## Abstract

In component-based software development approaches, components are considered as black boxes, communicating through required and provided interfaces which describe their visible behaviors. In the best cases, the provided interfaces are checked to be compatible with the corresponding required interfaces, but in general, adapters have to be introduced to connect them. We propose to exploit existing notations and languages with their associated tools to specify working systems out of components : UML composite structure diagrams to express the architecture in terms of components and their interfaces, class diagrams, sequence diagrams and protocol state machines to describe the behavior of each component. Component interfaces will then be expressed in B in order to verify the interoperability. The use of B assembling and refinement mechanisms eases the verification of the interoperability between interfaces and the correctness of the component assembly.

**Keywords:** component-based development, provided interface, required interface, interoperability, compatibility, adaptation, assembly

## 1 Introduction

Recent works have shown that assembling components independently produced and taking into account the verification of their assembly with appropriate tools is a promising approach [Szy99]. The underlying idea is to develop software systems by assembling existing parts, as it is common in other engineering disciplines. Among the advantages of such approaches, we can cite: (i) reusability of trustworthy software components, (ii) reduction of the development costs due to the reusability, and (iii) flexibility of systems developed by this approach. But, assembling components is not currently well supported by standard design methods nor adapted to critical applications. On one hand, current technologies of components [OMG06, Sun06, Mic, W3C] do not take into account safety requirements, on the other hand, development and certification processes of critical software, based on formal methods, is not well suited to component-based approaches.

The development of component-based systems introduces a fundamental evolu-

tion in the way systems are acquired, integrated, deployed and modified. Systems are designed by examining existing COTS (Commercial Off-The-Shelf) components to see how they meet the expected requirements and decide how they can be integrated to provide the expected functionalities. Next, the system is engineered by assembling the selected components with some locally developed pieces of code.

As components are COTS, they are seen as black-boxes units which only specify interfaces and explicit dependencies. An interface describes services offered and required by a component without disclosing the component implementation. Component interfaces are the only access to component informations and functionalities. The services offered by a component are described by provided interfaces and the needed services are described by required interfaces.

For different COTS components to be deployed and to work together, they must interoperate : their interfaces must be compatible through different levels of compatibility depending on the requirements of the developed system. The syntactic level covers signature aspects of attributes and methods provided or required by the interfaces whereas the semantic level concerns behavioral aspects of the considered methods and the protocol level covers the allowed sequence of method calls.

The availability of formal languages and tool support for specifying interfaces and checking their compatibility is necessary in order to verify the interoperability of components. The idea to define component interfaces using B has been introduced in an earlier paper [CS05] : semantics and protocols of the component services can be easily modeled using the B formal method. The use of the B refinement [Abr96] to prove that two components are compatible at the signature and semantics levels has been explored in [CHS06]. To guarantee a trustworthy assembly of components, each connection of a required interface with another provided interface has to be considered. In the best cases, the provided interface constitutes an implementation of the required interface. In general cases, to construct a working system out of components, adapters have to be defined [MLS06]. An adapter is seen as a new component that realizes a required interface using a provided interface. At the signature level, it expresses the mapping between required and provided variables and at the behavioral and protocol levels, it expresses how the required methods are implemented in terms of the provided ones.

In this paper, we generalize the previous results, taking into account a more general assembly of components with the use of both cases of interfaces for different components to be connected. We use the following notations:

- UML 2.0 [OMG05] composite structure diagrams serve to express the overall architecture of the system in terms of components and interfaces.
- UML 2.0 class diagrams serve to express interface data model with its different attributes and operations.

- The usage protocol of each interface can be modeled by a Protocol State Machine (PSM).
- UML 2.0 sequence diagrams serve to express the interactions between the components to be connected.
- The use of the formal method B [Abr96] and its associated tools serve to specify interfaces, giving a special attention to correctness, increasing confidence in the developed systems: correctness of specifications, as well as correctness of the followed process with verification aspects.

In the following, we present the case study of a simple access control system defined in terms of components with a special focus on the identification component, itself defined in terms of components. Section 3 exposes the trustworthy assembly problem in a general manner. Section 4 presents a simple case of trustworthy component assembly. Section 5 presents a more general case of component assembly. Some related works are discussed in Section 6 and Section 7 concludes the paper.

## 2 Case Study: a Simple Access Control System

We illustrate our purpose with the case study of a simple access control system which manages the access of authorized persons to existing buildings [Afa00]. Persons who are authorized to enter the building have to be identified. The needed authentication informations may be stored on an electronic access card or a sophisticated key or a bar code pass, etc. Turnstiles block the entrance and the exit of each building until an authorization is given whereas identification systems are installed at each entrance and exit of the concerned buildings. The means of identification can be read to kept out the authentication informations. It can be inserted and ejected and must be taken by the user before a fixed time of 30 seconds, else it is retracted and kept by the system.

A partial view of the architecture of the access control system is given Figure 1 as a UML 2.0 composite structure diagram. Such diagrams contain named rectangles corresponding to the components of the system; here, we have depicted four components : the **AccessControl** component corresponding to the system requirements, an **Identification** component corresponding to the control of the identification, a **Database** component which is a passive component knowing informations about the authorization of each concerned user and a **Turnstile** component. They are connected by means of interfaces which may be required or provided. Required interfaces explicit the context dependencies of a component and are denoted using the “socket” notation whereas provided interfaces explain which functionalities the considered component provides and are denoted using the “lollipop” notation.

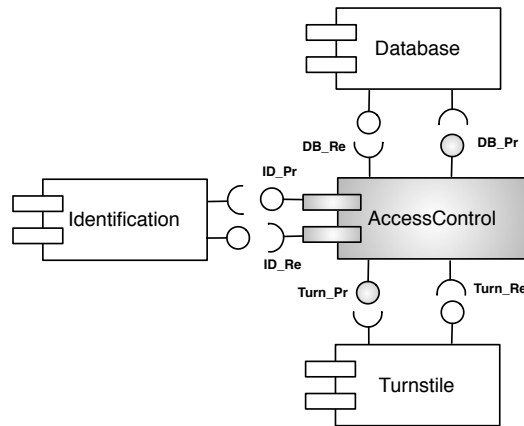

Figure 1: Partial view of the architecture of the access control system

We will focus on the interactions between the **AccessControl** and the **Identification** components. Requirements concerning the **Identification** component are expressed by the two interfaces of the **AccessControl** component. They have been outlined in Figure 2; they are modeled by class diagrams with their different attributes and methods :

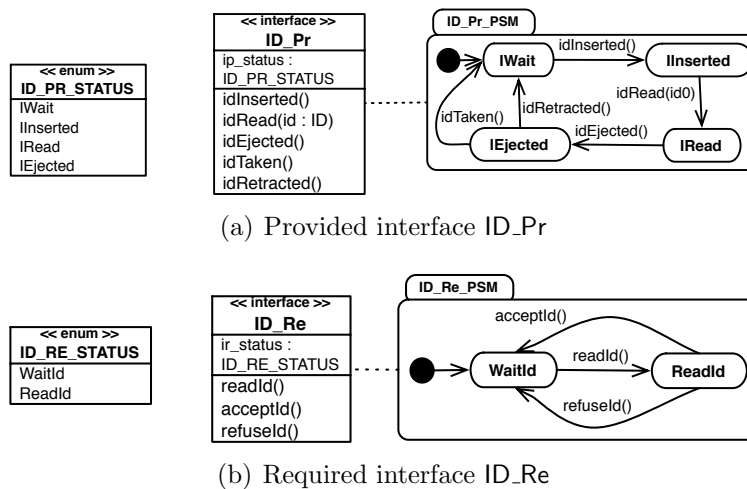

Figure 2: Interfaces of AccessControl related to Identification

- ID\_Pr corresponds to its provided interface related to the **Identification** component with five operations: `idInserted`, `idRead` parameterized by some authentication informations represented by `id`, `id Ejected`, `idTaken` and `idRetracted`.
- ID\_Re corresponds to its required interface which must be provided by an **Identification** component with three operations, `readId`, `acceptedId` and `refusedId`.

Enumerated data types are defined using the stereotype “enum”. The usage protocol of each interface is modeled by a Protocol State Machine (PSM) as presented Figure 2. A PSM specifies the external behavior of the component, with the order of the allowed method calls starting from its initial state.

**The B method.** It is a formal software development method based on set theory which supports an incremental development process, using refinement [Abr96]. A development begins with the definition of an abstract model, which can be refined step by step until an implementation is reached. The refinement of models is a key feature for incrementally developing models from textual descriptions, preserving correctness in each step.

The method has been successfully applied in the development of several complex real-life applications, such as the METEOR project [BBM99]. It is one of the few formal methods which has robust and commercially available support tools for the entire development life-cycle from specification down to code generation [BBP<sup>+</sup>03]. The B method provides structuring primitives that allow one to compose machines in various ways. Large systems can be specified in a modular way and in an object-based manner [MS99, LS01]. Proofs of invariance and refinement are part of each development. The proof obligations are generated automatically by support tools such as AtelierB [ste98] or B4free [Cle04], an academic version of AtelierB. Checking proof obligations with B support tools is an efficient and practical way to detect errors introduced during development.

For each interface of Figure 2, we give a B model as presented Figure 3: each model consists of a set of variables, invariant properties of those variables and operations. The state of the model, i.e. the set of variables values, is modifiable by operations, which must preserve its invariant:

- in the ID\_Pr model, the variable `id_status` has four possible states and its initial state is `IWait`. After an `idInserted()` call, its state is changed to `IInserted`,
- the ID\_Re model expresses the required behaviors of the card reader. A variable, namely `ip_status`, gives its state, which is initialized with `WaitId`.

In an integrated development process, the B models can be obtained by applying systematic derivation rules from UML to B [MS99, LS02].

Our purpose is to define the `AccessControl` component using COTS, i.e. existing components available on the market.

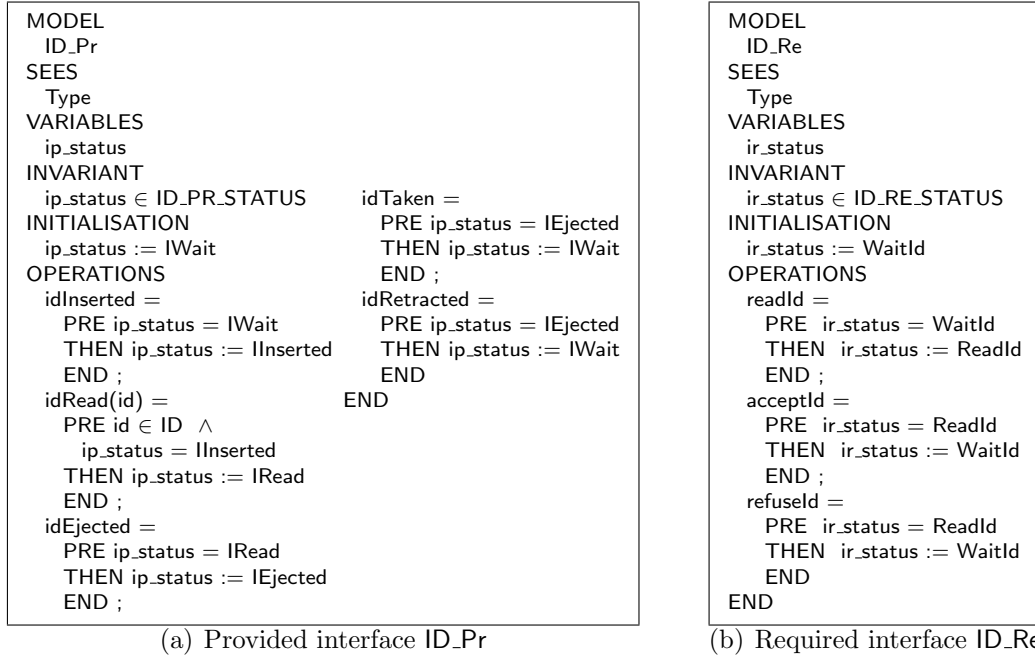

Figure 3: B Models for the interfaces of AccessControl

### 3 Component Trustworthy Assembly

Components must be assembled in an appropriate way. Interoperability means the ability of components to communicate and to cooperate despite differences in their implementation language, their execution environment, or their model abstraction [YS97]. Two components are interoperable if all their interfaces are compatible [CHS06]. More precisely, it means that, for each required interface of a considered component, there exists a compatible interface which is provided by another existing component. Three main levels of interfaces compatibility are considered and checked:

- the syntactic level covers static aspects and concerns the interface signature. Each attribute of the required interface must have a counterpart in the provided one; for each method of the required interface, there exists an operation of the provided interface with the same signature,
- the semantic level covers behavioral aspects,
- the protocol level deals with the expression of functional properties (like the order in which a component expects its methods to be called).

A provided interface can propose more functionalities (attributes, methods, behaviors, protocols, etc.) than the required one needs, but all the functionalities used

by the required interface must be proposed by the provided one. The process of proving interoperability between components is described in [CHS06].

Often, to construct a working assembly out of components, adapters have to be defined, connecting the required interfaces to the provided ones. An adapter is a new component that realizes the required interface using the provided interface. At the signature level, it expresses the mapping between required and provided variables. At the behavioral and protocol levels, it expresses how the required operations are implemented in terms of the provided ones. In [MLS06], we have studied the adapter specification and its verification using B. We have given a B model of the adaptation that must refine the B model of the required interface including the provided incompatible interface.

More generally, the component assembly concerns the use of both type of interfaces for different components to be connected. We show that the component assembly is a generalization of the adaptation problem : a new specific component is introduced to manages the needed components. It realizes all the required interfaces of the considered components using their provided interfaces.

## 4 A Simple Case of Component Trustworthy Assembly

Let us use a COTS component `Identification1` whose description is given Figure 4 to answer the requirements of `AccessControl` presented Section 2. It is a card reader equipped with two lights, a green one and a red one. These lights indicate if the authorization has been accepted (the green light turns on) or denied (the red light turns on). The two lights cannot be turned on at the same time.

Figure 4: An existing component `Identification1`

The component `Identification1` is equipped with two interfaces:

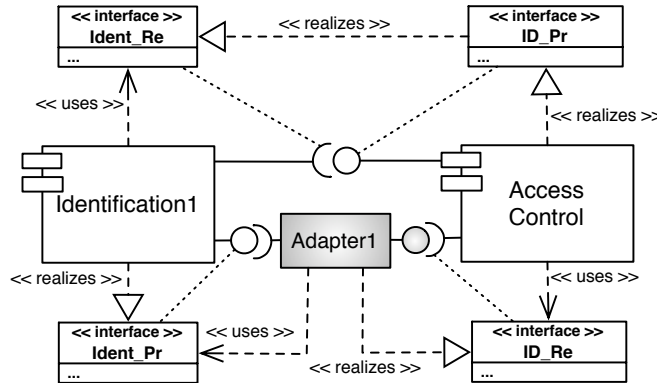

- Its provided interface, namely **Ident\_Pr**, related to a system controller. Its two variables **green** and **red** give the state of two lights: the green light must be turned on if the authorization has been accepted (**acceptIdent**), otherwise the red light must be turned on (**refusIdent**). An invariance property expresses that the two lights cannot be turned on at the same time, as expressed in the B model given Figure 5.
- Its required interface **Ident\_Re**, related to a system controller which is similar to the **ID\_Pr** provided interface of the **AccessControl** component previously defined.

MODEL	INITIALISATION	
Ident_Pr	green := On,	acceptIdent =
SEES	red := Off	PRE green = Off $\wedge$ red = Off
Type		THEN green := On
VARIABLES	OPERATIONS	END ;
green, red	readIdent =	refusIdent =
INVARIANT	PRE green $\neq$ red	PRE green = Off $\wedge$ red = Off
green $\in$ SWITCH $\wedge$	THEN	THEN red := On
red $\in$ SWITCH $\wedge$	green := Off	END
$\neg$ (green = On $\wedge$ red = On)	red := Off	END
	END ;	END

Figure 5: B Model of the interface **Ident\_Pr** of **Identification1**

To ensure that the assembly of components **Identification1** and **AccessControl** is trustworthy [MLS06], we must prove that the corresponding interfaces are compatible, see Figure 6. We decompose this proof into two steps.

Figure 6: **Identification1** and **AccessControl** assembly

#### 4.1 Compatibility between **Ident\_Re** and **ID\_Pr**

We have to prove that **ID\_Pr** *realizes* **Ident\_Re**. This property can be expressed by the B refinement concept as presented Figure 7. When using B4free, we prove that

the B model of `ID_Pr` is a correct refinement of the B model of `Ident_Re`. That means that the methods of the provided interface implement directly the methods of the required interface. In this example, the proof of this refinement is obvious.

Figure 7: B compatibility between `Ident_Re` and `ID_Pr`

We conclude that the required interface `Ident_Re` of the component `Identification1` is compatible with the provided interface `ID_Pr` of the `AccessControl` component. The interoperability is verified at the signature, semantic and protocol levels.

## 4.2 Adaptation between `ID_Re` and `Ident_Pr`

When looking at the required interface `ID_Re` of the component `AccessControl`, as expressed Figure 2, it is obvious that it is not directly compatible with the interface `Ident_Pr` of the component `Identification1`, see Figure 4. We propose to introduce a new component, called `Adapter1`, to map correctly these two incompatible interfaces. In terms of UML, this new component *realizes* `ID_Re`, *using* `Ident_Pr`.

The correction of this adaptation can be proved using the B method. It is expressed by the schema presented Figure 8, in which `Adapter1` is modeled by a refinement which:

- *refines* the B model of the required interface `ID_Re` and
- *includes* the B model of the provided interface `Ident_Pr`.

Figure 8: B adaptation between `ID_Re` and `Ident_Pr`

The B model of the component `Adapter1` proposed Figure 9 expresses the mapping between the two interfaces. The invariant clause, or gluing invariant, makes the correspondence between the required and the provided attributes. The variable

REFINEMENT	OPERATIONS
Adapter1	readId =
REFINES	BEGIN
ID_Re	readIdent
SEES	END ;
Type	acceptId =
INCLUDES	BEGIN
Ident_Pr	acceptIdent
INVARIANT	END ;
((green $\neq$ red)	refuseId =
$\Rightarrow$ ir_status = WaitId)	BEGIN
$\wedge$ ((green = red = Off)	refuseIdent
$\Rightarrow$ ir_status = ReadId)	END
	END

Figure 9: B Model for the component Adapter1

ir\_status required by the access control is defined in terms of the two variables **green** and **red** provided by the identification. The operation clause defines how the required methods, i.e. **readId**, **acceptId** and **refuseId** are implemented by the provided ones, **readIdent**, **acceptIdent** and **refuseIdent**.

The proof of this refinement is obvious. As a consequence, **Adapter1** implements **ID\_Re** in terms of **Ident\_Pr**. We are able to assemble **Identification1** to **AccessControl** through **Adapter1**.

## 5 A General Case of Component Trustworthy Assembly

Let us define an identification component corresponding to the previous requirements given section 4 in terms of three existing COTS components, namely **CardReader**, **Timer** and **MultiLights**. The component **CardReader** is used to read the authentication informations on an access card and the component **Timer** to indicate the time limit. Green and red lights are provided by the component **MultiLights**.

The general case of component assembly concerns the use of both type of interfaces for different components to be connected. A new specific component is defined to manages these components. It **realizes** all the required interfaces of the considered components **using** their provided interfaces.

### 5.1 Existing COTS components

The functionality of each component is known by its interface descriptions presented below as UML 2.0 diagrams associated to B models for behavioral and protocol specifications.

**The component CardReader.** This component reads identification informations from an access card. It is equipped with two interfaces, as presented Figure 10, a provided one named `Card_Pr` with three methods (`readCard()`, `ejectCard()` and `retractCard()`) and a required one named `Card_Re` which receives messages from its controller by the way of five methods.

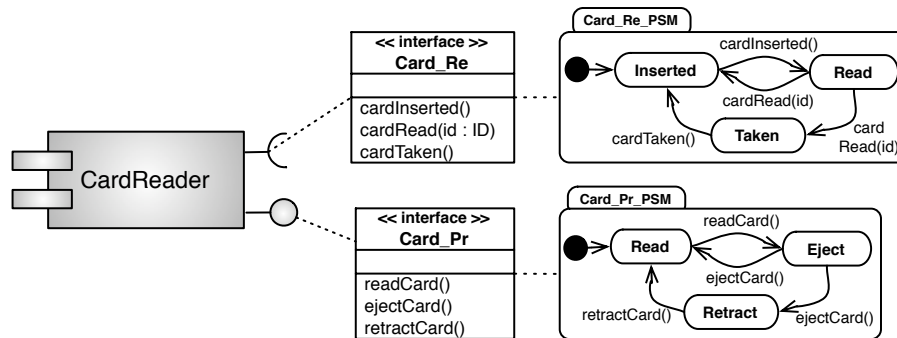

Figure 10: Component `CardReader` and its interfaces `Card_Pr` and `Card_Re`

**The component Timer.** As presented Figure 11, this component has two interfaces. The provided one, `Timer_Pr`, offers two functionalities: it can be started with a fixed time and interrupted before the timeout is reached. When the timeout is reached, the timer sends this information through its required interface `Timer_Re`.

Figure 11: Component `Timer` and its interfaces `Timer_Pr` and `Timer_Re`

**The component MultiLights.** This component presented Figure 12 is a light box that proposes several color lights. It offers, by the way of its provided interface `MLight_Pr`, the next functionalities: the chosen light can be turned on and turned off. When the light is turned off, one can choose a light color from predefined ones.

## 5.2 The component Identification2

A component `Identification2` can be defined by assembling these three existing components, as depicted Figure 13 in order to fulfill the requirements. The required

Figure 12: Component MultiLights and its provided interface MLight\_Pr

and provided interfaces Ident\_Re and Ident\_Pr of Identification2 have to be defined in terms of the components CardReader, Timer and MultiLights through their interfaces Card\_Re, Card\_Pr, Timer\_Re, Timer\_Pr and MLight\_Pr.

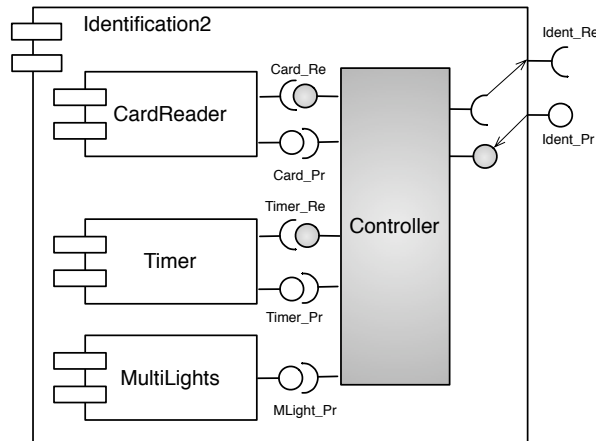

Figure 13: Architecture of the component Identification2

A “new” component Controller is introduced to manage the interactions between all these interfaces. Identification2 *delegates* to Controller its interfaces Ident\_Re and Ident\_Pr:

- Controller realizes for Identification2 the interface Ident\_Pr, and
- Controller uses through Identification2 the interface Ident\_Re.

Figure 14 shows the sequence of operation calls between all the components to be assembled to produce Identification2.

To prove that the assembly of CardReader, Timer and MultiLights through Controller is correct, we must prove that Controller:

- *realizes* the provided interface Ident\_Pr delegated by Identification2,
- *realizes* the required interface Card\_Re of CardReader,

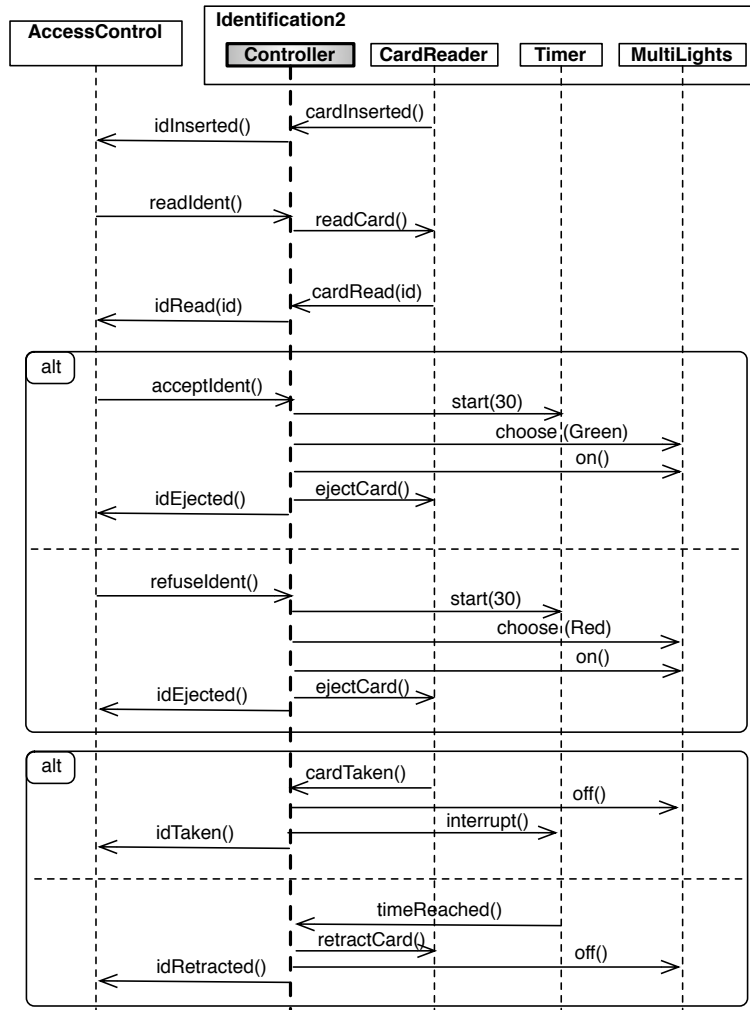

Figure 14: Sequence diagram for the Identification2 component

- *realizes* the required interface `Timer_Re` of `Timer`,
- *using* the provided interfaces `Card_Pr`, `Timer_Pr` and `MLight_Pr` of the three existing components, and the required interface `Ident_Re` delegated by `Identification2`.

This UML2.0 architecture can be expressed by the B architecture given Figure 15 with two levels of refinement:

- the B abstract model, `Controller_abs`, which *extends* all the interfaces to be realized,
- the B refinement model, `Controller`, which
  - *includes* all the interfaces to be used, and
  - *refines* the abstract model `Controller_abs`.

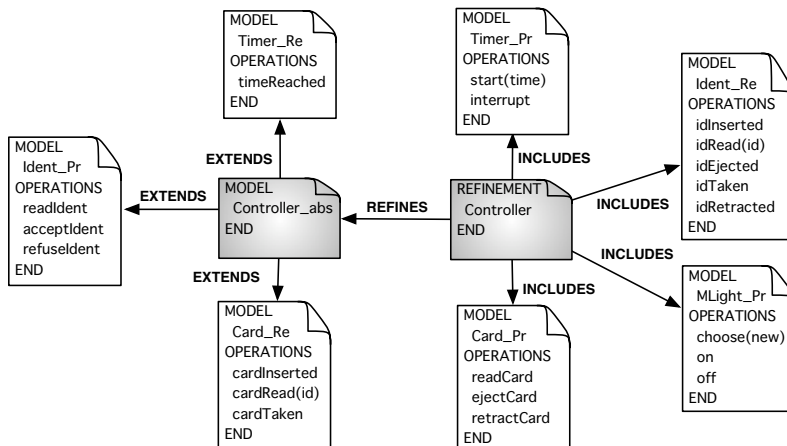

Figure 15: B architecture of the component `Controller`

The B refinement model `Controller` of the example is given Figure 16:

- the available components are included, i.e. `Ident_Re`, `Card_Pr`, `Timer_Re` and `MLight_Pr`
- its gluing invariant expresses how to obtain the required attributes `green` and `red` from the attributes `color` and `switch` of the provided interfaces,
- the operations clause describes all the needed methods in terms of the used ones.

Let us consider the needed method `acceptIdent()` of the `Ident_Pr` interface of `Identification2`. This method is called when an inserted card has been authorized to enter the building. The required result, as expressed in the sequence diagram of Figure 14 must be that a green light is turned on during a fixed time and the card is ejected. This requirement is expressed in the B operation by:

- a timer is started: `start(30)`,
- the light's color is fixed to green, `choose(green)` before the light is turned on, on,
- the card is ejected, `ejectCard`, and
- the environment is informed, `isEjected`.

<pre> REFINEMENT   Controller REFINES   Controller_abs SEES   Type INCLUDES   Ident_Re, Card_Pr,   Timer_Pr, MLight_Pr INVARIANT   ((color = Green ^ switch = On)    =&gt; green = On)   ^ (¬(color = Green ^ switch = On)      =&gt; green = Off)   ^ ((color = Red ^ switch = On)      =&gt; red = On)   ^ (¬(color = Red ^ switch = On)      =&gt; red = Off) </pre>	<pre> OPERATIONS   /* Ident_Pr */   readIdent =   BEGIN     readCard   END ;   acceptIdent =   BEGIN     start(30)        BEGIN       choose(Green) ; on     END        ejectCard        idEjected   END ; </pre>	<pre> refusIdent =   BEGIN     start(30)        BEGIN       choose(Red) ; on     END        ejectCard        idEjected   END ; /* Timer_Re */ timeReached =   BEGIN     retractCard        off        idRetracted   END ; </pre>	<pre> /* Card_Re */ cardInserted =   BEGIN     idInserted   END ; cardRead(id) =   BEGIN     idRead(id)   END ; cardTaken =   BEGIN     off        interrupt        idTaken   END ; </pre>
---	---	--	--

Figure 16: B Model of the component `Controller`

The B prover generates 168 trivial proof obligations and 30 non-trivial ones which are automatically proved. We conclude that the proposed component `Controller` is a correct implementation of the required functionalities in terms of the three existing components. With the B prover, we check

- that `Controller` refines all the required interfaces. This guarantees that the required behavioral and protocol aspects are preserved by the assembling. Of course, the signature level is also considered,
- the correctness of the use of the provided interfaces by the inclusion of their B interface models.

## 6 Related Works

In an earlier paper [HHS06], we have investigated the necessary ingredients a component specification must have in order to be useful for assembly of a software system out of components. These ingredients are independent of concrete component models. We have proposed a method consisting of four steps to guide this process.

Several proposals for verifying the interoperability between components have been made. In [EF02], Estevez and Fillotrani analyze how to apply algebraic specifications with refinement to component development, with a restriction to the use of modules that are described as class expressions in a formal specification language. They present several refinement steps for component development, introducing in each one design decisions and implementation details.

Our work focuses on the verification of interoperability of components through their interfaces using B assembling and refinement mechanisms.

Zaremski and Wing [ZW97] propose an approach to compare two software components. They determine whether one required component can be substituted by another one. They use formal specifications to model the behavior of components and exploit the Larch prover to verify the specification matching of components.

In [CFP<sup>+</sup>01], a subset of the polyadic  $\pi$ -calculus is used to deal with the component interoperability at the protocol level.  $\pi$ -calculus is a well suited language for describing component interactions. Its main limitation is the low-level description of the used language and its minimalistic semantic. In [Han98, Han00], protocols are specified using a temporal logic based approach, which leads to a rich specification for component interfaces. Henzinger and Alfaro [AH01] propose an approach allowing the verification of interfaces interoperability based on automata and game theories: this approach is well suited for checking the interface compatibility at the protocol level. In [BCH05], the three levels of interface compatibilities are considered on web service interfaces described by transition systems.

Several proposals for component adaptation have already been made. The need of adaptation and assembly mechanisms was recognized in the late nineties [BW96, HO99, CLC05]).

Some practice-oriented studies have been devoted to analyze different issues when one is faced with the adaptation of a third-party component [GAO99]. A formal foundation to the notion of interoperability and component adaptation was set up in [YS97]. Component behavior specifications are given by finite state machines which are well known and support simple and efficient verification techniques for the protocol compatibility. Braccalia & al [BBC05] specify an adapter as a set of correspondences between methods and parameters of the required and provided components. An adapter is formalized as a set of properties expressed in  $\pi$ -calculus. From this specification and from both interfaces, they generate a concrete implementable adapter.

Reussner and Schmit consider a certain class of protocol interoperability problems in the context of concurrent systems. For bridging component protocol incompatibilities, they generate adapters using interfaces described by finite state machines [SR02, RSP03].

Automatic generation of adapters are limited as one has to ensure the decidability of the interfaces inclusion problem, which is necessary to perform automated interoperability checks; one could only generate adapters for specific classes of assembly.

In our approach, we are not only concerned with specific classes of interoperability but with adapters in general. We propose to give general schemes to specify and verify adapters, not to generate them automatically.

## 7 Conclusion and Perspectives

We have presented a component-based approach to specify systems with high safety requirements. This approach concerns the first steps of the system development life-cycle, from the requirements phase to the specification one, and aims at using existing languages and tools. Components are considered as black-boxes described by their visible behavior and their required and provided interfaces. To construct a working system out of existing components, adapters are introduced. An adapter is a new component that expresses the mapping between required and provided variables and how required methods are implemented in terms of the provided ones. We have presented a general schema of assembly with both cases of interfaces.

The use of the B formal method and its refinement mechanisms to model the component interfaces and the adapters allows us to define rigorously the interoperability between components and to check it with support tools. The B prover guarantees that the adapter is a correct implementation of the required functionalities in terms of the existing components. Within this approach, the verification of the interoperability between the connected components is done at three levels, the signature, the semantic and the protocol levels.

We are currently working on extending this approach when additional abnormal behaviors are introduced to increase dependability of our component architecture and to preserve the normal cases. We have introduced two kinds of dependability mechanisms, one for security and one for safety.
