Abstract

We study large partial sums, localized with respect to the sums of variances, of a sequence of centered random variables. An application is given to the distribution of prime factors of typical integers.

Key words: sums of random variables, prime divisors
1991 MSC: 60G50, 11N25

Dedicated to the memory of Walter Philipp

1 Introduction

Consider random variables $X_1, X_2, \ldots$ with $E X_j = 0$ and $E X_j^2 = \sigma_j^2$. Let

$$S_n = X_1 + \cdots + X_n, \quad s_n^2 = \sigma_1^2 + \cdots + \sigma_n^2,$$

and assume that (a) $s_n \to \infty$ as $n \to \infty$.

Preprint submitted to Elsevier 13 March 2007
Given a positive function \( f_N \geq 1 + 1/N \), we are interested in the behavior of

\[
I = \lim \inf_{N \to \infty} \max_{N < s_n \leq N f_N} |S_n|/s_n.
\]

If we replace \( \lim \inf \) by \( \lim \sup \), it immediately follows from the law of the iterated logarithm that \( I = \infty \) almost surely when \( f_N \) is bounded. Our results answer a question originally raised, in oral form, by A. Sárközy and for which a partial answer had previously been given by the second author, see Chap. 3 of Oon (2005).

2 Independent random variables

Assume that the \( X_j \) are independent. Then \( \mathbb{E} S_n^2 = s_n^2 \). In addition to condition (a), we will work with two other mild assumptions, (b) \( s_{j+1}/s_j \ll 1 \) when \( s_j > 0 \) and (c) for every \( \lambda > 0 \), there is a constant \( c_\lambda > 0 \) such that if \( n \) is large enough and \( s_m^2 > 2s_n^2 \), then

\[
\mathbb{P} (|S_m - S_n| \geq \lambda s_m) \geq c_\lambda.
\]

Condition (b) says that no term in \( S_n \) dominates the others. Condition (c) follows if the Central Limit Theorem (CLT) holds for the sequence of \( S_n \), since CLT for \( S_n \) implies CLT for \( S_m - S_n \) as \( (m - n) \to \infty \). For example, (c) holds for i.i.d. random variables, under the Lindeberg condition

\[
\forall \varepsilon > 0, \lim_{n \to \infty} \sum_{1 \leq j \leq n} \mathbb{E} \left( \frac{X_j^2}{s_n^2} : |X_j| > \varepsilon s_n \right) = 0
\]

and the stronger Lyapunov condition

\[
\exists \delta > 0 : \sum_{1 \leq j \leq n} \mathbb{E}|X_j|^{2+\delta} = o(s_n^{2+\delta}).
\]

Condition (c) is weaker, however, than CLT.

**Theorem 1** (i) Suppose (a), (b), and \( f_N = (\log N)^M \) for some constant \( M > 0 \). Then \( I < \infty \) almost surely.

(ii) Suppose (a), (b), (c) and \( f_N = (\log N)^{\xi(N)} \) with \( \xi(N) \) tending monotonically to \( \infty \). Then \( I = \infty \) almost surely.

**Remark.** In the first statement of the theorem we show in fact that almost surely

\[
I \leq 15\sqrt{M + 1} (\max_{s_j > 0} s_{j+1}/s_j)^2.
\]

**Lemma 2 (Kolmogorov’s inequality, 1929)** We have

\[
\mathbb{P}(\max_{1 \leq j \leq k} |S_j| \geq \lambda s_k) \leq 1/\lambda^2 \quad (k \geq 1).
\]
Proof of Theorem 1. By (a) and (b), there is a constant $D$ so that $s_{j+1}/s_j \leq D$ for all large $j$. Define

$$h(n) := \max \{ k : s_k^2 \leq n \} \quad (n \in \mathbb{N}^+),$$

so that the conditions $N < s_n^2 \leq N f_N$ and $h(N) < n \leq h(N f_N)$ are equivalent.

We first consider the case when $f_N := (\log N)^M$. Let

$$N_j := j^{(M+3)j}, \quad t(j) := [(M + 1)(\log j)/\log 2], \quad H_j := 2^{t(j)},$$

and

$$U_j := h(N_j), \quad U_{j,t} := h(2^t N_j) \quad (0 \leq t \leq t(j)), \quad V_j := h(H_j N_j) = U_{j,t(j)}.$$

It is possible that $U_{j,t+1} = U_{j,t}$ for some $t$. Note that for large $j$, $H_j N_j \geq N_j f_{N_j}$.

Let $k$ be a constant depending only on $M$ and $D$. For $j \geq 1$ define the events

$$A_j := \{|S_{V_j}| \leq s_{U_{j+1}}\},$$

$$B_{j,t} := \bigcap_{0 \leq t \leq t(j) - 1} \bigg\{ \max_{U_{j+1,t} \leq n < U_{j+1,t+1}} |S_{U_{j+1,t+1}} - S_n| \leq k s_{U_{j+1,t}} \bigg\},$$

$$C_j := \{|S_{U_{j+1}} - S_{V_j}| \leq 2 s_{U_{j+1}}\}.$$

By (b) and the definition of $h(N)$, we have

$$D^{-1} \sqrt{2^t N_j} \leq s_{U_{j,t}} \leq \sqrt{2^t N_j} \quad (1)$$

for all $j, t$. It follows from Lemma 2 that

$$\mathbb{P}(\overline{A_j}) \leq D^2 H_j N_j / N_{j+1} \leq \frac{D^2}{j^2}.$$

Thus, $\Sigma_{j \geq 1} \mathbb{P}(\overline{A_j}) < \infty$ and hence almost surely there is a $j_0$ so that $A_j$ occurs for $j \geq j_0$. Applying Lemma 2 again yields

$$\mathbb{P}(\overline{B_{j,t}}) \leq \frac{s_{U_{j+1,t+1}}^2 - s_{U_{j+1,t}}^2}{k^2 s_{U_{j+1,t}}^2} \leq \frac{D^2 2^{t+1} N_{j+1}}{k^2 2^t N_{j+1}} = \frac{2 D}{k^2}.$$

If $k = 3 D \sqrt{M + 1}$, then

$$\mathbb{P}(B_j) \geq \left(1 - \frac{2 D^2}{k^2}\right)^{t(j)} \geq \frac{1}{j^{1/2}}$$

for large $j$. Also by Lemma 2, $\mathbb{P}(C_j) \geq \frac{3}{4}$, and since $B_j$ and $C_j$ are independent,

$$\Sigma_{j \geq 1} \mathbb{P}(B_j C_j) = \infty.$$
Since the events $B_j C_j$ are independent, the Borel–Cantelli lemma implies that almost surely the events $B_j C_j$ occur infinitely often. Thus, the event $A_j B_j C_j$ occurs for an infinite sequence of integers $j$. Take such an index $j$, let $n \in [U_{j+1}, V_{j+1}]$ and $U_{j+1, g-1} \leq n < U_{j+1, g}$, where $1 \leq g \leq t(j + 1)$. We have by several applications of (1)

$$|S_n| \leq |S_{V_j}| + |S_{U_{j+1}} - S_{V_j}| + \sum_{0 \leq t \leq g-2} |S_{U_{j+1,t}} - S_{U_{j+1,t+1}}| + |S_n - S_{U_{j+1, g-1}}|$$

\[ \leq 3s_{U_{j+1}} + k \sum_{0 \leq t \leq g-1} s_{U_{j+1,t}} \]

\[ \leq \left\{ 3 + k(1 + 2^{1/2} + \cdots + 2^{(g-1)/2}) \right\} \sqrt{N_{j+1}} \]

\[ \leq 5k \sqrt{2^{g-1}N_{j+1}} \]

\[ \leq 5kD_s n = 15D^2(M + 1)^{1/2}s_n. \]

This completes the proof of part (i) of the theorem, since

$$V_{j+1} \geq h(\frac{1}{2}j^{M+1}N_j) \geq h(N_j \log^M N_j)$$

for large $j$.

Now suppose $f_N = (\log N)^{\xi(N)}$ with $\xi(N)$ tending monotonically to $\infty$.

Let $\lambda > 0$ be arbitrary and define $K := 2D^2$. Let $N_1^*$ be so large that $f_{N_1^*} \geq K$. For $j \geq 1$ let $N_{j+1}^* = N_j^* K^{u(j)}$, where $u(j) := \left[ \log f_{N_j^*} / \log K \right]$. Put

$$U_j^* := h(N_j^*), \quad U_{j,t}^* := h(K^t N_j^*) \quad (0 \leq t \leq u(j)).$$

Let $J := [U_j^*, U_{j+1}^*]$ and

$$Y_j := \max_{n \in J_j} |S_n|/s_n.$$

We have

$$u(j) \geq 1 \implies N_{j+1}^* \geq KN_j^* \implies u(j)/\log j \to \infty.$$

Therefore, by (c), if $j$ is sufficiently large then

$$\mathbb{P}(Y_j \leq \lambda/2) \leq \prod_{1 \leq t \leq u(j)} \mathbb{P}
\left( |S_{U_j^*, t} - S_{U_{j,t-1}^*, t}^*| \leq \frac{1}{2} \lambda(s_{U_j^*, t} + s_{U_{j,t-1}^*, t}) \right) \]

\[ \leq \prod_{1 \leq t \leq u(j)} \mathbb{P}
\left( |S_{U_j^*, t} - S_{U_{j,t-1}^*, t}^*| \leq \lambda \sqrt{K^t N_j^*} \right) \]

\[ \leq (1 - c\lambda)^u(j) \leq \frac{1}{j^2}. \]

Thus

$$\sum_{j \geq 1} \mathbb{P}(Y_j \leq \lambda/2) < \infty.$$

Almost surely, $Y_k \leq \lambda/2$ for only finitely many $k$. 

4
Theorem 1 has an analog for Brownian motion, which follows from Theorem 1 and the invariance principle.

**Theorem 3** Let $W(t)$ be Brownian motion on $[0, \infty)$. If $f_N = (\log N)^M$ with fixed $M > 0$, then almost surely

$$I = \liminf_{N \to \infty} \max_{N < t \leq N f_N} \frac{|W(t)|}{\sqrt{t}} < \infty.$$  

If $f_N = (\log N)^{\xi(N)}$ with $\xi(N) \to \infty$, then $I = \infty$ almost surely.

Theorem 3 can be proved directly and more swiftly using the methods used to establish Theorem 1. By invariance principles (e.g. Philipp, 1986), one may deduce from Theorem 3 a version of Theorem 1 where stronger hypotheses on the $X_j$ are assumed. As it stands, now, however, Theorem 1 does not follow from Theorem 3.

### 3 Dependent random variables

The conclusions of Theorem 1 can also be shown to hold for certain sequences of weakly dependent random variables by making use of almost sure invariance principles. We assume that (d) there exists a sequence of i.i.d. normal random variables $Y_j$ with $\mathbb{E}Y_j^2 = \sigma_j^2$, defined on the same probability space as the sequence of $X_j$, and such that if $Z_n = Y_1 + \cdots + Y_n$, then

$$|S_n - Z_n| = O(s_n) \quad \text{a.s.}$$

Of course the variables $Y_j$ are dependent on the $X_j$, but not on each other. Property (d) has been proved for martingale difference sequences, sequences satisfying certain mixing conditions, and lacunary sequences $X_j = \{n_j \omega\}$ with $\inf n_{j+1}/n_j > 1$, $\omega$ uniformly distributed in $[0, 1]$ and $\{x\}$ is the fractional part of $x$. See e.g. Philipp (1986) for a survey of such results.

**Theorem 4** (i) Suppose (a), (b), and (d). If $f_N := (\log N)^M$ for some constant $M > 0$, then $I < \infty$ almost surely.

(ii) Let $\xi(N)$ tend monotonically to $\infty$ and set $f_N := (\log N)^{\xi(N)}$. Then $I = \infty$ almost surely.

By (d),

$$I = O(1) + \liminf_{N \to \infty} \max_{N < s_n \leq N f_N} |Z_n|/s_n,$$

and we apply Theorem 1 to the sequence of $Y_j$. The variable $Z_n$ is normal with variance $s_n^2$, hence (c) holds.
4 Prime factors of typical integers

Consider a sequence of independent random variables $Y_p$, indexed by prime numbers $p$, such that $\mathbb{P}(Y_p = 1) = 1/p$ and $\mathbb{P}(Y_p = 0) = 1 - 1/p$. We can think of $Y_p$ as modelling whether or not a "random" integer is divisible by $p$. As $\mathbb{E}Y_p = 1/p$, we form the centered r.v.'s $X_p = Y_p - 1/p$ (we may also define $X_j$ for non-prime $j$ to be zero with probability 1). Let

$$T_n = \sum_{p \leq n} Y_p, \quad S_n = \sum_{p \leq n} X_p.$$ 

We have $\mathbb{E}X_p^2 = (1 - 1/p)/p$, hence by Mertens’ estimate

$$s_n^2 = \sum_{p \leq n} \frac{1}{p} - \frac{1}{p^2} = \log n + O(1).$$

Here and in the sequel, $\log_k$, denotes, for integer $k \geq 2$, the $k$-fold iterated logarithm. Since $\mathbb{E}|X_p|^3 \leq 1/p$, the Lyapunov condition holds with $\delta = 1$. Then (a), (b) and (c) hold, and therefore the conclusion of Theorem 1 holds. Here take $D = \max_{n \geq 2} s_{n+1} / s_n$ since $s_1 = 0$.

Let $\omega(m, t)$ denote the number of distinct prime factors of $m$ which are $\leq t$. The sequence $\{T_n : n \geq 1\}$ mimics well the behavior of the function $\omega(m, n)$ for a "random" $m$, at least when $n$ is not too close to $m$. This is known as the Kubilius model. It can be made very precise, see (Elliott, 1979, Ch. 3, especially pp. 119–122) and Tenenbaum (1999) for the sharpest estimate known to date. Suppose $r$ is an integer with $2 \leq r \leq x$ and $r = x^{1/u}$, $\omega_r(m) = (\omega(m, 1), \ldots, \omega(m, r))$ and suppose $Q$ is any subset of $\mathbb{Z}^r$. Then, given arbitrary $c < 1$, and uniformly in $x, r$ and $Q$, we have

$$\frac{1}{x} |\{m \leq x : \omega_r(m) \in Q\}| = \mathbb{P}\left((T_1, \ldots, T_r) \in Q\right) + O\left(x^{-c} + e^{-u \log u}\right). \quad (2)$$

An analog of Theorem 1, established by parallel estimates, provides via (2) information about localized large values of

$$g(m, t) := |\omega(m, t) - \log_2 t|/\sqrt{\log_2 t}.$$ 

**Theorem 5** (i) Let $M > 0$ be fixed, $f_N := (\log N)^M$ and put $K := 30D^2 \sqrt{M + 1}$. If $g = g(m) \to \infty$ monotonically as $m \to \infty$ in such a way that $g^2 f_g \leq \log_2 m$ for large $m$, then for a set of integers $m$ of natural density 1, we have

$$\min_{g(m) \leq N \leq g(m)^2} \max_{N < \log_2 t \leq N f_N} g(m, t) \leq K.$$ 

---

2 A subset $\mathcal{A}$ of $\mathbb{N}^*$ is said to have natural density 1 if $|\mathcal{A} \cap [1, x]| = x + o(x)$ as $x \to \infty$. 

6
(ii) Let \( \xi(N) \to \infty \) in such a way that \( f_N := (\log N)^{\xi(N)} \leq N \). Suppose that \( g(m) \to \infty \) monotonically as \( m \to \infty \), that \( g(m) \leq (\log_2 m)^{1/10} \), and let

\[
I_m := \min_{g(m) \leq N} \max_{N \leq \log_2 m} g(m, t).
\]

Then, \( I_m \to \infty \) on a set of integers \( m \) of natural density 1.

We follow the proof of Theorem 1. Keeping the notation introduced there, we see that for large \( J \),

\[
\mathbb{P}\left( \bigcap_{J \leq j \leq 3J/2} A_j B_j C_j \right) \leq \sum_{J \leq j \leq 3J/2} \frac{D^2}{J^2} + \prod_{J \leq j \leq 3J/2} \left( 1 - \frac{3}{4\sqrt{j}} \right) \ll \frac{1}{J}.
\]

For large \( G \), define \( J \) by \( N_{J+1} < G \leq N_{J+2} \). Then \( G^{5/3} > N_{3J/2+2} \) and \( J \gg_M (\log G)/\log_2 G \). Thus, for large \( G \),

\[
\mathbb{P}\left( \min_{G \leq N \leq G^{5/3}} \max_{h(N) < n \leq h(N_f)} \frac{|S_n|}{s_n} \leq K \right) \geq 1 - O\left( \frac{1}{J} \right) \geq 1 - O\left( \frac{\log_2 G}{\log G} \right).
\]

The direct number theoretic analog of \( |S_n|/s_n \) is

\[
\tilde{g}(m, t) := \frac{\omega(m, t) - \sum_{p \leq t} 1/p}{\sqrt{\sum_{p \leq t} (1 - 1/p)/p}}.
\]

By (2), if \( G \) is large and \( G \leq \sqrt{\log x} \) (so that \( G^{5/3} f_{G^{5/3}} \leq (\log_2 x)^{7/8} \)), then

\[
\frac{1}{x} \left\{ m \leq x : \min_{G \leq N \leq G^{5/3}} \max_{h(N) < n \leq h(N_f)} \tilde{g}(m, t) \leq K \right\} \geq 1 - O\left( \frac{\log_2 G}{\log G} \right).
\]

Since \( \tilde{g}(m, t) = g(m, t) + O\left( 1/\sqrt{\log_2 x} \right) \), the first part of the theorem follows.

The second part is similar. Note that \( \omega(n, x) - \omega(n, x^{1/\sqrt{\log_2 x}}) \leq \sqrt{\log_2 x} \) for \( n \leq x \), and, for brevity, write \( g = g(\sqrt{x}) \). By (2) with \( u := \sqrt{\log_2 x} \), we have, for any fixed \( K \) and large \( x \),

\[
\frac{1}{x} \left\{ m \leq x : \min_{N \leq g} \max_{N \leq \log_2 m} \tilde{g}(m, t) \leq K \right\} \leq \frac{1}{x} \left\{ \sqrt{x} \leq m \leq x : \min_{N \leq g} \max_{N \leq \log_2 m} \tilde{g}(t) \leq K + 2 \right\} + \frac{1}{\sqrt{x}}
\]

\[
\leq \mathbb{P}\left( \inf_{N \leq g} \max_{N \leq \log_2 m} \frac{|S_n|}{s_n} \leq K + 2 \right) + O\left( \frac{1}{\log_2 x} \right).
\]
where $L(x) := \log_2 x - \frac{1}{2} \log_3 x$. Since $f_N \leq N$, we have $N_{j+1}^* \leq (N_j^*)^2$ in the notation of the proof of Theorem 1. The interval

$$\left[ (\log_2 x)^{1/10}, L(x)^{1/2} \right]$$

therefore contains at least one interval $J_j$. By the proof of Theorem 1, for large $x$, the probability above does not exceed $\sum_{j \geq j_0} 1/j^2 \leq 1/(j_0 - 1)$, where $j_0 \to \infty$ as $x \to \infty$.

**Remarks.** The upper bound $g^2$ of $N$ in the first part can be sharpened. By the same methods, similar results can be proved for a wide class of additive arithmetic functions $r(m, t) = \sum_{p \parallel m} r(p^a)$ in place of $\omega(m, t)$.

**Acknowledgment.** The authors are indebted to Walter Philipp for helpful discussions on the use of almost sure invariance principles.
