HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract. Starting from an arbitrary cluster-tilting object $T$ in a 2-Calabi–Yau category over an algebraically closed field, as in the setting of Keller and Reiten, we define, for each object $L$, a fraction $X(T, L)$ using a formula proposed by Caldero and Keller. We show that the map taking $L$ to $X(T, L)$ is a cluster character, i.e. that it satisfies a certain multiplication formula. We deduce that it induces a bijection, in the finite and the acyclic case, between the indecomposable rigid objects of the cluster category and the cluster variables, which confirms a conjecture of Caldero and Keller.

Introduction

Cluster algebras were invented and studied by S. Fomin and A. Zelevinsky in \cite{Fomin1}, \cite{Fomin2}, \cite{Fomin3} and in collaboration with A. Berenstein in \cite{Berenstein}. They are commutative algebras endowed with a distinguished set of generators called the cluster variables. These generators are gathered into overlapping sets of fixed finite cardinality, called clusters, which are defined recursively from an initial one via an operation called mutation. A cluster algebra is said to be of finite type if it only has a finite number of cluster variables. The finite type cluster algebras were classified in \cite{Fomin3}.

It was recognized in \cite{Buan} that the combinatorics of cluster mutation are closely related to those of tilting theory in the representation theory of quivers and finite dimensional algebras. This discovery was the main motivation for the invention of cluster categories (in \cite{Caldero} for the $A_n$-case and in \cite{Buan} for the general case). These are certain triangulated categories \cite{Keller} which, in many cases, allow one to ‘categorify’ cluster algebras: In the categorical setting, the cluster-tilting objects play the role of the clusters, and their indecomposable direct summands the one of the cluster variables.

In \cite{Buan}, \cite{Buan2}, \cite{Buan3}, the authors study another setting for the categorification of cluster algebras: The module categories of preprojective algebras of Dynkin type. They succeed in categorifying a different class of cluster algebras, which also contains many cluster algebras of infinite type.

Both cluster categories and module categories of preprojective algebras of Dynkin type are 2-Calabi–Yau categories in the sense that we have bifunctorial isomorphisms

$$\text{Ext}^1(X, Y) \simeq D \text{Ext}^1(Y, X),$$

which are highly relevant in establishing the link with cluster algebras. This motivates the study of more general 2-Calabi–Yau categories in \cite{Buan4}, \cite{Buan5}, \cite{Buan6}, \cite{Buan7}, \cite{Buan8}. In order to show that a given 2-Calabi–Yau category ‘categorifies’ a given cluster algebra, a crucial point is

a) to construct an explicit map from the set of indecomposable factors of cluster-tilting objects to the set of cluster variables, and

b) to show that it is bijective.

Such a map was constructed for module categories of preprojective algebras of Dynkin type in \cite{Buan4} using Lusztig’s work \cite{Lusztig}. For cluster categories, it was defined...
by P. Caldero and F. Chapoton in [8]. More generally, for each object \( M \) of the cluster category, they defined a fraction \( X_M \) in \( \mathbb{Q}(x_1, \ldots, x_n) \). The bijectivity property of the Caldero–Chapoton map was proved in [8] for finite type and in [10], cf. also [3], for acyclic type.

A crucial property of the Caldero–Chapoton map is the following. For any pair of indecomposable objects \( L \) and \( M \) of \( C \) whose extension space \( C(L, \Sigma M) \) is one-dimensional, we have

\[
X_L X_M = X_B + X_B',
\]

where \( \Sigma \) denotes the suspension in \( C \) and where \( B \) and \( B' \) are the middle terms of ‘the’ two non-split triangles with outer terms \( L \) and \( M \). We define, in definition 1.2, a cluster character to be a map satisfying this multiplication formula.

This property has been proved in [9] in the finite case, in [15] for the analogue of the Caldero–Chapoton map in the preprojective case, and in [10] in the acyclic case.

The main result of this article is a generalisation of this multiplication formula. Starting from an arbitrary cluster-tilting object \( T \) and an arbitrary 2-Calabi–Yau category \( C \) over an algebraically closed field (as in the setting of [23]), we define, for each object \( L \) of \( C \), a fraction \( X_T^L \) using a formula proposed in [9, 6.1]. We show that the map \( L \mapsto X_T^L \) is a cluster character. We deduce that it has the bijectivity property in the finite and the acyclic case, which confirms conjecture 2 of [9]. Here, it yields a new way of expressing cluster variables as Laurent polynomials in the variables of a fixed cluster. Our theorem also applies to stable categories of preprojective algebras of Dynkin type and their Calabi–Yau reductions studied in [14] and [3].

Let \( k \) be an algebraically closed field, and let \( C \) be a 2-Calabi–Yau Hom-finite triangulated \( k \)-category with a cluster-tilting object \( T \) (see section 1). The article is organised as follows: In the first section, the notations are given and the main result is stated. In the next two sections, we investigate the exponents appearing in the definition of \( X_T^L \). In section 2, we define the index and the coindex of an object of \( C \) and show how they are related to the exponents. Section 3 is devoted to the study of the antisymmetric bilinear form \( \langle \cdot, \cdot \rangle^a \) on \( \text{mod} \ \text{End}_C T \). We show that this form descends to the Grothendieck group \( K_0(\text{mod} \ \text{End}_C T) \), confirming conjecture 1 of [9, 6.1]. In section 4, we prove that the same phenomenon of dichotomy as in [10, section 3] (see also [15]) still holds in our setting. The results of the first sections are used in section 5 to prove the multiplication formula. We draw some consequences in section 5.2. Two examples are given in section 6.

Acknowledgements

This article is part of my PhD thesis, under the supervision of Professor B. Keller. I would like to thank him deeply for introducing me to the subject. I would also like to thank P. Caldero for his comments, and J. Schröer for suggesting lemma 5.3 to me.

1. Main result
2. Index, coindex and Euler form
2.1. Index and coindex
1. Main result

Let \( k \) be an algebraically closed field, and let \( \mathcal{C} \) be a \( k \)-linear triangulated category with split idempotents. Denote by \( \Sigma \) its suspension functor. Assume moreover that the category \( \mathcal{C} \)

a) is Hom-finite: For any two objects \( X \) and \( Y \) in \( \mathcal{C} \), the space of morphisms \( \mathcal{C}(X, Y) \) is finite-dimensional,

b) is 2-Calabi–Yau: There exist bifunctorial isomorphisms
\[
\mathcal{C}(X, \Sigma Y) \simeq D \mathcal{C}(Y, \Sigma X),
\]
where \( D \) denotes the duality functor \( \text{Hom}_k(?, k) \), and

c) admits a cluster-tilting object \( T \), which means that
i) \( \mathcal{C}(T, \Sigma T) = 0 \) and

ii) for any \( X \) in \( \mathcal{C} \), if \( \mathcal{C}(X, \Sigma T) = 0 \), then \( X \) belongs to the full subcategory \( \text{add} T \) formed by the direct summands of sums of copies of \( T \).

For two objects \( X \) and \( Y \) of \( \mathcal{C} \), we often write \( (X, Y) \) for the space of morphisms \( \mathcal{C}(X, Y) \) and we denote its dimension by \( [X, Y] \). Similarly, we write \( 1(X, Y) \) for \( \mathcal{C}(X, \Sigma Y) \) and \( 1[X, Y] \) for its dimension. Let \( B \) be the endomorphism algebra of \( T \) in \( \mathcal{C} \), and let \( \text{mod} B \) be the category of finite-dimensional right \( B \)-modules. As shown in \[23\], cf. also \[24\], the functor
\[
F : \mathcal{C} \rightarrow \text{mod} B, \quad X \mapsto \mathcal{C}(T, X),
\]
induces an equivalence of categories
\[
\mathcal{C}/(\Sigma T) \xrightarrow{\sim} \text{mod} B,
\]
where \( (\Sigma T) \) denotes the ideal of morphisms of \( \mathcal{C} \) which factor through a direct sum of copies of \( \Sigma T \).

The following useful proposition is proved in \[23\] and \[24\]:

**Proposition 1.1.** Let \( X \xrightarrow{f} Y \xrightarrow{g} Z \rightarrow \Sigma X \) be a triangle in \( \mathcal{C} \). Then

- The morphism \( g \) induces a monomorphism in \( \text{mod} B \) if and only if \( f \in (\Sigma T) \).
- The morphism \( f \) induces an epimorphism in \( \text{mod} B \) if and only if \( g \in (\Sigma T) \).

Moreover, if \( X \) has no direct summands in \( \text{add} \Sigma T \), then \( FX \) is projective (resp. injective) if and only if \( X \) lies in \( \text{add} (T) \) (resp. in \( \text{add} (\Sigma^2 T) \)).
Definition 1.2. A cluster character on $\mathcal{C}$ with values in a commutative ring $A$ is a map

$$\chi : \text{obj}(\mathcal{C}) \to A$$

such that

1. for all isomorphic objects $L$ and $M$, we have $\chi(L) = \chi(M)$,
2. for all objects $L$ and $M$ of $\mathcal{C}$, we have $\chi(L \oplus M) = \chi(L) \chi(M)$,
3. for all objects $L$ and $M$ of $\mathcal{C}$ such that $\dim \text{Ext}^1_{\mathcal{C}}(L, M) = 1$, we have

$$\chi(L) \chi(M) = \chi(B) + \chi(B'),$$

where $B$ and $B'$ are the middle terms of ‘the’ non-split triangles

$$L \to B \to M \to \Sigma L$$

and

$$M \to B' \to L \to \Sigma M$$

with end terms $L$ and $M$.

Let $N$ be a finite-dimensional $B$-module and $e$ an element of $K_0(\text{mod } B)$. We write $\text{Gr}_e(N)$ for the variety of submodules $N'$ of $N$ whose class in $K_0(\text{mod } B)$ is $e$. It is a closed, hence projective, subvariety of the classical Grassmannian of subspaces of $N$. Let $\chi(\text{Gr}_e(N))$ denote its Euler–Poincaré characteristic with respect to the étale cohomology with proper support. Let $K^\text{sp}_0(\text{mod } B)$ denote the ‘split’ Grothendieck group of mod $B$, i.e. the quotient of the free abelian group on the set of isomorphism classes $[N]$ of finite-dimensional $B$-modules $N$, modulo the subgroup generated by all elements

$$[N_1 \oplus N_2] - [N_1] - [N_2].$$

We define a bilinear form

$$\langle , \rangle : K^\text{sp}_0(\text{mod } B) \times K^\text{sp}_0(\text{mod } B) \to \mathbb{Z}$$

by setting

$$\langle N, N' \rangle = [N, N'] - 1[N, N']$$

for all finite-dimensional $B$-modules $N$ and $N'$. We define an antisymmetric bilinear form on $K^\text{sp}_0(\text{mod } B)$ by setting

$$\langle N, N' \rangle_a = \langle N, N' \rangle - \langle N', N \rangle$$

for all finite-dimensional $B$-modules $N$ and $N'$. Let $T_1, \ldots, T_n$ be the pairwise non-isomorphic indecomposable direct summands of $T$ and, for $i = 1, \ldots, n$, let $S_i$ be the top of the projective $B$-module $P_i = FT_i$. The set $\{S_i, i = 1, \ldots, n\}$ is a set of representatives for the isoclasses of simple $B$-modules.

We need a lemma, the proof of which will be given in section 3.1.

Lemma 1.3. For any $i = 1, \ldots, n$, the linear form $\langle S_i, ? \rangle_a : K^\text{sp}_0(\text{mod } B) \to \mathbb{Z}$ induces a well-defined form

$$\langle S_i, ? \rangle_a : K_0(\text{mod } B) \to \mathbb{Z}.$$

Let $\text{ind } \mathcal{C}$ be a set of representatives for the isoclasses of indecomposable objects of $\mathcal{C}$. Define, as in [6, 6.1], a Caldero–Chapoton map, $X_T^\mathcal{C} : \text{ind } \mathcal{C} \to \mathbb{Q}(x_1, \ldots, x_n)$ by

$$X_T^\mathcal{C}_M = \left\{ x_i \text{ if } M \cong \Sigma T_i \sum_{e \in \mathcal{C}} \chi(\text{Gr}_e FM) \prod_{i=1}^n x_i^{\langle S_i, e \rangle_a - \langle S_i, FM \rangle} \right\}$$

else.

Extend it to a map $X_T^\mathcal{C} : \mathcal{C} \to \mathbb{Q}(x_1, \ldots, x_n)$ by requiring that $X_T^\mathcal{C}_{M \oplus N} = X_T^\mathcal{C}_M X_T^\mathcal{C}_N$. When there are no possible confusions, we often denote $X_T^\mathcal{C}_M$ by $X_M$. The main result of this article is the following

Theorem 1.4. The map $X_T^\mathcal{C} : \mathcal{C} \to \mathbb{Q}(x_1, \ldots, x_n)$ is a cluster character.

We will prove the theorem in section 5.1, illustrate it by examples in section 5.2, and draw some consequences in section 5.3.
2. INDEX, COINDEX AND EULER FORM

In the next two sections, our aim is to understand the exponents appearing in the definition of $X_B$. More precisely, for two objects $L$ and $M$ of $C$, we want to know how the exponents in $X_B$ depend on the choice of the middle term $B$ of a triangle with outer terms $L$ and $M$.

2.1. Index and coindex. Let $X$ be an object of $C$. Define its index $\text{ind} X \in K_0(\text{proj } B)$ as follows. There exists a triangle (see [KR1])

$$T_1^X \rightarrow T_0^X \rightarrow X \rightarrow \Sigma T_1^X$$

with $T_0^X$ and $T_1^X$ in $\text{add } T$. Define $\text{ind} X$ to be the class $\left[ FT_0^X \right] - \left[ FT_1^X \right]$ in $K_0(\text{proj } B)$. Similarly, define the coindex of $X$, denoted by $\text{coind} X$, to be the class $\left[ FT_1^X \right] - \left[ FT_0^X \right]$ in $K_0(\text{proj } B)$, where

$$X \rightarrow \Sigma^2 T_0^X \rightarrow \Sigma^2 T_1^X \rightarrow \Sigma X$$

is a triangle in $C$ with $T_0^X, T_1^X \in \text{add } T$.

Lemma 2.1. We have the following properties:

1. The index and coindex are well defined.
2. $\text{ind} X = - \text{coind} \Sigma X$.
3. $\text{ind} T_i = \left[ P_i \right]$ and $\text{ind} \Sigma T_i = -\left[ P_i \right]$ where $P_i = FT_i$.
4. $\text{ind} X - \text{coind} X$ only depends on $FX \in \text{mod } B$.

Proof. A right $\text{add } T$-approximation of an object $X$ of $C$ is a morphism $T' \xrightarrow{f} X$ with $T' \in \text{add } T$ such that any morphism $T'' \rightarrow X$ with $T'' \in \text{add } T$ factors through $f$. It is called minimal if, moreover, any morphism $T' \xrightarrow{g} T'$ such that $fg = f$ is an isomorphism. A minimal approximation is unique up to isomorphism. Assertions (2) and (3) are left to the reader.

(1) In any triangle of the form

$$T_1^X \rightarrow T_0^X \xrightarrow{f} X \rightarrow \Sigma T_1^X,$$

the morphism $f$ is a right $\text{add } T$-approximation. Therefore, any such triangle is obtained from one where $f$ is minimal by adding a trivial triangle

$$T' \rightarrow T' \rightarrow 0 \rightarrow \Sigma T'$$

with $T' \in \text{add } T$. The index is thus well-defined. Dually, one can define left approximations and show that the coindex is well-defined.

(4) Let $T'$ be an object in $\text{add } T$. Take two triangles

$$T_1^X \rightarrow T_0^X \rightarrow X \rightarrow \Sigma T_1^X$$

and

$$X \rightarrow \Sigma^2 T_0^X \rightarrow \Sigma^2 T_1^X \rightarrow \Sigma X$$

with $T_0^X, T_1^X, T_0^X$ and $T_1^X$ in $\text{add } T$. Then, we have two triangles

$$T_1^Y \oplus T' \rightarrow T_0^X \rightarrow X \oplus \Sigma T' \rightarrow \Sigma (T_1^Y \oplus T')$$

and

$$X \oplus \Sigma T' \rightarrow \Sigma^2 T_0^X \rightarrow \Sigma^2 (T_1^X \oplus T') \rightarrow \Sigma X \oplus \Sigma^2 T'.$$

We thus have the equality:

$$\text{ind}(X \oplus \Sigma T') - \text{coind}(X \oplus \Sigma T') = \text{ind} X - \text{coind} X.$$

□
**Proposition 2.2.** Let $X \xrightarrow{f} Z \xrightarrow{g} Y \xrightarrow{\varepsilon} \Sigma X$ be a triangle in $C$. Take $C \in C$ (resp. $K \in C$) to be any lift of $\text{Coker } Fg$ (resp. $\text{Ker } Ff$). Then

\[
\text{ind } Z = \text{ind } X + \text{ind } Y - \text{ind } C - \text{ind } \Sigma^{-1} C \quad \text{and} \quad \text{coind } Z = \text{coind } X + \text{coind } Y - \text{coind } K - \text{coind } \Sigma K.
\]

**Proof.** Let us begin with the equality for the indices. First, consider the case where $FC = 0$. This means that the morphism $\varepsilon$ belongs to the ideal $(\Sigma T)$. Take two triangles $T^X_1 \rightarrow T^X_0 \rightarrow X \rightarrow \Sigma T^X_1$ and $T^Y_1 \rightarrow T^Y_0 \rightarrow Y \rightarrow \Sigma T^Y_1$ in $C$, where the objects $T^X_0, T^X_1, T^Y_0, T^Y_1$ belong to the subcategory $\text{add } T$. Since the morphism $\varepsilon$ belongs to the ideal $(\Sigma T)$, the composition $T^Y_0 \rightarrow Y \xrightarrow{\varepsilon} \Sigma X$ vanishes. The morphism $T^Y_0 \rightarrow Y$ thus factors through $g$. This gives a commutative square

\[
\begin{array}{c}
T^X_0 \oplus T^Y_0 \rightarrow T^Y_0 \\
\downarrow \quad \downarrow \\
Z \rightarrow Y
\end{array}
\]

Fit it into a nine-diagram

\[
\begin{array}{c}
T^X \rightarrow Z' \rightarrow T^Y \rightarrow \Sigma T^X \\
\downarrow \quad \downarrow \quad \downarrow \\
T^X_0 \oplus T^Y_0 \rightarrow T^Y_0 \rightarrow \Sigma T^X_1 \\
\downarrow \quad \downarrow \\
X \rightarrow Z \rightarrow Y \\
\downarrow \quad \downarrow \quad \downarrow \\
\Sigma T^X_1 \rightarrow \Sigma Z' \rightarrow \Sigma T^Y_1,
\end{array}
\]

whose rows and columns are triangles. Since the morphism $T^Y_1 \rightarrow \Sigma T^X_1$ vanishes, the triangle in the first row splits, so that we have $Z' \simeq T^X_1 + T^Y_1$ and $\text{ind } Z = \text{ind } X + \text{ind } Y$.

Now, let us prove the formula in the general case. Let $FY \xrightarrow{a} M$ be a cokernel for $Fg$. Since the composition $F\varepsilon Fg$ vanishes, the morphism $F\varepsilon$ factors through $a$:

\[
\begin{array}{c}
FY \quad \xrightarrow{F\varepsilon} \\
\downarrow \quad \downarrow \\
M \quad \quad \Sigma X.
\end{array}
\]

Let $Y \xrightarrow{\alpha} C'$ be a lift of $a$ in $C$, and let $\beta$ be a lift of $b$. The images under $F$ of the morphisms $\varepsilon$ and $\beta \alpha$ coincide, therefore the morphism $\beta \alpha - \varepsilon$ belongs to the ideal $(\Sigma T)$. Thus there exist an object $T'$ in $\text{add } T$ and two morphisms $\alpha'$ and $\beta'$ such that the following diagram commutes:

\[
\begin{array}{c}
Y \quad \xrightarrow{\varepsilon} \\
\downarrow \quad \downarrow \\
\Sigma X.
\end{array}
\]

\[
\begin{array}{c}
C' \oplus \Sigma T' \\
\downarrow \quad \downarrow \\
[\alpha'] \quad [\beta']
\end{array}
\]

Let $C$ be the direct sum $C' \oplus \Sigma T'$. 
The octahedral axiom yields a commutative diagram

\[
\begin{array}{c}
\text{U} \\
X \\
X
\end{array}
\quad \begin{array}{c}
\text{U} \\
Z \\
V
\end{array}
\quad \begin{array}{c}
\Sigma X \\
\Sigma X \\
\Sigma X
\end{array}
\quad \begin{array}{c}
\varepsilon \\
\gamma' \\
\gamma'
\end{array}
\quad \begin{array}{c}
\Sigma X \\
C \\
\Sigma X
\end{array}
\quad \begin{array}{c}
\Sigma X \\
\Sigma X \\
\Sigma X
\end{array}
\quad \begin{array}{c}
\Sigma U \\
\Sigma U \\
\Sigma U
\end{array}
\]

whose two central rows and columns are triangles. Due to the choice of $C$, the morphisms $\gamma', \gamma''$, hence $\gamma$ belong to the ideal $(\Sigma T)$. We thus have the equalities:

\[
\begin{align*}
\text{ind } Y &= \text{ind } C + \text{ind } U, \\
\text{ind } X &= \text{ind } V + \text{ind } \Sigma^{-1} C, \\
\text{ind } Z &= \text{ind } V + \text{ind } U,
\end{align*}
\]

giving the desired formula. Moreover, as seen in lemma 2.1 (4), the sum $\text{ind } C + \text{ind } \Sigma^{-1} C = \text{ind } C - \text{coind } C$ does not depend on the particular choice of $C$. Apply this formula to the triangle

\[
\Sigma^{-1} X \rightarrow \Sigma^{-1} Z \rightarrow \Sigma^{-1} Y \rightarrow X
\]

and use lemma 2.1(2) to obtain the formula for the coindices. Remark that the long exact sequence yields the equality of $\text{Coker}(-F \Sigma^{-1} g)$ and $\text{Ker } f$.

2.2. Exponents. We now compute the index and coindex in terms of the Euler form.

**Lemma 2.3.** Let $X \in \mathcal{C}$ be indecomposable. Then

\[
\text{ind } X = \begin{cases} 
-[P_i] & \text{if } X \simeq \Sigma T_i \\
\sum_{i=1}^n \langle F_X, S_i \rangle [P_i] & \text{else}, 
\end{cases}
\]

\[
\text{coind } X = \begin{cases} 
-[P_i] & \text{if } X \simeq \Sigma T_i \\
\sum_{i=1}^n \langle S_i, F_X \rangle [P_i] & \text{else}. 
\end{cases}
\]

**Proof.** Let $X$ be an indecomposable object in $\mathcal{C}$, non-isomorphic to any of the $\Sigma T_i$’s. Take a triangle

\[
T_i^X \xrightarrow{f} T_0^X \xrightarrow{g} X \xrightarrow{\varepsilon} \Sigma T_i^X
\]

with the morphism $g$ being a minimal right add $T$-approximation, as defined in the proof of lemma 2.1. We thus get a minimal projective presentation

\[
P_i^X \rightarrow P_0^X \rightarrow F_X \rightarrow 0
\]

where $P_i^X = FT_i^X, i = 0, 1$. For any $i$, the differential in the complex

\[
0 \rightarrow (P_0^X, S_i) \rightarrow (P_1^X, S_i) \rightarrow \cdots
\]

vanishes. Therefore, we have

\[
\begin{align*}
[F_X, S_i] &= [P_0^X : S_i] = [P_0^X : P_i], \\
1[F_X, S_i] &= [P_1^X, S_i] = [P_1^X : P_i], \\
\langle F_X, S_i \rangle &= [\text{ind } X : P_i].
\end{align*}
\]
The proof for the coindex is analogous: We use a minimal injective copresentation of $F X$ induced by a triangle

$$X \to \Sigma^2 T^0_X \to \Sigma^2 T^1_X \to \Sigma X.$$  

\[\square\]

Let us write $x^e$ for $\prod_{i=1}^n x_i^{[e : P_i]}$ where $e \in K_0(\text{proj } B)$ and $[e : P_i]$ is the $i$th coefficient of $e$ in the basis $[P_1], \ldots, [P_n]$. Then, by lemma 2.3, for any indecomposable object $M$ in $\mathcal{C}$, we have

$$X_M = \mathbb{L}^{-\text{coind } M} \sum_e \chi(\text{Gr}_e FM) \prod_{i=1}^n x_i^{S_i, e}.$$  

3. The antisymmetric bilinear form

In this part, we give a positive answer to the first conjecture of [6, 6.1] and prove that the exponents in $X_M$ are well defined. The first lemma is sufficient for this latter purpose, but is not very enlightening, whereas the second proof of theorem 3.4 gives us a better understanding of the antisymmetric bilinear form. When the category $\mathcal{C}$ is algebraic, this form is, in fact, the usual Euler form on the Grothendieck group of a triangulated category together with a t-structure whose heart is the abelian category $\text{mod } B$ itself.

3.1. The map $X^T$ is well defined. Let us first show that any short exact sequence in $\text{mod } B$ can be lifted to a triangle in $\mathcal{C}$.

**Lemma 3.1.** Let $0 \to x \to y \to z \to 0$ be a short exact sequence in $\text{mod } B$. Then there exists a triangle in $\mathcal{C}$

$$X \to Y \to Z \to \Sigma X$$

whose image under $F$ is isomorphic to the given short exact sequence.

**Proof.** Let

$$0 \to x \xrightarrow{i} y \xrightarrow{p} z \to 0$$

be a short exact sequence in $\text{mod } B$. Let $X \xrightarrow{f} Y$ be a lift of the monomorphism $x \xrightarrow{i} y$ in $\mathcal{C}$. Fix a triangle

$$T^X_1 \to T^X_0 \to X \to \Sigma T^X_1$$

and form a triangle

$$X \to Y \oplus \Sigma T^X_1 \to Z \xrightarrow{\varepsilon} \Sigma X.$$  

The commutative left square extends to a morphism of triangles

\[
\begin{array}{ccc}
X & \xrightarrow{i} & Y \oplus \Sigma T^X_1 \\
\downarrow & & \downarrow \\
X & \xrightarrow{f} & \Sigma T^X_1
\end{array}
\]

so that the morphism $\varepsilon$ lies in the ideal $(\Sigma T)$. Therefore, the sequence

$$0 \to x \xrightarrow{i} y \to FZ \to 0$$

is exact, and the modules $FZ$ and $z$ are isomorphic. \[\square\]
Proof of lemma 1.3.

Let $X$ be an object of the category $C$. Using section 2.2 we have

$$\text{coind } X - \text{ ind } X = \sum_{i=1}^{n} \langle S_i, F X \rangle_a [P_i].$$

Therefore, it is sufficient to show that the form

$$K_0(\text{mod } B) \longrightarrow \mathbb{Z} [F X] \longrightarrow \text{coind } X - \text{ ind } X$$

is well defined. We already know that coind $X - \text{ ind } X$ only depends on $F X$. Take $0 \to x \to y \to z \to 0$ to be a short exact sequence in mod $B$. Lift it, as in lemma 3.1, to a triangle

$$X \longrightarrow Y \longrightarrow Z \longrightarrow \Sigma X \text{ in } C.$$

By proposition 2.2, we have

$$\text{ind } Y - \text{coind } Y = (\text{ind } X + \text{ ind } Z) - (\text{coind } X + \text{coind } Z)$$

which is the required equality. $\square$

Corollary 3.2. The map

$$X^T : C \longrightarrow \mathbb{Q}(x_1, \ldots, x_n)$$

is well defined.

3.2. The antisymmetric bilinear form descends to the Grothendieck group.

In this subsection, we prove a stronger result than in the previous one. This gives a positive answer to the first conjecture in [9, 6.1].

Lemma 3.3. Let $T'$ be any cluster-tilting object in $C$. We have bifunctorial isomorphisms

$$C / (T') (\Sigma^{-1} X, Y) \simeq D(T') (\Sigma^{-1} Y, X).$$

Proof. Let $X$ and $Y$ be two objects of $C$, and let $T'_1 \longrightarrow T'_0 \longrightarrow X \longrightarrow \Sigma T'_1$ be a triangle in $C$, with $T'_0$ and $T'_1$ in add $T'$. Consider the morphism

$$\alpha : (T'_1, Y) \longrightarrow (\Sigma^{-1} X, Y), \quad f \mapsto f \circ \Sigma^{-1} \eta.$$

We have

$$D(T')(\Sigma^{-1} X, Y) \simeq D \text{ Im } \alpha \simeq \text{ Im } D\alpha.$$

Since the category $C$ is 2-Calabi–Yau, the dual of $\alpha$, $D\alpha$, is isomorphic to

$$\alpha' : (\Sigma^{-1} Y, X) \longrightarrow (\Sigma^{-1} Y, \Sigma T'_1), \quad g \mapsto \eta \circ g.$$

We thus have isomorphisms

$$D(T')(\Sigma^{-1} X, Y) \simeq \text{ Im } \alpha' \simeq (\Sigma^{-1} Y, X) / \text{ Ker } \alpha' \simeq C / (T') (\Sigma^{-1} Y, X).$$

$\square$

Theorem 3.4. The antisymmetric bilinear form $(\ , \ )_\alpha$ descends to the Grothendieck group $K_0(\text{mod } B)$. 

Proof. Let $X$ and $Y$ be two objects in the category $C$. In order to compute $\langle FX, FY \rangle = [FX, FY] - 1[FX, FY]$, let us construct a projective presentation in the following way. Let

$$
\Sigma^{-1}X \overset{g}{\longrightarrow} T_1^X \overset{f}{\longrightarrow} T_0^X \longrightarrow X
$$

be a triangle in $C$ with $T_0^X$ and $T_1^X$ being two objects in the subcategory $\text{add} \, T$. This triangle induces an exact sequence in $\text{mod} \, B$

$$
F\Sigma^{-1}X \overset{Fg}{\longrightarrow} FT_1^X \overset{Ff}{\longrightarrow} FT_0^X \longrightarrow FX \longrightarrow 0,
$$

where $FT_0^X$ and $FT_1^X$ are finite-dimensional projective $B$-modules. Form the complex

$$(*) \quad 0 \longrightarrow \text{Hom}_B(FT_0^X, FY) \longrightarrow \text{Hom}_B(FT_1^X, FY) \longrightarrow \text{Hom}_B(F\Sigma^{-1}X, FY).$$

Since the object $T$ is cluster-tilting in $C$, there are no morphisms from any object in $\text{add} \, T$ to any object in $\text{add} \, \Sigma T$. The complex $(*)$ is thus isomorphic to the following one:

$$
0 \longrightarrow \mathcal{C}(T_0^X, Y) \overset{f^*}{\longrightarrow} \mathcal{C}(T_1^X, Y) \overset{g^*}{\longrightarrow} \mathcal{C}(\Sigma^{-1}X, Y),
$$

where $f^*$ (resp. $g^*$) denotes the composition by $f$ (resp. $g$). Therefore, we have

$$
\text{Hom}_B(FX, FY) \simeq \ker f^*, \quad \text{Ext}_B^{1}(FX, FY) \simeq \ker g^*/\ker f^*.
$$

We can now express the bilinear form as

$$
\langle FX, FY \rangle = \dim \ker f^* - \dim \ker g^* + \text{rk} \, f^*
$$

$$
= [T_1^X, Y] - [T_0^X, Y] + \text{rk} \, g^*,
$$

with the image of the morphism $g^*$ being the quotient by the ideal $(\Sigma T)$ of the space of morphisms from $\Sigma^{-1}X$ to $Y$, in $C$, which belong to the ideal ($T$):

$$
\text{Im} \, g^* = (T)/(\Sigma T)(\Sigma^{-1}X, Y).
$$

Similarly, using an injective copresentation given by a triangle of the form

$$
X \longrightarrow \Sigma^2 T_0^X \longrightarrow \Sigma^2 T_1^X \overset{\beta}{\longrightarrow} \Sigma X,
$$

we obtain

$$
\langle FY, FX \rangle = [Y, \Sigma^2 T_0^X] - [Y, \Sigma^2 T_1^X] + \text{rk} \, \beta^*,
$$

and $\text{Im} \, \beta^* = (\Sigma^2 T)/(\Sigma T)(Y, \Sigma X)$. By lemma 3.3, we have bifunctorial isomorphisms

$$
(T)/(\Sigma T)(\Sigma^{-1}X, Y) \simeq D(\Sigma T)/(\Sigma T)(\Sigma^{-1}Y, X) \simeq D(\Sigma^2 T)/(\Sigma T)(Y, \Sigma X).
$$

Therefore, we have the equality

$$
\langle FX, FY \rangle_a = [T_0^X, Y] - [T_1^X, Y] - [Y, \Sigma^2 T_0^X] + [Y, \Sigma^2 T_1^X]
$$

$$
= [FT_0^X, FY] - [FT_1^X, FY] - [FY, F\Sigma^2 T_0^X] + [FY, F\Sigma^2 T_1^X].
$$

Since $FT$ is projective and $F\Sigma^2 T$ is injective, this formula shows that $\langle , \rangle_a$ descends to a bilinear form on the Grothendieck group $K_0(\text{mod} \, B)$. □
3.3. The antisymmetric bilinear form and the Euler form. In this subsection, assume moreover that the category \( \mathcal{C} \) is algebraic, as in [23, section 4]: There exists a \( k \)-linear Frobenius category with split idempotents \( \mathcal{E} \) whose stable category is \( \mathcal{C} \). Denote by \( \mathcal{M} \) the preimage, in \( \mathcal{E} \), of \( \text{add} \, T \) via the canonical projection functor. The category \( \mathcal{M} \) thus contains the full subcategory \( \mathcal{P} \) of \( \mathcal{E} \) whose objects are the projective objects in \( \mathcal{E} \), and we have \( \mathcal{M} = \text{add} \, T \). Let \( \text{Mod} \mathcal{M} \) be the category of \( \mathcal{M} \)-modules, i.e. of \( k \)-linear contravariant functors from \( \mathcal{M} \) to the category of \( k \)-vector spaces. The category \( \text{mod} \mathcal{M} \) of finitely presented \( \mathcal{M} \)-modules is identified with the full subcategory of \( \text{Mod} \mathcal{M} \) of finitely presented \( \mathcal{M} \)-modules vanishing on \( \mathcal{P} \). This last category is equivalent to the abelian category \( \text{mod} \, B \) of finitely generated \( B \)-modules. Recall that the perfect derived category \( \text{per} \mathcal{M} \) is the full triangulated subcategory of the derived category of \( D \text{Mod} \mathcal{M} \) generated by the finitely generated projective \( \mathcal{M} \)-modules. Define \( \text{per} \mathcal{M} \) to be the full subcategory of \( \text{per} \mathcal{M} \) whose objects \( X \) satisfy the following conditions:

1. for each integer \( n \), the finitely presented \( \mathcal{M} \)-module \( H^n \mathcal{M} \) belongs to \( \text{mod} \mathcal{M} \).
2. the module \( H^n \mathcal{M} \) vanishes for all but finitely many \( n \in \mathbb{Z} \).

It can easily be shown that \( \text{per} \mathcal{M} \) is a triangulated subcategory of \( \text{per} \mathcal{M} \). Moreover, as shown in [23], the canonical t-structure on \( D \text{Mod} \mathcal{M} \) induces a t-structure on \( \text{per} \mathcal{M} \), whose heart is the abelian category \( \text{mod} \mathcal{M} \).

The following lemma shows that the Euler form

\[
\kappa_0(\text{per} \mathcal{M}) \times \kappa_0(\text{per} \mathcal{M}) \rightarrow \mathbb{Z}
\]

\[
([X],[Y]) \mapsto \langle [X],[Y] \rangle = \sum_{i \in \mathbb{Z}} (-1)^i \dim \text{per} \mathcal{M}(X, \Sigma^i Y)
\]

is well defined.

**Lemma 3.5.** Let \( X \) and \( Y \) belong to \( \text{per} \mathcal{M} \). Then the vector spaces \( \text{per} \mathcal{M}(X, \Sigma^i Y) \) are finite dimensional and only finitely many of them are non-zero.

**Proof.** Since \( X \) belongs to \( \text{per} \mathcal{M} \), we may assume that it is representable: There exists \( M \) in \( \mathcal{M} \) such that \( X = \mathcal{M} \). Moreover, the module \( H^n \mathcal{M} \) vanishes for all but finitely many \( n \in \mathbb{Z} \). We thus may assume \( Y \) to be concentrated in degree 0. Therefore, the space \( \text{per} \mathcal{M}(X, \Sigma^i Y) = \text{per} \mathcal{M}(M, \Sigma^i H^n \mathcal{M} \mathcal{M}(?) \mathcal{M}(M, \Sigma^i H^n Y) \) vanishes for all non-zero \( i \). For \( i = 0 \), it equals

\[
\text{Hom}_\mathcal{M}(M, H^0 \mathcal{M}) = H^0 \mathcal{M}(M) = \text{Hom}_\mathcal{M}(\mathcal{M}(?), \mathcal{M}(H^0 Y)).
\]

this last space being finite dimensional.

\[\square\]

This enables us to give another proof of theorem 3.4. This proof is less general than the previous one, but is nevertheless much more enlightening.
Proof of theorem 3.4. Let $X$ and $Y$ be two finitely presented $\mathcal{M}$-modules, lying in the heart of the t-structure on $\text{per}_{\mathcal{M}}$. We have:

$$\langle [X], [Y] \rangle = \sum_{i \in \mathbb{Z}} (-1)^i \dim \text{per}_{\mathcal{M}} \mathcal{M}(X, \Sigma^i Y)$$

(1)

$$= \sum_{i=0}^{3} (-1)^i \dim \text{per}_{\mathcal{M}} \mathcal{M}(X, \Sigma^i Y)$$

$$= \dim \text{per}_{\mathcal{M}} \mathcal{M}(X, Y) - \dim \text{per}_{\mathcal{M}} \mathcal{M}(X, \Sigma Y)$$

$$+ \dim \text{per}_{\mathcal{M}} \mathcal{M}(X, \Sigma^2 Y) - \dim \text{per}_{\mathcal{M}} \mathcal{M}(X, \Sigma^3 Y)$$

(2)

$$= \dim \text{Hom}_{\mathcal{M}}(X, Y) - \dim \text{Ext}^1_{\mathcal{M}}(X, Y)$$

$$+ \dim \text{Hom}_{\mathcal{M}}(Y, X) - \dim \text{Ext}^1_{\mathcal{M}}(Y, X)$$

$$= \langle [X], [Y] \rangle_\alpha$$

where the classes are now taken in $K_0(\text{mod} \ B)$. Equalities (1) and (2) are consequences of the 3-Calabi–Yau property of the category $\text{per}_{\mathcal{M}}$, cf. [23]. □

4. Dichotomy

Our aim in this part is to study the coefficients appearing in the definition of $X_{\mathcal{M}}$. In particular, we will prove that the phenomenon of dichotomy proved in [10] (see also [23]) remains true in this more general setting.

Recall that we write $x^e$ for $\prod_{i=1}^{n} X_{[e, P_i]}$ where $e \in K_0(\text{proj} \ B)$ and $[e : P_i]$ is the $i$th coefficient of $e$ in the basis $[P_1], \ldots, [P_n]$.

Lemma 4.1. For any $M \in \mathcal{C}$, we have

$$X_M = \sum_{e} \chi(\text{Gr}_e \mathcal{F}M) \prod_{i=1}^{n} x_i^{(S_i, e)_{\alpha}}.$$

Proof. We already know that this formula holds for indecomposable objects of $\mathcal{C}$, cf. section 2.2. Let us prove that it still holds for decomposable objects, by recursion on the number of indecomposable direct summands.

Let $M$ and $N$ be two objects in $\mathcal{C}$. As shown in [3], we have

$$\chi(\text{Gr}_g F(M \oplus N)) = \sum_{e+f=g} \chi(\text{Gr}_e \mathcal{F}M) \chi(\text{Gr}_f \mathcal{F}N).$$

Therefore, we have $X_{M \oplus N} = X_M X_N =$

$$\left( \sum_{e} \chi(\text{Gr}_e \mathcal{F}M) \prod_{i=1}^{n} x_i^{S_i, e}_{\alpha} \right) \left( \sum_{f} \chi(\text{Gr}_f \mathcal{F}N) \prod_{i=1}^{n} x_i^{S_i, f}_{\alpha} \right)$$

$$= \sum_{g} \chi(\text{Gr}_g \mathcal{F}(M \oplus N)) \prod_{i=1}^{n} x_i^{S_i, g}_{\alpha}$$

$$= \sum_{g} \chi(\text{Gr}_g F(M \oplus N)) \prod_{i=1}^{n} x_i^{S_i, g}_{\alpha}.$$

□

Lemma 4.2. Let $\xymatrix{ M \ar[r]^i & B \ar[r]^p & L \ar[r]^{\varepsilon} & \Sigma M \ar[r] & \Sigma L }$ be a triangle in $\mathcal{C}$, and let $U \xymatrix{ i_U^* \ar[r] & M }$ and $V \xymatrix{ i_V^* \ar[r] & L }$ be two morphisms whose images under $F$ are monomorphisms. Then the following conditions are equivalent:
i) There exists a submodule $E \subset FB$ such that $FV = (Fp)E$ and $FU = (Fi)^{-1}E$.

ii) There exist two morphisms $e : \Sigma^{-1}V \to U$ and $f : \Sigma^{-1}L \to U$ such that
   a) $(\Sigma^{-1}e)(\Sigma^{-1}i_V) = i_Ue$
   b) $e \in (T)$
   c) $i_Uf = \Sigma^{-1}e \in (\Sigma T)$.

iii) Condition ii) where, moreover, $e = f\Sigma^{-1}i_V$.

The following diagrams will help the reader parse the conditions:

![Diagram]

**Proof.** Assume condition ii) holds. Then, by a), there exists a morphism of triangles

![Diagram]

Take $E$ to be the image of the morphism $Fj$. The morphism $e$ factors through $\text{add } T$, so that we have $F\Sigma e = 0$ and the functor $F$ induces a commutative diagram

![Diagram]

whose rows are exact sequences. It remains to show that $FU = (Fi)^{-1}E$.

We have $FU \subset (Fi)^{-1}E$ since $(Fi)(Fi_U)$ factors through the monomorphism $E \to FB$. The existence of the morphism $Ff$ shows, via diagram chasing, the converse inclusion.

Conversely, let $E \subset FB$ be such that $FV = (Fp)E$ and $FU = (Fi)^{-1}E$. In particular, $FU$ contains $\text{Ker } Fi = \text{Im } F\Sigma^{-1}e$ so that $F\Sigma^{-1}e$ factors through $Fi_U$. This gives us the morphism $f$, satisfying condition c). Define the morphism $e$ as follows. There exists a triangle

![Triangle]

where $T_1,T_0$ belong to $\text{add } T$. Applying the functor $F$ to this triangle, we get an epimorphism $FT_0 \to FV$ with $FT_0$ projective. This epimorphism thus factors through the surjection $E \to FV$, and composing it with $E \to FB$ gives a
commutative square
\[
\begin{array}{c}
FT_0 \rightarrow FV \\
\downarrow \downarrow \\
FB \rightarrow FL.
\end{array}
\]

Since \(C(T, \Sigma T) = 0\), this commutative square lifts to a morphism of triangles
\[
\begin{array}{c}
\Sigma^{-1}V \rightarrow T_1 \rightarrow T_0 \rightarrow V \\
\downarrow \downarrow \downarrow \\
\Sigma^{-1}L \rightarrow M \rightarrow B \rightarrow L.
\end{array}
\]

The morphism \(T_1 \rightarrow M\) thus induced, factors through the morphism \(U \rightarrow M\).

Indeed, we have \(FU = (Fi)^{-1}E\) and the following diagram commutes:

\[
\begin{array}{c}
FM \rightarrow FB \\
\downarrow \downarrow \\
FT_1 \rightarrow FT_0 \\
\downarrow \downarrow \\
FU \rightarrow E.
\end{array}
\]

The morphism \(e\) is then given by the composition \(\Sigma^{-1}V \rightarrow T_1 \rightarrow U\).

Let us show that condition ii) implies condition iii). By hypothesis, we have

\[i_U e = (\Sigma^{-1}e)(\Sigma^{-1}i_V)\]

and

\[i_U f\Sigma^{-1}i_V \equiv (\Sigma^{-1}e)(\Sigma^{-1}i_V) \text{ mod } (\Sigma T).\]

Therefore, the morphism \(i_U (f\Sigma^{-1}i_V - e)\) belongs to the ideal \((\Sigma T)\). The morphism \(Fi_U\) is a monomorphism, so that the morphism \(h := f\Sigma^{-1}i_V - e\) lies in \((\Sigma T)\). There exists a morphism \(\Sigma^{-1}L \rightarrow U\) such that \(h = l\Sigma^{-1}i_V\):

\[
\begin{array}{c}
\Sigma^{-1}C \xrightarrow{e(T)} \Sigma^{-1}V \xrightarrow{\Sigma^{-1}i_V} \Sigma^{-1}L \xrightarrow{\Sigma^{-1}e} C \\
\downarrow 0 \downarrow h \downarrow \Sigma(T)v(l) \\
\Sigma^{-1}V \xrightarrow{\Sigma^{-1}i_V} \Sigma^{-1}L \xrightarrow{\Sigma^{-1}e} C
\end{array}
\]

Since the morphism \(\Sigma^{-1}C \rightarrow \Sigma^{-1}V\) lies in the ideal \((T)\), there exists a morphism of triangles

\[
\begin{array}{c}
\Sigma^{-1}C \rightarrow \Sigma^{-1}V \rightarrow \Sigma^{-1}L \rightarrow C \\
\downarrow \downarrow \downarrow \\
T_V^{1 \uparrow} \rightarrow \Sigma^{-1}V \rightarrow \Sigma T_V^{0} \rightarrow \Sigma T_V^{1}.
\end{array}
\]

The composition \(l\Sigma^{-1}i_V\) belongs to the ideal \((\Sigma T)\), so that the composition \(l(\Sigma^{-1}i_V)u\) vanishes. We thus have a morphism of triangles

\[
\begin{array}{c}
T_V^{1} \rightarrow \Sigma^{-1}V \rightarrow \Sigma T_V^{0} \rightarrow \Sigma T_V^{1} \\
\downarrow \downarrow \downarrow \\
\Sigma^{-1}C' \rightarrow \Sigma^{-1}L \rightarrow U \rightarrow C'.
\end{array}
\]
Therefore, we have \((\Sigma^{-1}i_V)(l - wv) = 0\), and there exists a morphism \(C \xrightarrow{\nu} U\) such that \(l - wv = \nu c\). The morphism \(l_0 = l - \nu c\) thus factors through \(\Sigma T_1\). Put \(f_0 = f - l_0\). We have
\[
f_0\Sigma^{-1}i_V = f\Sigma^{-1}i_V - l\Sigma^{-1}i_V + l_0\Sigma^{-1}i_V = e
\]
and
\[
i_Vf_0 = i_Vf - i_Vl_0 \\
\equiv i_Vf \mod (\Sigma T) \\
\equiv \Sigma^{-1}e \mod (\Sigma T).
\]

**Proposition 4.3.** Let \(L, M \in C\) be such that \(\dim \mathcal{C}(L, \Sigma M) = 1\). Let
\[
\Delta : M \xrightarrow{1} B \xrightarrow{\rho} L \xrightarrow{\varepsilon} \Sigma M
\]
and \(\Delta' : L \xrightarrow{1} B' \xrightarrow{\rho'} M \xrightarrow{\varepsilon'} \Sigma L\) be non-split triangles. Then conditions i) to iii) hold for the triangle \(\Delta\) if and only if they do not for the triangle \(\Delta'\).

**Proof.** Define maps
\[
\begin{align*}
(\Sigma^{-1}L, U) \oplus (\Sigma^{-1}L, M) & \xrightarrow{\alpha} \mathcal{C}(\Sigma^{-1}V, U) \oplus (\Sigma^{-1}V, M) \oplus \mathcal{C}(\Sigma T) (\Sigma^{-1}L, M) \\
(f, \eta) & \longmapsto (f\Sigma^{-1}i_V, iv f\Sigma^{-1}i_V - \eta \Sigma^{-1}i_V, iv f - \eta)
\end{align*}
\]
and
\[
\begin{align*}
(\Sigma^{-1}U, L) \oplus (\Sigma^{-1}M, L) & \xrightarrow{\beta'} (\Sigma^{-1}U, V) \oplus (\Sigma^{-1}M, V) \oplus (\Sigma T)(\Sigma^{-1}M, L) \\
(iv e' + g'\Sigma^{-1}i_V + iv f'\Sigma^{-1}i_V, -g' - iv f') & \longmapsto (e', f', g').
\end{align*}
\]
Since the morphism space \(\mathcal{C}(L, \Sigma M)\) is one-dimensional, the morphism \(\varepsilon\) satisfies condition iii) if and only if the composition
\[
\beta : \text{Ker} \alpha \xrightarrow{\beta} (\Sigma^{-1}L, U) \oplus (\Sigma^{-1}L, M) \xrightarrow{\beta} (\Sigma^{-1}L, M)
\]
does not vanish. Assume condition iii) to be false for the triangle \(\Delta\). This happens if and only if the morphism \(\beta\) vanishes, if and only if its dual \(D\beta\) vanishes. Since the category \(C\) is 2-Calabi–Yau, lemma 3.3 implies that the morphism \(D\beta\) is isomorphic to the morphism:
\[
\beta' : (\Sigma^{-1}M, L) \xrightarrow{\beta'} (\Sigma^{-1}U, L) \oplus (\Sigma^{-1}M, L) \xrightarrow{\text{Coker} \alpha'} \text{Coker} \alpha'.
\]
Therefore, \(\beta'(\Sigma^{-1}e) = 0\) is equivalent to \(\Sigma^{-1}e\) being in \(\text{Im} \alpha'\), which is equivalent to the existence of three morphisms \(e', f', g'\) as in the diagram
\[
\begin{array}{ccc}
\Sigma^{-1}M & \xrightarrow{g'} & L \\
\Sigma^{-1}i_V & \downarrow & \downarrow i_V \\
\Sigma^{-1}U & \xrightarrow{e'} & V \\
\end{array}
\]
such that
\[
\begin{align*}
e' & \in (T) \\
g' & \in (\Sigma T) \\
\Sigma^{-1}e' & = iv f' + g' \\
i_V e' & = (\Sigma^{-1}e')(\Sigma^{-1}i_V).
\end{align*}
\]
We have thus shown that condition iii) does not hold for the triangle \(\Delta\) if and only if condition ii) holds for the triangle \(\Delta'\). \(\square\)
5. THE MULTIPLICATION FORMULA

We use sections 2 and 4 to prove the multiplication formula, and apply it to prove conjecture 2 in [9].

5.1. Proof of theorem 1.4. We use the same notations as in the statement of theorem 1.4.

Define, for any classes \(e, f, g\) in the Grothendieck group \(K_0(\text{mod } B)\), the following varieties:

\[
X_{e,f} = \{ E \subset FB \text{ s.t. } [(Fi)^{-1}E] = e \text{ and } [(Fp)E] = f \}, \\
Y_{e,f} = \{ E \subset FB' \text{ s.t. } [(Fi')^{-1}E] = f \text{ and } [(Fp')E] = e \}, \\
X^{g}_{e,f} = X_{e,f} \cap \text{Gr}_g(FB) \\
Y^{g}_{e,f} = Y_{e,f} \cap \text{Gr}_g(FB').
\]

We thus have

\[
\text{Gr}_g(FB) = \coprod_{e,f} X^{g}_{e,f} \quad \text{and} \quad \text{Gr}_g(FB') = \coprod_{e,f} Y^{g}_{e,f}.
\]

Moreover, we have

\[
\chi(\text{Gr}_e(FM) \times \text{Gr}_f(FL)) = \chi(X_{e,f} \sqcup Y_{e,f}) = \chi(X_{e,f}) + \chi(Y_{e,f}) = \sum_{g} \left( \chi(X^{g}_{e,f}) + \chi(Y^{g}_{e,f}) \right).
\]

where the first equality is a consequence of the dichotomy phenomenon as follows: Consider the map

\[
X_{e,f} \sqcup Y_{e,f} \to \text{Gr}_e(FM) \times \text{Gr}_f(FL)
\]

which sends a submodule \(E\) of \(FB\) to the pair of submodules \((Fi)^{-1}E, (Fp)E\).

By proposition 4.3, it is surjective, and, as shown in [8], its fibers are affine spaces.

Lemma 5.1. Let \(e, f\) and \(g\) be classes in \(K_0(\text{mod } \text{End}_C(T))\). Assume that \(X^{g}_{e,f}\) is non-empty. Then, we have

\[
\sum \langle S_i, g \rangle a[P_i] - \text{coind } B = \sum \langle S_i, e + f \rangle a - \text{coind } M - \text{coind } L.
\]

Proof. Let \(E\) be a submodule of \(FB\) in \(X^{g}_{e,f}\). Let \(U \xrightarrow{i_U} M\) and \(V \xrightarrow{i_V} L\) be two morphisms in the category \(C\) such that \(FU \simeq (Fi)^{-1}E, FV \simeq (Fp)E\) and the images of \(i_U\) and \(i_V\) in \(\text{mod } B\) are isomorphic to the inclusions of \(FU\) in \(FM\) and \(FV\) in \(FL\) respectively. Let \(K \in C\) be a lift of the kernel of \(Fi\). By proposition 2.2, the following equality holds:

\[
\text{coind } B = \text{coind } M + \text{coind } L - \text{coind } K - \text{coind}(\Sigma K).
\]

By diagram chasing, the kernel of \(Fi\) is also a kernel of the induced morphism from \(FU\) to \(E\). Therefore, in \(K_0(\text{mod } B)\), we have

\[
\text{coind } K = \text{coind } (\Sigma K) - \text{coind}(\Sigma K).
\]

We have the following equalities:

\[
\sum \langle S_i, FK \rangle a[P_i] = \text{coind } K - \text{ind } K \quad \text{(by lemma 2.3)}
\]

\[
= \text{coind } K + \text{coind}(\Sigma K) \quad \text{(by lemma 2.1)}.
\]

Equality (2) thus yields

\[
\sum \langle S_i, g \rangle a[P_i] = \sum \langle S_i, e + f \rangle a[P_i] - \text{coind } K - \text{coind}(\Sigma K).
\]

It only remains to sum equalities (1) and (3) to finish the proof. \(\square\)
Proof of theorem 1.4.

Using lemma 4.1, we have

\[
X_M X_L = \varepsilon^{-\text{coind} M - \text{coind} L} \sum_{e, f} \chi(\text{Gr}_e F M) \chi(\text{Gr}_f F L) \prod_{i=1}^n x_i^{(S_i, e+f)} a,
\]

\[
X_B = \varepsilon^{-\text{coind} B - \text{coind} L} \sum_g \chi(\text{Gr}_g F B) \prod_{i=1}^n x_i^{(S_i, g)} a
\]

\[
X_{B'} = \varepsilon^{-\text{coind} B'} \sum_g \chi(\text{Gr}_g F B') \prod_{i=1}^n x_i^{(S_i, g)} a.
\]

Therefore

\[
X_M X_L = \varepsilon^{-\text{coind} M - \text{coind} L} \sum_{e, f} \chi(\text{Gr}_e (F M)) \chi(\text{Gr}_f (F L)) \prod_{i=1}^n x_i^{(S_i, e+f)} a
\]

\[
= \varepsilon^{-\text{coind} B - \text{coind} L} \sum_{e, f, g} \chi(\text{Gr}_g (F B)) \prod_{i=1}^n x_i^{(S_i, g)} a
\]

\[
= \varepsilon^{-\text{coind} B} \sum_{e, f, g} \chi(\text{Gr}_g (F B')) \prod_{i=1}^n x_i^{(S_i, g)} a
\]

\[
= X_B + X_{B'}.
\]

\[
\square
\]

5.2. Consequences. Let \( Q \) be a finite acyclic connected quiver, and let \( C \) be the cluster category associated to \( Q \).

An object of \( C \) without self-extensions is called rigid. An object of \( C \) is called basic if its indecomposable direct summands are pairwise non-isomorphic. For a basic cluster-tilting object \( T \) of \( C \), let \( Q_T \) denote the quiver of \( \text{End} (T) \), and \( A_{Q_T} \) the associated cluster algebra.

Proposition 5.2. A cluster character \( \chi \) on \( C \) with values in \( \mathbb{Q}(x_1, \ldots, x_n) \) which sends a basic cluster-tilting object \( T \) of \( C \) to a cluster \( A_{Q_T} \) sends any cluster-tilting object \( T' \) of \( C \) to a cluster of \( A_{Q_T} \), and any rigid indecomposable object to a cluster variable.

Proof. Since the tilting graph of \( C \) is connected, cf. [3, proposition 3.5], we can prove the first part of the proposition by recursion on the minimal number of mutations linking \( T' \) to \( T \). Let \( T'' = T_1'' \oplus \cdots \oplus T_n'' \) be a basic cluster-tilting object, whose image under \( \chi \) is a cluster of \( A_{Q_T} \). Assume that \( T' = T_1' \oplus T_2' \oplus \cdots \oplus T_n' \) is the mutation in direction 1 of \( T'' \). Since \( \chi \) is a cluster character, it satisfies the multiplication formula, and theorem 6.1 of [3] shows that the mutation, in direction 1, of the cluster \( \langle \chi(T_1''), \ldots, \chi(T_n'') \rangle \) is the cluster \( \langle \chi(T_1'), \chi(T_2'), \ldots, \chi(T_n') \rangle \). We have thus proved that the image under \( \chi \) of any cluster-tilting object is a cluster. It is proved in [3, proposition 3.2] that any rigid indecomposable object of \( C \) is a direct summand of a basic cluster-tilting object. Therefore, the image under \( \chi \) of any rigid indecomposable object is a cluster variable of \( A_{Q_T} \). \( \square \)
Remark: As a corollary of the proof of proposition 5.2, a cluster character is characterised, on a set of representatives for the isoclasses of indecomposable rigid objects of $\mathcal{C}$ by the image of each direct summand of any given cluster-tilting object. In fact, using [3, 1.10], this remains true in the more general context of [3]: Let $\mathcal{C}$ be a Hom-finite triangulated 2-Calabi–Yau category having maximal rigid objects without loops nor strong 2-cycles. Denote by $n$ the number of non-isomorphic indecomposable direct summands of any maximal rigid object.

**Lemma 5.3.** Let $\chi_1$ and $\chi_2$ be two cluster characters on $\mathcal{C}$ with values in $\mathbb{Q}(x_1, \ldots, x_n)$. Assume that $\chi_1$ and $\chi_2$ coincide on all indecomposable direct summands of a cluster-tilting object $T$ in $\mathcal{C}$. Then $\chi_1$ and $\chi_2$ coincide on all direct summands of the cluster-tilting objects in $\mathcal{C}$ which are obtained from $T$ by a finite sequence of mutations.

The following corollary was conjectured for the finite case in [9]: Let $\mathcal{C}$ be the cluster category of the finite acyclic quiver $Q$.

**Corollary 5.4.** Let $T$ be any basic cluster-tilting object in $\mathcal{C}$, and let $Q_T$ denote the quiver of $\text{End}(T)$. Denote by $T$ a set of representatives for the isoclasses of indecomposable rigid objects of $\mathcal{C}$. Then $X^T$ induces a bijection from the set $T$ to the set of cluster variables of the associated cluster algebra $\mathcal{A}_{Q_T}$, sending basic cluster-tilting objects to clusters.

**Proof.** In view of theorem 1.4, proposition 5.2 shows that the map $X^T$ sends rigid indecomposable objects to cluster variables and cluster-tilting objects to clusters. It remains to show that it induces a bijection. This follows from [10, theorem 4], where it is proved for the Caldero–Chapoton map $X^{kQ}$.

As in the proof of proposition 5.2, we proceed by induction on the minimal number of mutations linking $T$ to $kQ$.

Let $T'$ be a basic cluster-tilting object such that the map $X^{T'}$ induces a bijection from the set $T$ to the set of cluster variables. Assume that $T'$ is the mutation in direction 1 of $T'$. Denote by $f$ the canonical isomorphism from $\mathcal{A}_{Q_{T'}}$ to $\mathcal{A}_{Q_T}$. Theorem 6.1 of [3] shows that the two cluster characters $X^T$ and $f \circ X^{T'}$ coincide on the indecomposable direct summands of $\Sigma T$. Therefore, they coincide on all rigid objects and the map $X^T$ also induces a bijection. □

**Remark:** We have shown that, for any basic cluster-tilting object $T$, we have a commutative diagram

\[
\begin{array}{ccc}
T & \xrightarrow{X^T} & A_Q \\
\downarrow & & \downarrow \\
\mathcal{A}_{Q_T} & \xleftarrow{\cong} & \mathcal{A}_{Q_T}
\end{array}
\]

where the arrow on the left side is the Caldero–Chapoton map.

6. **Examples**

6.1. **The cluster category $\mathcal{C}_{A_4}$**. The Auslander–Reiten quiver of $\mathcal{C}_{A_4}$ is

\[
\begin{array}{ccc}
\Sigma T_1 & \xrightarrow{M_C} & T_1 \\
\downarrow & & \downarrow \\
\Sigma T_2 & \xrightarrow{\Sigma T_4} & T_3 \\
\downarrow & & \downarrow \\
\Sigma T_4 & \xrightarrow{\Sigma T_1} & T_3
\end{array}
\]
The object \( T := T_1 \oplus T_2 \oplus T_3 \oplus T_4 \) is cluster-tilting. Indeed, it is obtained from the image of the \( kQ \)-projective module \( kQ \) in \( C_{A_4} \) by the mutation of the third vertex.

The quiver of \( B = \text{End}_{C_{A_4}}(T) \) is

\[
\begin{array}{ccc}
1 & \overset{\gamma}{\rightarrow} & 4 \\
\downarrow & & \downarrow \\
2 & \overset{\alpha}{\rightarrow} & 3 \\
\end{array}
\]

with relations \( \beta \alpha = \gamma \beta = \alpha \gamma = 0 \). For \( i = 1, \ldots, n \), let \( P_i \) be the image of \( T_i \) in \( \text{mod} \, B \), let \( I_i \) be the image of \( \Sigma^2 T_i \) and let \( S_i \) be the simple top of \( P_i \). Let \( M \) be the finite-dimensional \( B \)-module given by:

\[
\begin{array}{ccc}
1 & \overset{\gamma}{\rightarrow} & 4 \\
\downarrow & & \downarrow \\
2 & \overset{\alpha}{\rightarrow} & 3 \\
\end{array}
\]

The shape and the relations of the AR-quiver of \( B \) are obtained from the ones of \( C_{A_4} \) by deleting the vertices corresponding to the objects \( \Sigma T_i \) and all arrows ending to or starting from these vertices.

Let \( M_C \) be an indecomposable lift of \( M \) in \( C_{A_4} \). The triangles

\[
T_3 \rightarrow T_2 \rightarrow M_C \rightarrow \Sigma T_3 \quad \text{and} \quad T_1 \rightarrow T_4 \rightarrow \Sigma^{-1} M_C \rightarrow \Sigma T_1
\]

allows us to compute the index and coindex of \( M_C \):

\[
\text{ind} \, M_C = [P_2] - [P_3] \\
\text{coind} \, M_C = [P_1] - [P_4].
\]

Up to isomorphism, the submodules of \( M \) are 0, the simple \( S_1 \), and \( M \) itself. We thus have

\[
X_{M_C} = \frac{x_4 x_2 + x_4 + x_3 x_1}{x_1 x_2}.
\]

6.2. The cluster category \( C_{D_4} \). The Auslander–Reiten quiver of \( C_{D_4} \) is

The object \( T := T_1 \oplus T_2 \oplus T_3 \oplus T_4 \) is cluster-tilting.
The quiver of $B = \text{End}_{\mathcal{C}_{D_4}}(T)$ is

\[
\begin{array}{c}
\quad 1 \\
\downarrow \\
0 \\
\quad 2 \\
\uparrow \\
3 \\
\end{array}
\]

with the following relations: Any composition with the middle arrow vanishes, and the square is commutative.

For $i = 1, \ldots, n$, let $P_i$ be the image of $T_i$ in $\text{mod} \ B$, let $I_i$ be the image of $\Sigma^2T_i$ and let $S_i$ be the simple top of $P_i$. Let $M$ and $N$ be the finite-dimensional $B$-modules given by:

\[
M : \begin{array}{c}
k \\
\downarrow \\
k \\
\downarrow \\
k \\
\end{array} \quad N : \begin{array}{c}
k \\
\downarrow \\
k \\
\downarrow \\
k \\
\end{array}
\]

As in the previous example, one can easily compute the AR-quiver of $B$.

\[
\begin{array}{c}
P_3 = I_0 \\
\vdots \\
P_1 \quad S_2 \\
S_3 \quad P_2 \\
S_1 \quad P_1 \\
S_0 \quad I_2 \\
\end{array}
\]

The submodules of $M$ are, up to isomorphism, $0$, $S_1$, $S_2$, $S_1 \oplus S_2$ and $M$. Let $M_C$ be an indecomposable lift of $M$ in $\mathcal{C}_{D_4}$. Either by using $\text{add} T$-approximations and $\text{add} \Sigma T$-approximations or by [21], section 5.2, one can compute the triangles

$T_3 \rightarrow T_0 \rightarrow M_C \rightarrow \Sigma T_3$ and $T_1 \oplus T_2 \rightarrow T_0 \rightarrow \Sigma^{-1}M \rightarrow \Sigma T_1 \oplus \Sigma T_2$.

We thus have

\[
\text{ind} \ M_C = [P_0] - [P_3], \quad \text{coind} \ M_C = [P_1] + [P_2] - [P_0]
\]

and

\[
X_{M_C} = \frac{(x_0 + x_3)^2 + x_1x_2x_3}{x_0x_1x_2}.
\]
