HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract: In this paper, static output feedback stochastic stabilization and disturbance attenuation issues for a class of discrete-time Networked Control Systems (NCSs) subject to random failures and random delays are addressed. The different random processes are modeled as Markovian chains, and the resulting closed-loop system belongs to the class of discrete-time Markovian Jump Linear Systems (MJLS). Results are formulated as matrix inequalities. A numerical algorithm based on non-convex optimization is provided and its running is illustrated on a classical example from literature.

Keywords: Fault Tolerant Control - Networked Systems- Stochastic Hybrid Systems - Markovian Jumping Parameters - Random Delays - Static Output Feedback - Linear Matrix Inequalities (LMI).

1. INTRODUCTION

Networked control systems (NCSs) are feedback control loops closed through a real-time network. That is, in NCSs, communication networks are used to exchange information and control signals (reference input, plant output, control input, etc.) between control system components (sensors, controllers, actuators, etc.). The main advantages of NCSs are low cost, reduced weight, simple installation and maintenance, and high reliability. As a result, NCSs have great potential in application in complex advanced technological systems such as manufacturing plants, vehicles, aircrafts, spacecrafts, etc. (Walsh et al., 2002). At the same time, these complex systems could have various consequences in the event of component failures. Therefore, it is very important to consider the safety and fault tolerance of such systems at the design stage. For these safety-critical systems, Fault Tolerant Control Systems (FTCS) have been developed to meet these essential objectives. FTCS have been a subject of great practical importance, which has attracted a lot of interest for the last three decades. A bibliographical review on reconfigurable fault tolerant control systems can be found in (Zhang and Jiang, 2003).

Despite the advantages and potentials, communication networks in control loops make the analysis and design of NCSs complicated. One main issue is the network-induced delays, which occur when sensors, actuators, and controllers exchange data across the network. The delays may be constant, time-varying, and in most cases, random. It is known that the occurrence of delay degrades the stability and control performances of closed-loop control systems. In (Nilsson et al., 1998), the stability analysis and control performances of NCSs were studied when the network-induced delay at each sampling instant is random and less...
than one sampling time. In (Zhang et al., 2001), the stability of NCSs was analyzed by a hybrid system approach when the induced delay is deterministic (constant or time-varying) and the controller gain is constant; and in (Lin et al., 2003), a switched system approach was used to study the stability of NCSs. In (Yu et al., 2004), the maximum of the network-induced delay preserving the closed-loop stability for a given plant and controller was considered. In (Xie and Wang, 2004), the network-induced delay is assumed to be time-varying and less than one sampling time. It is noticed that in all of the aforementioned papers, the plant is in the continuous-time domain. For the discrete-time case, in (Krtolica et al., 1992) and (Xiao et al., 2000), the network-induced random delays were modeled as Markov chains such that the closed-loop system is a jump linear system with one mode. The class of linear systems with Markovian jumping parameters has attracted increasing attention in the recent literature. Markovian jump systems are those having transition between models determined by a Markov chain. It is very appropriate to model plants whose structures are subject to random abrupt changes due to component failures or repairs, sudden environmental changes, abrupt variations of the operating point of a nonlinear plant, changing subsystem interconnections, and so on. The theory of stability, optimal control and $\mathcal{H}_2/\mathcal{H}_\infty$ control, as well as important applications of such systems, can be found in several papers in the current literature, for instance in (Boukas, 2006; Boukas, 2005; Boukas, 1999; Costa et al., 1999; de Farias et al., 2000; de Souza and Fragoso, 1993; Dragan and Morozan, 2002; Dragan et al., 2004; Ji and Chizeck, 1990; Ji and Chizeck, 1992) for continuous-time case, and (Costa et al., 2005) for the discrete-time case. Fault tolerant control issues were also considered in the same framework, for instance in (Aberkane et al., 2005; Aberkane et al., 2006b; Aberkane et al., 2006a; Mahmoud et al., 2003; Shi and Boukas, 1997; Shi et al., 2003; Srichander and Walker, 1993).

On the other hand, one of the most challenging open problems in control theory is the synthesis of fixed-order or static output feedback controllers that meet desired performances and specifications (Syrmos et al., 1997). Among all variations of this problem, this note is concerned with the problem of static output feedback stochastic stabilization and disturbance attenuation ($\mathcal{H}_\infty$ control) issues for a class of discrete-time NCSs subject to random failures, random delays and/or packet loss. Results are formulated as matrix inequalities with an equality constraint of the form $PX = I$. A numerical algorithm based on nonconvex optimization is provided and its running is illustrated on a classical example from literature.

This paper is organized as follows: Section 2 describes the dynamical model of the system with appropriately defined random processes. A brief summary of basic stochastic terms, results and definitions are given in Section 3. Section 4 addresses the stochastic stabilization and $\mathcal{H}_\infty$ control problem. In Section 5, a numerical algorithm based on nonconvex optimization is provided and its running is illustrated on a classical example from literature. Finally, a conclusion is given in Section 6.

Notations. The notations in this paper are quite standard. $\mathbb{R}^{m \times n}$ is the set of $m$-by-$n$ real matrices. $A^T$ is the transpose of the matrix $A$. The notation $X \succeq Y$ ($X \succ Y$, respectively), where $X$ and $Y$ are symmetric matrices, means that $X - Y$ is positive semi-definite (positive definite, respectively); $I$ and $0$ are identity and zero matrices of appropriate dimensions, respectively; $\mathcal{E}\{\cdot\}$ denotes the expectation operator with respect to some probability measure $P$; $L^2[0, \infty)$ stands for the space of square summable vector functions over the interval $[0, \infty)$; $\| \cdot \|$ refers to either the Euclidean vector norm or the matrix norm, which is the operator norm induced by the standard vector norm; $\| \cdot \|$ stands for the norm in $L^2[0, \infty)$; while $\| \cdot \|_{\mathcal{E}_2}$ denotes the norm in $L^2((\Omega, \mathcal{F}, P), [0, \infty))$; $(\Omega, \mathcal{F}, P)$ is a probability space. In block matrices, $*$ indicates symmetric terms: $\begin{bmatrix} A & B \\ B^T & C \end{bmatrix} = \begin{bmatrix} A \ast & B \\ B^T \ast & C \end{bmatrix}$.

2. SYSTEM MODELING

Consider the following class of dynamical systems in a given fixed complete probability space $(\Omega, \mathcal{F}, P)$:

$$\begin{align*}
    \dot{x}_{k+1} &= A(\eta_k)x_k + B_u(\eta_k)u(y_k, k) + B_w(\eta_k)w_k \\
    y_k &= C_y x_k \\
    z_k &= C_z(\eta_k)x_k + D_z(\eta_k)u(y_k, k)
\end{align*}$$

(1)

where $x_k \in \mathbb{R}^n$ is the system state, $u(y_k, k) \in \mathbb{R}^r$ is the system input, $y_k \in \mathbb{R}^q$ is the system measured output, $w_k$ is the system external disturbance which belongs to $L^2[0, \infty)$, $z_k$ is the controlled output which belongs to $L^2((\Omega, \mathcal{F}, P), [0, \infty))$ and $\{\eta_k, k \geq 0\}$ denotes the state of the random process describing the failures. It is assumed that $\eta_k$ is a measurable discrete-time Markov process taking values on a finite set $\mathcal{D} = \{1, \ldots, \nu\}$. For the failure process $\eta_k$, the known one-step transition probability from state $i$ to state $l$, $i, l \in \mathcal{D}$ is given by $\alpha_{il}$, i.e.

$$\alpha_{il} = \text{Pr}\{\eta_{k+1} = l | \eta_k = i\}$$

(2)

It is also assumed that there are random but bounded delays from the sensor to the controller (Figure–1). The mode-dependent switching static output feedback control law is
where \( \{r_{sk}\} \) is a bounded random integer sequence with \( 0 \leq r_{sk} \leq d_s < \infty \), and \( d_s \) is the finite delay bound.

**Remark 1** We can use a mode-dependent switching controller if we know the delay steps on-line, and this is the case if we use time-stamped data in the network communication. However, it is important to note that the theoretical results developed in this work remain correct for the case of mode-independent control.

If we augment the state variable

\[
\ddot{x}_k = [x'_{k}, x'_{k-1}, \ldots, x'_{k-d_s}]'
\]

where \( \ddot{x}_k \in \mathbb{R}^{(d_+1)n} \), then the closed-loop system is

\[
\begin{align*}
\dot{x}_{k+1} &= (\bar{A}(\eta_k) + \bar{B}_w(\eta_k)K(r_{sk})C_y)x_k + \bar{B}_w(\eta_k)w_k \\
y_k &= \bar{C}_y(r_{sk})x_k + \bar{C}_z(\eta_k)x_k
\end{align*}
\]

where

\[
\bar{A}(\eta_k) = \begin{bmatrix} A(\eta_k) & 0 & \cdots & 0 \\ \vdots & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \\
\end{bmatrix}, \quad \bar{B}_w(\eta_k) = \begin{bmatrix} B_u(\eta_k) \\ 0 \\ 0 \\ \vdots \\ 0 \\
\end{bmatrix}
\]

\[
\bar{C}_y(r_{sk}) = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ C_y & 0 & \cdots & 0 \\
\end{bmatrix}, \quad \bar{C}_z(\eta_k) = \begin{bmatrix} C_z(\eta_k) & 0 & \cdots & 0 \\ \vdots & \ddots & \cdots & \vdots \\ 0 & \cdots & 0 & 0 \\
\end{bmatrix}
\]

and \( \bar{C}_y(r_{sk}) \) has all elements being zero except for the \( (r_{sk} + 1) \)th block being the matrix \( C_y \).

One of the difficulties with this approach is how to model the \( r_{sk} \) sequence. One way is to model the transitions of the random delays \( r_{sk} \) as a finite state Markov process (Krtolica et al., 1992; Xiao et al., 2000; Zhang et al., 2005). In this case we have

\[
\text{Prob}\{r_{sk+1} = j \mid r_{sk} = i\} = p_{ij}
\]

where \( 0 \leq i, j \leq d_s \). This model is quite general, communication package loss in the network can be included naturally as explained below (Xiao et al., 2000). The assumption here is that the controller will always use the most recent data. Thus, if we have \( y_k - r_{sk} \) at step \( k \), but there is no new information coming at step \( k + 1 \) (data could be lost or there is a longer delay), then we at least have \( y_k - r_{sk} \) available for feedback. So, in our model of the system in Figure 1, the delay \( r_{sk} \) can increase at most by 1 each step, and we constrain

\[
\text{Prob}\{r_{sk+1} > r_{sk} + 1\} = 0
\]

However, the delay \( r_{sk} \) can decrease as many steps as possible. Decrement of \( r_{sk} \) models communication package loss in the network, or disregarding old data if we have newer data coming at the same time. Hence the structured transition probability matrix is

\[
P_s = \begin{bmatrix}
p_{00} & p_{01} & 0 & 0 & \cdots & 0 \\
p_{10} & p_{11} & p_{12} & 0 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \cdots & \vdots \\
p_{d_{-0}} & p_{d_{-1}} & p_{d_{-2}} & p_{d_{-3}} & \cdots & p_{d_{-d_s}}
\end{bmatrix}
\]

where

\[
0 \leq p_{ij} \leq 1 \quad \text{and} \quad \sum_{j=0}^{d_s} p_{ij} = 1
\]

because each row represents the transition probabilities from a fixed state to all the states. The diagonal elements are the probabilities of data coming in sequence with equal delays. The elements above the diagonal are the probabilities of encountering longer delays, and the elements below the diagonal indicate package loss or disregarding old data.

3. BASIC DEFINITIONS AND RESULTS

In this section, we will first give some basic definitions related to stochastic stability notions and then we will summarize some results about stochastic stabilizability of the discrete-time NCS subject to random failures and delays. Without loss of generality, we assume that the equilibrium point, \( x = 0 \), is the solution at which stability properties are examined. We introduce the following stability and stabilizability definitions for discrete-time jump linear system.

**Definition 1.** The system (1) with \( u_k \equiv 0, w_k \equiv 0 \), is said to be **stochastically stable**, if for every initial state \( (x_0, r_{s0}, \eta_0) \), the following holds:

\[
\mathcal{E}\left\{ \sum_{k=0}^{\infty} \| x_k(x_0, r_{s0}, \eta_0) \|^2 \mid x_0, r_{s0}, \eta_0 \right\} < \infty
\]
Definition 2. We say that system (1) (with \( w(k) \equiv 0 \)) is **stochastically stabilizable**, if for every initial state \((x_0, P_{x0}, \eta_0)\), there exists a linear static output feedback control law \( \varphi_s \) such that the closed loop system (4) is stochastically stable.

The following proposition gives a necessary and sufficient condition for the mean square stability of system (4).

**Proposition 1.** The following statements are equivalent:

i) System (4) is stochastically stabilizable by \( \varphi_s \);

ii) The matrix inequalities

\[
\begin{bmatrix}
\bar{A}_{ij} & \bar{P}_{ij} & \bar{A}_{ij} - \mathcal{P}_{ij} < 0, & \forall i \in \mathcal{D}, j \in S.
\end{bmatrix}
\]  

are feasible for some matrices \( K_j \) and \( P_{ij} > 0 \), where

\[
\bar{A}_{ij} = \tilde{A}_i + \tilde{B}_i K_j \tilde{C}_{ij}; \quad \mathcal{P}_{ij} = \sum_{i=1}^{d_x} p_{ij} \sum_{m=1}^{\nu} \alpha_{jm} p_{mj}
\]

iii) For any given \( Q = (Q_{11}, \ldots, Q_{dd}) \) with \( Q_{ij} > 0 \), there exist a unique \( P = (P_{11}, \ldots, P_{dd}) \) with \( P_{ij} > 0 \) satisfying the following coupled Lyapunov equations

\[
\begin{bmatrix}
\bar{A}_{ij} & P_{ij} & \bar{A}_{ij} - Q_{ij} = 0 & \forall i \in \mathcal{D}, j \in S.
\end{bmatrix}
\]

**Proof.** The proof of this Proposition follows the same lines as for the proof of stability results in (Costa et al., 2005; Zhang et al., 2003), except here we consider two Markovian processes, while in the aforementioned references, the authors consider a single Markov process. We conclude this section by introducing the following Lemma that will be used in the derivation of the main results of this note.

**Lemma 1.** The following statements are equivalent

i) There exists a symmetric definite positive matrix \( \mathcal{P} \) such that

\[
A^T f(\mathcal{P}) A - \mathcal{P} < 0
\]

where \( f(\mathcal{P}) > 0 \) is a matrix function of \( \mathcal{P} \).

ii) There exists a symmetric definite positive matrix \( \mathcal{P} \) and a matrix \( \bar{G} \) such that

\[
\begin{bmatrix}
-\mathcal{P} & \bar{A}^T \bar{G}' \\
* & -\bar{G} + \bar{G}' + f(\mathcal{P})
\end{bmatrix} < 0
\]

**Proof.** The proof of this lemma follows the same arguments as for the proof of Theorem 1 in (de Oliveira et al., 1999).

4. MAIN RESULTS

4.1 Stochastic Stabilization

In this section, we shall address the problem of finding all static compensators \( (\varphi_s) \), as defined in section 2, such that the closed loop system \( (\varphi_s) \) becomes stochastically stable. To this end, we use Proposition 1 to get the following necessary and sufficient conditions for the stochastic stabilizability of the system (4).

**Proposition 2.** System (4) is stochastically stabilized by \( \varphi_s \) iff there exists matrices \( K_j \), matrices \( G_{ij} \) and symmetric matrices \( \mathcal{P}_{ij} > 0, i, j > 0 \) satisfying the following coupled matrix inequalities

\[
\begin{bmatrix}
-\mathcal{P}_{ij} & \bar{A}_{ij} - \mathcal{P}_{ij} & 0 \\
* & -\bar{G}_{ij} + \bar{G}'_{ij} & \bar{G}_{ij} \mathcal{P}_{ij} \\
* & * & -\mathcal{X}
\end{bmatrix} < 0
\]

under the constraints

\[
\mathcal{P}_{ij} \mathcal{X}_{ij} = \mathcal{I}
\]

where

\[
\begin{align*}
\mathcal{X} &= \text{diag}\{\gamma_1, \gamma_2, \ldots, \gamma_{\nu}\}; \\
\gamma_1 &= [\mathcal{X}_{11}, \mathcal{X}_{12}, \ldots, \mathcal{X}_{1d}]_1; \\
&\vdots \quad \vdots \\
\gamma_{\nu} &= [\mathcal{X}_{\nu1}, \mathcal{X}_{\nu2}, \ldots, \mathcal{X}_{\nu d}]_1; \\
\Gamma_{ij} &= \sqrt{\alpha_{ij} p_{j1}}, \sqrt{\alpha_{ij} p_{j2}}, \ldots, \sqrt{\alpha_{ij} p_{jd}}; \\
&\vdots \\
\Gamma_{ij} &= \sqrt{\alpha_{ij} p_{j1}}, \sqrt{\alpha_{ij} p_{j2}}, \ldots, \sqrt{\alpha_{ij} p_{jd}}.
\end{align*}
\]

Then, if (11)-(12) are feasible, the stabilizing output feedback control law is given by

\[
u_{ik} = K_j y_k
\]

**Proof.** Let us consider the matrix inequalities given by (9). The use of Lemma 1 with \( f(\mathcal{P}_{ij}) = \mathcal{P}_{ij} \) yields

\[
\begin{bmatrix}
-\mathcal{P}_{ij} & \bar{A}_{ij} - \mathcal{P}_{ij} & 0 \\
* & -\bar{G}_{ij} + \bar{G}'_{ij} & \bar{G}_{ij} \mathcal{P}_{ij} \\
* & * & -\mathcal{X}
\end{bmatrix} < 0
\]

Notice that from (13), \( G_{ij} \) is nonsingular. Let us define \( \bar{G}_{ij} = G_{ij}^{-1} \), then by the congruence transformation

\[
\begin{bmatrix}
1 & 0 \\
0 & \bar{G}_{ij}
\end{bmatrix}
\]

and with a Schur complement operation with respect to the term \( \bar{G}_{ij} \mathcal{P}_{ij} \bar{G}'_{ij} \), the inequality (13) in turn becomes

\[
\begin{bmatrix}
-\mathcal{P}_{ij} & \bar{A}_{ij} - \mathcal{P}_{ij} & 0 \\
* & -\bar{G}_{ij} + \bar{G}'_{ij} & \bar{G}_{ij} \mathcal{P}_{ij} \\
* & * & -\mathcal{X}
\end{bmatrix} < 0
\]

then, the proof is complete.

4.2 The \( H_\infty \) Control Problem

In this section, we deal with the design of controllers that stochastically stabilize the closed-loop system and guarantee the disturbance rejection, with a certain level \( \gamma_\infty > 0 \). This problematic is addressed under a nonconvex optimization framework.
In order to put the $\mathcal{H}_\infty$ control problem in a stochastic setting, we bring to bear the space $L^2((\Omega, \mathcal{F}, P), [0, \infty))$ of $\mathcal{F}$-measurable processes, $z_k$, for which

$$
\| z \|_{L_2} = \mathbb{E} \left\{ \sum_{k=0}^{\infty} z_k^T z_k \right\}^{1/2} < \infty
$$

The stochastic $\mathcal{H}_\infty$ control problem can be stated as follows:

For a given level on the $\mathcal{H}_\infty$ norm, $\gamma_\infty$, find stabilizing static output feedback gains $K_j$ such that

$$
\mathbb{E} \left\{ \sum_{k=0}^{\infty} z_k^T z_k \right\} < \gamma_\infty^2 \sum_{k=0}^{\infty} w_k^T w_k
$$

i.e.

$$
\| z \|_{L_2} < \gamma_\infty \| w \|_2
$$

In this situation, the closed loop system (4) is said to have an $\mathcal{H}_\infty$ performance level $\gamma_\infty$ over $[0, \infty)$.

Before introducing our result on $\mathcal{H}_\infty$ control for this class of stochastic hybrid systems, let us consider the following proposition which is obtained as a special case of the bounded real lemma of discrete time Markovian jump linear systems (Zhang et al., 2003).

**Proposition 3.** The system (4) is stochastically stable and $\| \varphi_{ci} \|_\infty < \gamma_\infty$ if and only if there exist matrices $K_j$ and symmetric matrices $P_{ij} > 0$ satisfying the following coupled matrix inequalities

$$
\begin{bmatrix}
A_{ij}' P_{ij} A_{ij} - P_{ij} + C_{z_{ij}}' C_{z_{ij}} & A_{ij}' P_{ij} B_{w_{ij}} \\
B_{w_{ij}}' P_{ij} B_{w_{ij}} & - (\gamma_\infty^2 I - B_{w_{ij}}' P_{ij} B_{w_{ij}})
\end{bmatrix} < 0
$$

where

$$
C_{z_{ij}} = \tilde{C}_{z_{ij}} + D_z K_j \tilde{C}_{y_{ij}}
$$

Proof. The matrix inequalities (16) can be equivalently written as follows

$$
\begin{bmatrix}
\tilde{A}_{ij}' & \tilde{B}_{w_{ij}}' \\
0 & \tilde{C}_{z_{ij}}
\end{bmatrix} \tilde{P}_{ij} \begin{bmatrix}
A_{ij} & B_{w_{ij}} \\
0 & \gamma_\infty^{-1} I
\end{bmatrix} - \begin{bmatrix}
0 & 0 \\
\gamma_\infty^{-1} & 0
\end{bmatrix}
$$

The use of Lemma 1 with $f(P_{ij}) = \tilde{P}_{ij}$ yields

$$
- \mathcal{L}_{ij} \begin{bmatrix}
\tilde{A}_{ij}' & \tilde{B}_{w_{ij}}' \\
0 & \tilde{C}_{z_{ij}}
\end{bmatrix} G_{ij}' + - G_{ij} - G_{ij}' < 0
$$

then by the congruence transformation

$$
\begin{bmatrix}
1 & 0 \\
0 & G_{ij}
\end{bmatrix}
$$

and with a Schur complement property, we obtain (17). Hence, the proof is complete. □

5. COMPUTATIONAL ISSUES AND EXAMPLE

5.1 A Cone Complementarity Algorithm

The necessary and sufficient conditions derived in Proposition 2 and Proposition 4 are formulated as LMI feasibility problem under equality constraints of the form $P_{ij} X_{ij} = I$. The numerical example is solved using a first order iterative algorithm. It is based on a cone complementarly (CCL) technique (Ghaoui et al., 1997), that allows to concentrate the non convex constraint in the criterion of some optimisation problem.

For $P = (P_{11}, \ldots, P_{ij}, \ldots, P_{vd})$, $G = (G_{11}, \ldots, G_{ij}, \ldots, G_{vd})$, $K = (K_1, \ldots, K_j, \ldots, K_d)$ and $X = (X_{11}, \ldots, X_{ij}, \ldots, X_{vd})$, define two convex sets by a set of LMIs as

$$
\mathcal{C}^r_{(P, G, K, X)} \triangleq \{(P, G, K, X) : \text{LMIs}(11), P_{ij} > 0, X_{ij} > 0, \}
$$

and

$$
\mathcal{C}^l_{(P, G, K, X)} \triangleq \{(P, G, K, X) : \text{LMIs}(17), P_{ij} > 0, X_{ij} > 0, \}
$$

It can be seen from Proposition 4 (resp. Proposition 2) that the $\mathcal{H}_\infty$ control problem (resp. stochastic stabilization) of the system (4) is solved iff there exist $P = (P_{11}, \ldots, P_{ij}, \ldots, P_{vd})$, $G = (G_{11}, \ldots, G_{ij}, \ldots, G_{vd})$, $K = (K_1, \ldots, K_j, \ldots, K_d)$ and $X = (X_{11}, \ldots, X_{ij}, \ldots, X_{vd})$ such that

$$
(P, G, K, X) \in \mathcal{C}^r_{(P, G, K, X)}, P_{ij} X_{ij} = I, \forall i \in \mathcal{I}, j \in S
$$

(21)
is feasible.

The CCL algorithm is based on the fact that for any matrices $X > 0$ and $P > 0$ ($X, P \in \mathbb{R}^{n \times n}$), if the LMI
\[
\begin{bmatrix}
X & I \\
I & P
\end{bmatrix} \succeq 0
\]
is feasible, then $\text{tr}(PX) \geq n$, and $\text{tr}(PX) = n$ if and only if $PX = I$. Hence a feasible solution of (21) (resp. (22)) can be obtained from the solution of the following nonconvex optimization problem
\[
\min_{(P,G,K,X) \in C^{\infty}_{(P,G,K,X)}} \left\{ \text{tr}(XP) : \begin{bmatrix} X_{ij} & I & P_{ij} \end{bmatrix} \succeq 0 \right\}
\]  
(resp. \( (25) \)) satisfies
\[
\text{tr}(XP) = \nu \times (d_x + 1)^2 \times n
\]
then (21) (resp. (22)) is feasible. Hence, the $\mathcal{H}_\infty$ control problem (resp. stochastic stabilization) of the system (4) is now changed to a problem of finding a global solution of the minimization problem (24) (resp. (25)). This is however, still a difficult issue since the objective function is nonconvex. The CCL algorithm can find the global solutions of problems like (24) (resp. (25)) most of the time (de Oliveira and Geromel, 1997).

**CCL Algorithm:** For a given $\gamma_\infty > 0$

1. **Feasibility.** $h = 0$: start from a point $(P_0,G_0,K_0,X_0) \in C^{\infty}_{(P,G,K,X)}$;
2. set $V_h = P_h$ and $W_h = X_h$. Define the linear function
\[
f_h(P,X) = \text{tr}(V_hX + W_hP)
\]
3. find $(P_{h+1}, X_{h+1})$ solving the following convex programming
\[
\min_{(P,G,K,X) \in C^{\infty}_{(P,G,K,X)}} \left\{ f_h(P,X) : \begin{bmatrix} X_{ij} & I & P_{ij} \end{bmatrix} \succeq 0 \right\}
\]
4. if $f_h$ converges, then exit. Otherwise, set $h = h + 1$ and go to step ii).

The first step of the algorithm and every step ii) are simple LMI problems. There are many algorithms for these problems, especially, interior-point methods.

### 5.2 Numerical example

In this section, the proposed static output feedback $\mathcal{H}_\infty$ control of the NCS subject to random failures is illustrated using a VTOL helicopter model (Jiang and Chowdhury, 2005). The sampling time is $T_s = 0.01s$, and the random sensor delay exists in $t_x \in \{0,1\}$, and its transition probability matrix is given by
\[
[p_{ij}] = \begin{bmatrix} 0.9 & 0.1 \\ 0.9 & 0.1 \end{bmatrix}
\]
Consider the nominal system with
\[
A = \begin{bmatrix} 0.9996 & 0.00027 & 0.0001646 & -0.004557 \\
0.0004794 & 0.99 & -0.0001761 & -0.004001 \\
0.0009995 & 0.005004 & 0.9931 & 0.02527 \\
5.002e-006 & 2.509e-005 & 0.009965 & 1 \end{bmatrix}
\]
\[
B_u = \begin{bmatrix} 0.004432 & 0.001754 \\
0.05087 & -0.07554 \\
-0.05488 & 0.04455 \\
-0.0002749 & 0.0002233 \end{bmatrix},
\]
\[
B_w = \begin{bmatrix} 0.1 & 0 \\
0 & 0 \\
0 & 0 \\
0.1 & 0 \end{bmatrix}
\]
\[
C_y = \begin{bmatrix} 1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \end{bmatrix} : C_z = \begin{bmatrix} 0 & 1 & 0 \end{bmatrix} ; D_z = \begin{bmatrix} 1 & 0 \end{bmatrix}.
\]

The state vector $x_k \in \mathbb{R}^4$ is composed by the following:
\[
x_1: \text{longitudinal velocity};
\]
\[
x_2: \text{vertical velocity};
\]
\[
x_3: \text{rate of pitch};
\]
\[
x_4: \text{pitch angle}.
\]

and the components of command vector are:
\[
u_1: \text{general cyclic command};
\]
\[
u_2: \text{longitudinal cyclic command}.
\]

For illustration purposes, we will consider the following faulty modes:

1. **Mode 2:** A total loss of the actuator 2;
2. **Mode 3:** A total loss of the actuator 2 and a 50% power loss on the first actuator.

From above, we have that $S = \{1, 2, 3\}$, where the mode 1 represents the nominal case. The failure process is assumed to have Markovian transition characteristics. The actuator failure transition probability matrix is assumed to be:
\[
[p_{ij}] = \begin{bmatrix} 0.90 & 0.05 & 0.05 \\
0 & 0.95 & 0.05 \\
0 & 0 & 1 \end{bmatrix}
\]

For the above NCS, and using the CCL algorithm with $\gamma_\infty^2 = 10$, we obtain the following controllers:
\[
K_1 = \begin{bmatrix} 0.0006 & -1.5287 \\
-0.1081 & 4.6208 \end{bmatrix},
K_2 = \begin{bmatrix} -0.0045 & -1.0311 \\
0.0200 & -0.3933 \end{bmatrix}.
\]

The state trajectories of the closed loop system resulting from the discretized model and the obtained controller are shown in Figure 2. These trajectories represent a single sample path simulation corresponding to a realization of the failure process.
\( \eta_k \) and the random delay process \( r_{x_k} \). Figure 3 represents the evolution of the controlled outputs \( z_k \). It can be seen that the closed-loop system is stochastically stable and that the disturbance attenuation is achieved.

6. CONCLUSION

In this paper, static output feedback stochastic stabilization and disturbance attenuation issues for a class of discrete-time Networked control systems (NCSs) subject to random failures and random delays was addressed under the discrete-time Markovian Jump Linear Systems framework. Results are formulated as matrix inequalities, one of which is nonlinear. The numerical resolution of the obtained results was done using a cone complementary algorithm. The effectiveness of the developed method was illustrated on a classical example from literature.
