\max_{r \in [z, x]} |V(r) - V(z)| \leq 2m^{1/3}\} \leq b^{-(m-j)} e^{2m^{1/3}}$. Therefore,

$$E[(\#E_m)^2] - E[\#E_m]$$

$$\leq \sum_{j=0}^{m-1} \sum_{z \in T_j} \sum_{x \in T_{j+1}: z < x} \sum_{y \in T_{j+1}\{x\}: z < y} \sum_{u \in T_m: x \leq u} \sum_{v \in T_m: y \leq v} b j^{-2m} e^{5m^{1/3}}$$

$$= \sum_{j=0}^{m-1} \sum_{z \in T_j} b(b - 1) b^{m-j - 1} b^{m-j - 1} b^{j - 2m} e^{5m^{1/3}}$$

$$= \frac{b - 1}{b} m e^{5m^{1/3}}.$$ 

Recall that $E[\#E_m] \geq \exp(-c_{12} m^{1/3})$ for $m \geq m_0$. Therefore, for $m \geq m_0$,

$$\frac{E[(\#E_m)^2]}{E[\#E_m]^2} \leq \frac{b - 1}{b} m e^{(5+2c_{12})m^{1/3}} + e^{c_{12} m^{1/3}} \leq e^{c_{13} m^{1/3}}.$$
By the Cauchy–Schwarz inequality, for \( m \geq m_0 \),
\[
\mathbb{P}\{E_m \neq \emptyset\} = \mathbb{P}\{\#E_m > 0\} \geq \frac{\mathbb{E}[\#E_m]^2}{\mathbb{E}[\#E_m]} \geq e^{-c_{13}m^{1/3}}.
\]

A fortiori, for \( m \geq m_0 \),
\[
\mathbb{P}\{\exists x \in \mathbb{T}_m, V(x) \leq m^{1/3}\} \geq e^{-c_{13}m^{1/3}},
\]
which implies
\[
\mathbb{P}\left\{\min_{x \in \mathbb{T}_m} V(x) > m^{1/3}\right\} \leq 1 - e^{-c_{13}m^{1/3}} \leq \exp\left(-e^{-c_{13}m^{1/3}}\right).
\]

Let \( n > m \). By the ellipticity condition stated in the Introduction, there exists a constant \( c_{14} > 0 \) such that \( \max_{z \in [e, y]} V(z) \leq c_{14} (n - m) \) for any \( y \in \mathbb{T}_{n-m} \). Accordingly, for \( m \geq m_0 \),
\[
\mathbb{P}\left\{\min_{x \in \mathbb{T}_m} V(x) > m^{1/3} + c_{14} (n - m)\right\}
\leq \mathbb{P}\left\{\min_{y \in \mathbb{T}_{n-m}} \min_{x \in \mathbb{T}_m : y < x} \max_{y \in [y, x]} [V(r) - V(y)] > m^{1/3}\right\}
= \left(\mathbb{P}\left\{\min_{s \in \mathbb{T}_m} V(s) > m^{1/3}\right\}\right)^{b^{n-m}}
\leq \exp\left(-b^{n-m}e^{-c_{13}m^{1/3}}\right).
\]

We now choose \( m = m(n) := n - \lfloor c_{15} n^{1/3}\rfloor \), where the constant \( c_{15} \) is sufficiently large such that \( \sum_n \exp(-b^{n-m}e^{-c_{13}m^{1/3}}) < \infty \). Then, by the Borel–Cantelli lemma,
\[
\limsup_{n \to \infty} \frac{1}{n^{1/3}} \min_{x \in \mathbb{T}_n} V(x) \leq 1 + c_{14}c_{15}, \quad \mathbb{P}\text{-a.s.}
\]
yielding the desired upper bound in Theorem 2.2.

4 Proof of Theorem 2.1

Throughout the section, we assume \( p = \frac{1}{6} \) and \( \psi'(1) = 0 \).

Proof of Theorem 2.1: lower bound. The estimate \( \varrho_n \geq e^{-c_4 n^{1/3}} \) (\( \mathbb{P} \)-almost surely for all large \( n \)) follows immediately from the upper bound in Theorem 2.2 (proved in Section 3) by means of Proposition 2.4, with any constant \( c_4 > c_8 \). By Fatou’s lemma, we have \( \liminf_{n \to \infty} e^{c_4 n^{1/3}} \mathbb{E}(\varrho_n) \geq 1 \).
We now introduce the important “additive martingale” $M_n$; in particular, the lower tail behaviour of $M_n$ is studied in Lemma 4.1, by means of another martingale called “multiplicative martingale”. The upper bound in Theorem 2.1 will then be proved based on the asymptotics of $M_n$ and on the just proved lower bound.

Let $B(x) := \prod_{y \in \{e, x\}} A(y)$ (for $x \in T \setminus \{e\}$) as in (3.1), and let

$$M_n := \sum_{x \in T_n} B(x), \quad n \geq 1. \tag{4.1}$$

When $E(A) = \frac{1}{b}$ (which is the case if $p = \frac{1}{b}$ and $\psi'(1) = 0$), the process $(M_n, n \geq 1)$ is a martingale, and is referred to as an associated “additive martingale”.

It is more convenient to study the behaviour of $M_n$ by means of another martingale. It is known (see Liu [12]) that under assumptions $p = \frac{1}{b}$ and $\psi'(1) = 0$, there is a unique non-trivial function $\varphi^* : \mathbb{R}_+ \to (0, 1]$ such that

$$\varphi^*(t) = E\left(\prod_{i=1}^{b} \varphi^*(tA(e_i))\right), \quad t \geq 0. \tag{4.2}$$

(By non-trivial, we mean that $\varphi^*$ is not identically 1.) Let

$$M^*_n := \prod_{x \in T_n} \varphi^*(B(x)), \quad n \geq 1. \tag{4.3}$$

The process $(M^*_n, n \geq 1)$ is also a martingale (Liu [12]). Following Neveu [18], we call $M^*_n$ an associated “multiplicative martingale”.

Since the martingale $M^*_n$ takes values in $(0, 1]$, it converges almost surely (when $n \to \infty$) to, say, $M^*_\infty$, and $E(M^*_\infty) = 1$. It is proved by Liu [12] that $E((M^*_\infty)^t) = \varphi^*(t)$ for any $t \geq 0$.

Recall that for some $0 < \alpha < 1$,

$$\log\left(\frac{1}{\varphi^*(t)}\right) \sim t \log\left(\frac{1}{t}\right), \quad t \to 0, \tag{4.3}$$

$$\log\left(\frac{1}{\varphi^*(s)}\right) \geq c_16 s^\alpha, \quad s \geq 1; \tag{4.4}$$

see Liu ([12], Theorem 2.5) for (4.3), and Liu ([13], Theorem 2.5) for (4.4).

**Lemma 4.1** Assume $p = \frac{1}{b}$ and $\psi'(1) = 0$. For any $\chi > 1/2$, there exists $\delta > 0$ such that for all sufficiently large $n$,

$$\mathbb{P}\{M_n < n^{-\chi}\} \leq \exp\left(-n^{\delta}\right). \tag{4.5}$$
Proof of Lemma 4.1. Let $K > 0$ be such that $\mathbf{P}\{M_\infty^* > e^{-K}\} > 0$. Then $\varphi^*(t) = \mathbf{E}\{(M_\infty^*)^t\} \geq \mathbf{P}\{M_\infty^* > e^{-K}\} e^{-Kt}$ for all $t > 0$. Thus, there exists $c_{17} > 0$ such that for all $t \geq 1$, $\varphi^*(t) \geq e^{-c_{17}t}$.

Let $\varepsilon > 0$. By (4.3) and (4.4), there exists a constant $c_{18}$ such that

$$
\log \left( \frac{1}{M_n^*} \right) = \sum_{x \in T_n} \log \left( \frac{1}{\varphi^*(B(x))} \right) \leq c_{18} \left( J_{1,n} + J_{2,n} + J_{3,n} \right),
$$

where

$$
J_{1,n} := \sum_{x \in T_n} B(x) \left( \log \frac{1}{B(x)} \right) 1_{B(x) < \exp(-n^{(1/2)+\varepsilon})},
$$

$$
J_{2,n} := \sum_{x \in T_n} B(x) \left( \log \frac{e}{B(x)} \right) 1_{\exp(-n^{(1/2)+\varepsilon}) \leq B(x) \leq 1},
$$

$$
J_{3,n} := \sum_{x \in T_n} B(x) 1_{B(x) > 1}.
$$

Clearly, $J_{3,n} \leq \sum_{x \in T_n} B(x) = M_n$, whereas $J_{2,n} \leq (n^{(1/2)+\varepsilon} + 1)M_n$. Hence, $J_{2,n} + J_{3,n} \leq (n^{(1/2)+\varepsilon} + 2)M_n \leq 2n^{(1/2)+\varepsilon}M_n$ (for $n \geq 4$). Accordingly, for $n \geq 4$,

$$
(4.6) \quad n^{(1/2)+\varepsilon}M_n \geq \frac{1}{2c_{18}} \log \left( \frac{1}{M_n^*} \right) - \frac{1}{2} J_{1,n}.
$$

We now estimate the tail probability of $M_n^*$. Let $\lambda \geq 1$ and $z > 0$. By Chebyshev’s inequality,

$$
\mathbf{P} \left\{ \log \left( \frac{1}{M_n^*} \right) < z \right\} \leq e^{\lambda z} \mathbf{E} \{ (M_n^*)^\lambda \}.
$$

Since $M_n^*$ is a bounded martingale, $\mathbf{E} \{ (M_n^*)^\lambda \} \leq \mathbf{E} \{ (M_\infty^*)^\lambda \} = \varphi^*(\lambda)$. Therefore,

$$
\mathbf{P} \left\{ \log \left( \frac{1}{M_n^*} \right) < z \right\} \leq e^{\lambda z} \varphi^*(\lambda).
$$

Choosing $z := 4c_{18}n^{-\varepsilon}$ and $\lambda := n^\varepsilon$, it follows from (4.4) that

$$
\mathbf{P} \left\{ \log \left( \frac{1}{M_n^*} \right) < 4c_{18}n^{-\varepsilon} \right\} \leq \exp \left( 4c_{18} - c_{16}n^{\varepsilon\alpha} \right).
$$

Plugging this into (4.6) yields that for $n \geq 4$,

$$
(4.7) \quad \mathbf{P} \left\{ n^{(1/2)+\varepsilon}M_n + \frac{1}{2} J_{1,n} < 2n^{-\varepsilon} \right\} \leq \exp \left( 4c_{18} - c_{16}n^{\varepsilon\alpha} \right).
$$
We note that $J_{1,n} \geq 0$. By (3.2),
\[ E(J_{1,n}) = E\left\{ (-S_n) 1_{\{S_n < -n^{(1/2)+\varepsilon}\}} \right\}. \]
Recall that $S_n$ is the sum of $n$ i.i.d. bounded centered random variables. It follows that for all sufficiently large $n$,
\[ E(J_{1,n}) \leq \exp\left( -c_{19} n^{2\varepsilon} \right). \]
By (4.7) and Chebyshev’s inequality,
\[
\begin{align*}
\P\{ n^{(1/2)+\varepsilon} M_n < n^{-\varepsilon} \} & \leq \P\left\{ n^{(1/2)+\varepsilon} M_n + \frac{1}{2} J_{1,n} < 2n^{-\varepsilon} \right\} + \P\{ J_{1,n} \geq 2n^{-\varepsilon} \} \\
& \leq \exp\left( 4c_{18} - c_{16} n^{\varepsilon} \right) + \frac{n^\varepsilon}{2} \exp\left( -c_{19} n^{2\varepsilon} \right),
\end{align*}
\]
from which (4.3) follows. □

We have now all the ingredients for the proof of the upper bound in Theorem 2.1.

Proof of Theorem 2.1: upper bound. We only need to prove the upper bound in (2.2), namely, there exists $c_5$ such that for all large $n$,
\[ E(\bar{\varrho}_n) \leq e^{-c_5 n^{1/3}}. \]
(4.8)

If (4.8) holds, then the upper bound in (2.1) follows by an application of Chebyshev’s inequality and the Borel–Cantelli lemma.

It remains to prove (4.8). For any $x \in T \setminus \{e\}$, we define
\[ \beta_n(x) := P_\omega \left\{ \text{starting from } x, \text{ the RWRE hits } T_n \text{ before hitting } \bar{x} \right\}, \]
where, as before, $\bar{x}$ is the parent of $x$. In the notation of (2.7),
\[ \beta_n(x) = P_\omega \{ T_n < T(\bar{x}) \mid X_0 = x \}, \]
where $T_n := \min_{x \in T_n} T(x)$. Clearly, $\beta_n(x) = 1$ if $x \in T_n$.

Recall that for any $x \in T$, $\{x_i\}_{1 \leq i \leq b}$ is the set of the children of $x$. By the Markov property, if $1 \leq |x| \leq n - 1$, then
\[ \beta_n(x) = \sum_{i=1}^{b} \omega(x, x_i) P_\omega \{ T_n < T(\bar{x}) \mid X_0 = x_i \}. \]
Consider the event \( \{ T_n < T(\bar{x}) \} \) when the walk starts from \( x_i \). There are two possible situations: (i) either \( T_n < T(x) \) (which happens with probability \( \beta_n(x_i) \), by definition); (ii) or \( T_n > T(x) \) and after hitting \( x \) for the first time, the walk hits \( T_n \) before hitting \( \bar{x} \). By the strong Markov property, \( P_\omega \{ T_n < T(\bar{x}) \mid X_0 = x_i \} = \beta_n(x_i) + [1 - \beta_n(x_i)] \beta_n(x) \). Therefore,

\[
\beta_n(x) = \sum_{i=1}^{b} \omega(x, x_i) \beta_n(x_i) + \beta_n(x) \sum_{i=1}^{b} \omega(x, x_i) [1 - \beta_n(x_i)] \\
= \sum_{i=1}^{b} \omega(x, x_i) \beta_n(x_i) + \beta_n(x) [1 - \omega(x, \bar{x})] - \beta_n(x) \sum_{i=1}^{b} \omega(x, x_i) \beta_n(x_i),
\]

from which it follows that

\[
\beta_n(x) = \frac{\sum_{i=1}^{b} A(x_i) \beta_n(x_i)}{1 + \sum_{i=1}^{b} A(x_i) \beta_n(x_i)}; \quad 1 \leq |x| \leq n - 1.
\]

Together with condition \( \beta_n(x) = 1 \) (for \( x \in \mathbb{T}_n \)), these equations determine the value of \( \beta_n(x) \) for all \( x \in \mathbb{T} \) such that \( 1 \leq |x| \leq n \).

We introduce the random variable

\[
\beta_n(e) := \frac{\sum_{i=1}^{b} A(e_i) \beta_n(e_i)}{1 + \sum_{i=1}^{b} A(e_i) \beta_n(e_i)}.
\]

The value of \( \beta_n(e) \) for given \( \omega \) is of no importance, but the distribution of \( \beta_n(e) \), which is identical to that of \( \beta_{n+1}(e_1) \), plays a certain role in several places of the proof. For example, for \( 1 \leq |x| < n \), the random variables \( \beta_n(x) \) and \( \beta_{n-|x|}(e) \) have the same distribution; in particular, \( \mathbb{E}[\beta_n(x)] = \mathbb{E}[\beta_{n-|x|}(e)] \). In the rest of the section, we make frequent use of this property without further mention. We also make the trivial observation that for \( 1 \leq |x| < n \), \( \beta_n(x) \) depends only on those \( A(y) \) such that \( |x| + 1 \leq |y| \leq n \) and that \( x \) is an ancestor of \( y \).

Recall that \( q_n = P_\omega \{ \tau_n < \tau_0 \} \). Therefore,

\[
q_n = \sum_{i=1}^{b} \omega(e, e_i) \beta_n(e_i).
\]

In particular,

\[
\mathbb{E}(q_n) = \mathbb{E}[\beta_n(e_i)] = \mathbb{E}[\beta_{n-1}(e)], \quad \forall 1 \leq i \leq b.
\]

Let \( a_j := \mathbb{E}(q_{n,j+1}) = \mathbb{E}[\beta_j(e)], \ \ j = 0, 1, 2, \ldots, \lfloor n^{4/3} \rfloor \). Clearly, \( a_0 = 1 \), and \( j \mapsto a_j \) is non-increasing for \( 0 \leq j \leq \lfloor n^{4/3} \rfloor \). We look for an upper bound for \( a_{\lfloor n^{4/3} \rfloor} \).
Let \( m > \Delta \geq 1 \) be integers. Let \( 1 \leq i \leq b \), and let \((e_{ij}, 1 \leq j \leq b)\) be the set of children of \( e_i \). By (4.9), we have
\[
\beta_m(e_i) \leq \sum_{j=1}^{b} A(e_{ij}) \beta_m(e_{ij}).
\]
Iterating the same argument, we arrive at:
\[
\beta_m(e_i) \leq \sum_{y \in T_{\Delta}: y < e_i} \left( \prod_{e_i < z, z \leq y} A(z) \right) \beta_m(y) = \sum_{y \in T_{\Delta}: y < e_i} \frac{B(y)}{A(e_i)} \beta_m(y).
\]
By (4.10), this yields
\[
\beta_m(e) \leq \frac{\sum_{i=1}^{b} \sum_{y \in T_{\Delta}: y < e_i} B(y) \beta_m(y)}{1 + \sum_{y \in T_{\Delta}} B(y) \beta_m(y)} = \frac{\sum_{y \in T_{\Delta}} B(y) \beta_m(y)}{1 + \sum_{y \in T_{\Delta}} B(y) \beta_m(y)}.
\]
Fix \( n \) and \( 0 \leq j \leq \lfloor n^{1/3} \rfloor - 1 \). Let
\[
\Delta = \Delta(j) := (j + 1)^3 - j^3 = 3j^2 + 3j + 1.
\]
Then
\[
a_{j+1} = \mathbb{E}[\beta_{(j+1)^3}(e)] \leq \mathbb{E} \left( \frac{\sum_{y \in T_{\Delta}} B(y) \beta_{(j+1)^3}(y)}{1 + \sum_{y \in T_{\Delta}} B(y) \beta_{(j+1)^3}(y)} \right).
\]
We note that \((\beta_{(j+1)^3}(y), y \in T_{\Delta})\) is a collection of i.i.d. random variables distributed as \( \beta_{3j}(e) \), and is independent of \((B(y), y \in T_{\Delta})\).

Let \((\xi(x), x \in T)\) be i.i.d. random variables distributed as \( \beta_{3j}(e) \), independent of all other random variables and processes. Let
\[
N_m := \sum_{x \in T_m} B(x) \xi(x), \quad m \geq 1.
\]
The last inequality can be written as
\[
(4.13) \quad a_{j+1} \leq \mathbb{E} \left( \frac{N_{\Delta}}{1 + N_{\Delta}} \right).
\]
By definition,
\[
(4.14) \quad \mathbb{E} \left( \frac{N_{\Delta}}{1 + N_{\Delta}} \right) = \sum_{x \in T_{\Delta}} \mathbb{E} \left( \frac{B(x) \xi(x)}{1 + N_{\Delta}} \right) = \sum_{x \in T_{\Delta}} \mathbb{E} \left\{ B(x) \xi(x) e^{-YN_{\Delta}} \right\},
\]
where \( Y \) is an exponential random variable of parameter 1, independent of everything else.
Let us fix \( x \in T_\Delta \), and estimate \( \mathbb{E}\{B(x)\xi(x)e^{-YN_{\Delta}}\} \). Since \( N_m = \sum_{x \in T_m} B(x)\xi(x) \) (for any \( m \geq 1 \)), we have
\[
N_{\Delta} \geq B(\bar{x})A(y)\xi(y),
\]
for any \( y \in T_{\Delta}\setminus\{x\} \) such that \( \bar{y} = \bar{x} \). Note that by ellipticity condition, \( A(y) \geq c > 0 \) for some constant \( c \). Accordingly,
\[
\mathbb{E} \{B(x)\xi(x)e^{-YN_{\Delta}}\} \leq \mathbb{E} \{B(x)\xi(x)e^{-cYB(\bar{x})\xi(y)}\} = \mathbb{E} \{\xi(x)\} \mathbb{E} \{B(x)e^{-cYB(\bar{x})\xi(y)}\}.
\]
Recall that \( \mathbb{E}\{\xi(x)\} = \mathbb{E}\{\beta_{j,3}(e)\} = a_j \) and that \( \xi(y) \) is distributed as \( \beta_{j,3}(e) \), independent of \( (B(x),Y,B(\bar{x})) \). At this stage, it is convenient to recall the following inequality (see [4] for an elementary proof): if \( \mathbb{E}(A) = \frac{1}{b} \) (which is guaranteed by the assumption \( p = \frac{1}{b} \) and \( \psi'(1) = 0 \)), then
\[
\mathbb{E} \left\{ \exp \left( -t \frac{\beta_{k}(e)}{\mathbb{E}[\beta_{k}(e)]} \right) \right\} \leq \mathbb{E} \left\{ e^{-tM_k} \right\}, \quad \forall k \geq 1, \ \forall t \geq 0,
\]
where \( M_k \) is defined in ([4.3]). As a consequence,
\[
\mathbb{E} \{B(x)\xi(x)e^{-YN_{\Delta}}\} \leq a_j \mathbb{E} \left\{ B(x)e^{-cYB(\bar{x})a_j\widetilde{M}_{j,3}} \right\},
\]
where \( \widetilde{M}_{j,3} \) is distributed as \( M_{j,3} \), and is independent of everything else. Since \( A(x) = \frac{B(x)}{B(\bar{x})} \) is independent of \( B(\bar{x}) \) (and \( Y \) and \( \widetilde{M}_{j,3} \)), with \( \mathbb{E}\{A(x)\} = \frac{1}{b} \), this yields
\[
\mathbb{E} \{B(x)\xi(x)e^{-YN_{\Delta}}\} \leq \frac{a_j}{b} \mathbb{E} \left\{ B(\bar{x})e^{-ca_jYB(\bar{x})\widetilde{M}_{j,3}} \right\}.
\]
Plugging this into (4.14), we see that
\[
\mathbb{E} \left( \frac{N_{\Delta}}{1 + N_{\Delta}} \right) \leq a_j \sum_{u \in T_{\Delta-1}} \mathbb{E} \left\{ B(u)e^{-ca_jYB(u)\widetilde{M}_{j,3}} \right\} = a_j \mathbb{E} \left\{ \exp \left( -ca_j Y e^{S_{\Delta-1}\widetilde{M}_{j,3}} \right) \right\},
\]
the last identity being a consequence of (3.2), the random variables \( Y, S_{\Delta-1} \) and \( \widetilde{M}_{j,3} \) being independent. By (4.13), \( a_{j+1} \leq \mathbb{E}(\frac{N_{\Delta}}{1 + N_{\Delta}}) \). Thus
\[
a_{j+1} \leq a_j \mathbb{E} \left\{ \exp \left( -ca_j Y e^{S_{\Delta-1}\widetilde{M}_{j,3}} \right) \right\}.
\]
As a consequence,
\[ a_{\lfloor n^{1/3} \rfloor} \leq \prod_{j=0}^{\lfloor n^{1/3} \rfloor - 1} \mathbb{E} \left\{ \exp \left( -c a_j Y e^{S_{\Delta - 1}} \tilde{M}_j^3 \right) \right\}. \]

We claim that for any collection of non-negative random variables \((\eta_j, 0 \leq j \leq n)\) and \(\lambda \geq 0,
\[ \prod_{j=0}^{n} \mathbb{E} \left( e^{-\eta_j} \right) \leq e^{-\lambda} + \prod_{j=0}^{n} \mathbb{P} \{ \eta_j < \lambda \}. \]

Indeed, without loss of generality, we can assume that \(\eta_j\) are independent; then
\[ \prod_{j=0}^{n} \mathbb{E} \left( e^{-\eta_j} \right) \leq \mathbb{E} \left( e^{-\max_{0 \leq j \leq n} \eta_j} \right) \leq e^{-\lambda} + \prod_{j=0}^{n} \mathbb{P} \{ \eta_j < \lambda \}, \]

as claimed.

We have thus proved that
\[ a_{\lfloor n^{1/3} \rfloor} \leq e^{-n} + \prod_{j=0}^{\lfloor n^{1/3} \rfloor - 1} \mathbb{P} \left\{ c a_j Y e^{S_{\Delta - 1}} \tilde{M}_j^3 < n \right\}. \]

Recall that \(a_j = \mathbb{E}(\varphi_{j+1})\). By the already proved lower bound in Theorem 2.1, we have
\[ a_j \geq \exp(-c_6 j) \] for \(j \geq j_0\). Hence, for \(j_0 \leq j \leq \lfloor n^{1/3} \rfloor - 1,\)
\[ \mathbb{P} \left\{ c a_j Y e^{S_{\Delta - 1}} \tilde{M}_j^3 \geq n \right\} \geq \mathbb{P} \{ Y \geq 1 \} \mathbb{P} \left\{ \tilde{M}_j^3 \geq \frac{1}{j^3} \right\} \mathbb{P} \left\{ S_{\Delta - 1} \geq c_6 j + \log \left( \frac{j^3 n}{c} \right) \right\}. \]

Of course, \(\mathbb{P} \{ Y \geq 1 \} = e^{-1};\) and by (4.5), \(\mathbb{P} \{ \tilde{M}_j^3 \geq \frac{1}{j^3} \} = \mathbb{P} \{ M_j^3 \geq \frac{1}{j^3} \} \geq \frac{1}{2} \) for all large \(j\).
On the other hand, since \(\Delta - 1 \geq 3j^2,\) we have \(\mathbb{P} \{ S_{\Delta - 1} \geq c_6 j + \log \left( \frac{j^3 n}{c} \right) \} \geq c_20 > 0 \) for large \(n\) and all \(j \geq \log n.\) We have thus proved that, for large \(n\) and some constant \(c_21 \in (0, 1),\)
\[ a_{\lfloor n^{1/3} \rfloor} \leq e^{-n} + \prod_{j=\lfloor \log n \rfloor}^{\lfloor n^{1/3} \rfloor - 1} (1 - c_21) \leq \exp \left( -c_22 n^{1/3} \right). \]
Since \(a_{\lfloor n^{1/3} \rfloor} = \mathbb{E}(\varphi_{\lfloor n^{1/3} \rfloor + 1}) \geq \mathbb{E}(\varphi_{n+1}),\) this yields (4.8), and thus the upper bound in Theorem 2.1.

5 Proof of Theorem 2.2: lower bound

Without loss of generality (see Remark 2.3), we can assume \(\psi'(1) = 0.\) In this case, the lower bound in Theorem 2.2 follows from the upper bound in Theorem 2.1 (proved in the previous section) by means of Proposition 2.4, with \(c_7 := c_3.\) \(\square\)
6 Proof of Theorem 1.1

For the sake of clarity, Theorem 1.1 is proved in two distinct parts.

6.1 Upper bound

We first assume $\psi'(1) = 0$. By Theorem 2.1, $P_\omega\{\tau_n < \tau_0\} = \varrho_n \leq \exp(-c_3 n^{1/3})$, $P$-almost surely for all large $n$. Hence, by writing $L(\tau_n) := \#\{1 \leq i \leq \tau_n : X_i = e\}$, we obtain: $P$-almost surely for all large $n$ and any $j \geq 1$,

$$P_\omega\{L(\tau_n) \geq j\} = [P_\omega\{\tau_n > \tau_0\}]^j \geq [1 - e^{-c_3 n^{1/3}}]^j,$$

which, by the Borel–Cantelli lemma, implies that, for any constant $c_{23} < c_3$ and $P$-almost surely all sufficiently large $n$,

$$L(\tau_n) \geq e^{c_{23} n^{1/3}}.$$

Since $\{L(\tau_n) \geq j\} \subset \{X_{2j} < n\}$, we obtain the desired upper bound in Theorem 1.1 (case $\psi'(1) = 0$), with $c_2 := 1/(c_3)^3$.

To treat the case $\psi'(1) > 0$, we first consider an RWRE $(Y_k, k \geq 0)$ on the half-line $\mathbb{Z}_+$ with a reflecting barrier at the origin. We write $T_Y(y) := \inf\{k \geq 0 : Y_k = y\}$ for $y \in \mathbb{Z}_+ \setminus \{0\}$. Then

$$P_\omega\{T_Y(y) \leq m\} = \sum_{i=1}^m P_\omega\{T_Y(y) = i\} \leq \sum_{i=1}^m P_\omega\{Y_i = y\} = \sum_{i=1}^m \omega^i(0, y),$$

where, by an abuse of notation, we use $\omega(\cdot, \cdot)$ to denote also the transition matrix of $(Y_k)$. Since $(Y_k)$ is reversible, we have $\omega^i(0, y) = \frac{\pi(y)}{\pi(0)} \omega^i(y, 0)$, where $\pi$ is an invariant measure. Accordingly,

$$P_\omega\{T_Y(y) \leq m\} \leq \sum_{i=1}^m \frac{\pi(y)}{\pi(0)} \omega^i(y, 0) \leq m \frac{\pi(y)}{\pi(0)}.$$

As a consequence, for any $n \geq 1$,

$$P_\omega\{T_Y(n) \leq m\} \leq \min_{1 \leq y \leq n} P_\omega\{T_Y(y) \leq m\} \leq m \min_{1 \leq y \leq n} \frac{\pi(y)}{\pi(0)}.$$

It is easy to compute $\pi$: we can take $\pi(0) = 1$ and

$$\pi(y) := \sum_{z=1}^y \log \frac{\omega(z, z-1)}{\omega(z, z+1)}, \quad y \in \mathbb{Z}_+ \setminus \{0\}.$$
Therefore, for \( n \geq 1 \),

\[
(6.1) \quad P_\omega \{ T_Y(n) \leq m \} \leq m \min_{y \in [e, x]} A(y) = m e^{-V(x)},
\]

where \( V(x) \) is defined in (2.3).

We now come back to the study of \( X \), the RWRE on \( \mathbb{T} \). Fix \( x \in \mathbb{T}_n \). Let \( Z \) be the restriction of \( X \) on the path \([e, x]\) as in (2.9). Let \( T_Z(x) := \inf \{ k \geq 0 : Z_k = x \} \). By (6.1), we have

\[
P_\omega \{ T_Z(x) \leq m \} \leq m e^{-V(x)}.
\]

It follows from the trivial inequality \( T_Z(x) \geq T_Z(x) \) that

\[
P_\omega \{ \tau_n \leq m \} \leq \sum_{x \in \mathbb{T}_n} P_\omega \{ T_Z(x) \leq m \} \leq m \sum_{x \in \mathbb{T}_n} e^{-V(x)}.
\]

Since \( \psi'(1) > 0 \), we can consider \( 0 < \theta < 1 \) as in (2.5). Then

\[
\sum_{x \in \mathbb{T}_n} e^{-\theta V(x)} \leq \exp \left( - (1 - \theta) \min_{x \in \mathbb{T}_n} V(x) \right) \sum_{x \in \mathbb{T}_n} e^{-V(x)}.
\]

Since \( E(A^\theta) = 1 \), it is easily seen that \( \sum_{x \in \mathbb{T}_n} e^{-\theta V(x)} \) is a positive martingale. In particular, \( \sup_{n \geq 1} \sum_{x \in \mathbb{T}_n} e^{-\theta V(x)} < \infty, \) \( \mathbb{P} \)-almost surely. On the other hand, according to Theorem 2.2, we have \( \min_{x \in \mathbb{T}_n} V(x) \geq c_7 n^{1/3}, \) \( \mathbb{P} \)-almost surely for all large \( n \). Therefore, for any constant \( c_{24} < (1 - \theta)c_7 \), we have

\[
\sum_n \mathbb{P} \left\{ \tau_n \leq e^{c_{24} n^{1/3}} \right\} < \infty, \quad \mathbb{P} \text{-a.s.},
\]

from which the upper bound in Theorem 1.1 (case \( \psi'(1) > 0 \)) follows readily, with \( c_2 := 1/[(1 - \theta)c_7]^{3} \).

### 6.2 Lower bound

By means of the Markov property, one can easily get a recurrence relation for \( E_\omega(\tau_n) \), from which it follows that for \( n \geq 1 \),

\[
(6.2) \quad E_\omega(\tau_n) = \frac{\gamma_n(e)}{\theta_n},
\]

where \( \theta_n \) and \( \gamma_n(e) \) are defined by: \( \beta_n(x) = 1 \) and \( \gamma_n(x) = 0 \) (for \( x \in \mathbb{T}_n \)), and

\[
\beta_n(x) = \frac{\sum_{i=1}^b A(x_i) \beta_n(x_i)}{1 + \sum_{i=1}^b A(x_i) \beta_n(x_i)},
\]

\[
\gamma_n(x) = \frac{[1/\omega(x, \overrightarrow{x})] + \sum_{i=1}^b A(x_i) \gamma_n(x_i)}{1 + \sum_{i=1}^b A(x_i) \beta_n(x_i)}, \quad 1 \leq |x| \leq n,
\]

\[
\gamma_n(e) = \frac{\sum_{i=1}^b A(e_i) \gamma_n(x_i)}{1 + \sum_{i=1}^b A(e_i) \beta_n(x_i)},
\]

\[
\theta_n = \frac{\sum_{i=1}^b A(e_i) \theta_n(x_i)}{1 + \sum_{i=1}^b A(e_i) \beta_n(x_i)},
\]

\[
\theta_n(e) = \frac{\sum_{i=1}^b A(e_i) \theta_n(x_i)}{1 + \sum_{i=1}^b A(e_i) \beta_n(x_i)},
\]

\[
\theta_n(x) = \frac{[1/\omega(x, \overrightarrow{x})] + \sum_{i=1}^b A(x_i) \theta_n(x_i)}{1 + \sum_{i=1}^b A(x_i) \beta_n(x_i)}, \quad 1 \leq |x| \leq n.
\]
and \( g_n := \sum_{i=1}^{b} \omega(e, e_i) \beta_n(e_i), \gamma_n(e) := \sum_{i=1}^{b} \omega(e, e_i) \gamma_n(e_i) \). See Rozikov [20] for more details. As a matter of fact, \( \beta_n(x) \) (for \( 1 \leq |x| \leq n \)) is the same as the one introduced in (4.4), and \( g_n \) can also be expressed as \( P_\omega \{ \tau_n < \tau_0 \} \).

We claim that
\[
\sup_{n \geq 1} \frac{\gamma_n(e)}{n} < \infty, \quad \mathbb{P}\text{-a.s.}
\]

By admitting (6.3) for the moment, we are able to prove the lower bound in Theorem 1.1. Indeed, in view of (the lower bound in) Theorem 2.1 and (6.2), we have \( E_\omega(\tau_n) \leq c_{25}(\omega) n \exp(c_4 n^{1/3}) \), \( \mathbb{P}\)-almost surely for all large \( n \). It follows from Chebyshev’s inequality and the Borel–Cantelli lemma that \( \mathbb{P}\)-almost surely for all sufficiently large \( n \),
\[
\tau_n \leq c_{25}(\omega) n^3 \exp(c_4 n^{1/3}),
\]
which yields
\[
\liminf_{n \to \infty} \frac{X_n^*}{(\log n)^3} \geq \frac{1}{(c_4)^3}, \quad \mathbb{P}\text{-a.s.}
\]
This is the desired lower bound in Theorem 1.1.

It remains to prove (6.3). By the ellipticity condition, \( \omega(x, \cdot) \leq c_{26} \), so that
\[
\gamma_n(x) \leq c_{26} + \sum_{i=1}^{b} A(x_i) \gamma_n(x_i).
\]
Iterating the inequality, we obtain:
\[
\gamma_n(e) \leq c_{26} \left( 1 + \sum_{j=1}^{n-1} \sum_{x \in T_j, \ y \in [e_i, x]} A(y) \right) = c_{26} \left( 1 + \sum_{j=1}^{n-1} M_j \right), \quad n \geq 2.
\]
where \( M_j \) is already introduced in (4.1).

There exists \( 0 < \theta \leq 1 \) such that \( \mathbb{E}(A^\theta) = \frac{1}{\theta} \): indeed, if \( p = \frac{1}{\theta} \) and \( \psi'(1) = 0 \), then we simply take \( \theta = 1 \), whereas if \( p = \frac{1}{\theta} \) and \( \psi'(1) > 0 \), then we take \( 0 < \theta < 1 \) as in (2.5). We have
\[
M_j^\theta \leq \sum_{x \in T_j, \ y \in [e_i, x]} A(y)^\theta.
\]
Since \( j \mapsto \sum_{x \in T_j, \ y \in [e_i, x]} A(y)^\theta \) is a positive martingale, we have \( \sup_{j \geq 1} M_j < \infty \), \( \mathbb{P}\)-almost surely. This yields (6.3), and thus completes the proof of the lower bound in Theorem 1.1. \( \square \)
