Abstract

We suppose that data of a generalized canonical correlation analysis are i.i.d. observations of a random vector $Z$ which are taken sequentially. We define a recursive method of sequential estimation of the factors. This can be applied also when there is a great amount of non random data vectors.

Key Words and Phrases: Stochastic approximation, Canonical correlation analysis

1 Introduction

Consider the generalized canonical correlation analysis (gCCA) as defined by Carroll (1968). Suppose that data are i.i.d. observations of a random vector $Z$ which are taken sequentially: at time $n$, $Z_n$ is observed. We define a recursive method of sequential estimation of the general and canonical factors of gCCA by using a stochastic approximation process derived from that of Krasulina (1970), whose convergence has been studied by Bouamaine and Monnez (1998). This method can be used also when there is a great amount of non random data vectors: at time $n$, a data vector is randomly chosen.

Numerical results for this type of algorithm in the case of principal component analysis are given by Bouamaine (1996). An implementation is in progress of an algorithm corresponding to a multiple factorial analysis, which treats the same type of data as gCCA, and also a number of simulations are being made.

We present gCCA in the second section, stochastic approximation of the parameter of a linear regression function in the third and stochastic approximation of the factors in the fourth. In the following, $\rho$ denotes a linear correlation coefficient, $A'$ the transposed matrix of $A$, $\lambda_{\text{min}}(A)$ the smallest eigenvalue of $A$, $\mathbb{R}^p$ the dual space of $\mathbb{R}^p$. The abbreviation a.s. means almost surely.
2 Generalized canonical correlation analysis of a random vector

Consider two random vectors $Z^1$ and $Z^2$ defined on the same probability space and suppose that there is no affine relation between the components of $Z = (Z^1, Z^2)$. The canonical correlation analysis (CCA) consists in determining at step $l \in \{1, ..., r\}$ for $k = 1, 2$ a linear combination of variance 1 of the centered components of $Z^k$, $V^k_l = (\eta^k_l)'(Z^k - E[Z^k])$, uncorrelated with $V^k_{l-1}, ..., V^k_1$, which maximizes $\rho(V^1_l, V^2_l)$. This analysis permits one to put into relation two sets of variables or to explain one set of variables by the other.

A generalization of CCA to three or more sets of variables is gCCA. As it will be seen, gCCA can be interpreted as a principal component analysis (PCA) of a random vector $Z = (Z^1, ..., Z^q)$ in $\mathbb{R}^p$, $Z^1, ..., Z^q$ being $q$ random vectors which take in some sense a similar part in the determination of the factors.

More precisely, suppose that the set of components of a random vector $Z$ in $\mathbb{R}^p$ is divided into $q$ sets of real random variables $\{Z^{k1}, ..., Z^{km_k}\}, k = 1, ..., q, \sum_{k=1}^q m_k = p$. Denote $Z^k$ the random vector in $\mathbb{R}^{m_k}$ whose components are $Z^{k1}, ..., Z^{km_k}$. Suppose that there is no affine relation between the components of $Z$.

Consider the following problem: for $l = 1, ..., r$, determine at step $l$ a linear combination of all the centered variables $Z^{k_i}, U_l = (\theta_l)'(Z - E[Z]), \theta_l \in \mathbb{R}^{p*}$, named $l^{th}$ general component, which is of variance 1 and uncorrelated with the preceding ones, and for $k = 1, ..., q$, a linear combination of variance 1 of the centered variables...
of the $k^{th}$ set, $V_i^k = (\eta_i^k)'(Z^k - E[Z^k]), \eta_i^k \in \mathbb{R}^{m_k \times 1}$, named $l^{th}$ canonical component of the $k^{th}$ set, which maximize $\sum_{k=1}^q \rho^2(U_1, V_i^k)$. $\theta_l$ is named the $l^{th}$ general factor and $\eta_i^k$ the $l^{th}$ canonical factor of the $k^{th}$ set.

Remark that when $m_k = 1$ for $k = 1, ..., p$ ($q = p$), this analysis is equivalent to the normed principal component analysis of $Z$ i.e. PCA of $Z$ with the inner product in $\mathbb{R}^p$ defined by the weight matrix

$$
\begin{pmatrix}
\frac{1}{(\sigma^1)^2} \\
\vdots \\
\frac{1}{(\sigma^p)^2}
\end{pmatrix}, (\sigma^k)^2 = E \left[ (Z^k - E[Z^k])^2 \right].
$$

In this PCA, the random variables $Z^1, ..., Z^p$ play in some sense a similar part in the definition of the squared distance in $\mathbb{R}^p$ between two data vectors $Z(\omega_1)$ and $Z(\omega_2)$:

$$
d^2(Z(\omega_1), Z(\omega_2)) = \sum_{k=1}^p \left( \frac{Z^k(\omega_1) - Z^k(\omega_2)}{\sigma^k} \right)^2.
$$

In the general case, denote $C^k$ the covariance matrix of $Z^k$, $C$ that of $Z$ and define the covariance matrices

$$
C^{kl} = E \left[ (Z^k - E[Z^k]) (Z^l - E[Z^l])' \right]
$$

$$
C^{k.} = E \left[ (Z^k - E[Z^k]) (Z - E[Z])' \right] = (C^{k1}...C^{kq}).
$$
Let $M$ be the block diagonal matrix

\[
M = \begin{pmatrix}
(C^1)^{-1} & & & \\
& \ddots & & \\
& & \ddots & \\
& & & (C^q)^{-1}
\end{pmatrix}
\]

Let $\theta_i = (\theta_{i1}, ..., \theta_{ip})', \theta_i^k \in \mathbb{R}^{m_k \times *}$ for $k = 1, ..., q$. Consider the matrix $B = MC$ which can be divided into $q^2$ blocks, the block $(k,l)$ being the $(m_k, m_l)$ matrix $(C^k)^{-1}C^{kl}$.

**Theorem 1** $\theta_i$ is a $C$-normed eigenvector of the matrix $B = MC$ corresponding to the $l^{th}$ greatest eigenvalue $\lambda_l$ and for $k = 1, ..., q$, there exists $\alpha_i^k \in \mathbb{R}$ such that $\eta_i^k = \alpha_i^k \theta_i^k$.

**Proof.** Assume $U_i$ to be determined. Then: $\sum_{k=1}^q \rho^2(U_i, V_i^k)$ max $\iff \rho^2(U_i, V_i^k)$ max, $k = 1, ..., q$. Thus $V_i^k$ is obtained by making the linear regression of $U_i$ with respect to $Z^k$. Therefore there exists $\beta_i^k \in \mathbb{R}$ such that

\[
V_i^k = \beta_i^k \Pi^k U_i, \quad \Pi^k U_i = (Z^k - E[Z^k])' b_i^k, \\
b_i^k = (C^k)^{-1} E [(Z^k - E[Z^k])U_i] = (C^k)^{-1} C^k \theta_i.
\]

\[
\sum_{k=1}^q \rho^2(U_i, V_i^k) = \sum_{k=1}^q E [U_i \Pi^k U_i] = \sum_{k=1}^q (\theta_i)(C^k)'(C^k)^{-1} C^k \theta_i = (\theta_i)' CMC \theta_i.
\]
\[ \theta_l \text{ maximizes } (\theta_l)'CMC\theta_l \text{ under the constraints } \theta_l'C\theta_j = 0, \ j = 1, 2, ..., l-1 \]
and \( \theta_l'C\theta_l = 1. \) Then \( \theta_l \) is eigenvector of \( MC \) corresponding to the eigenvalue \( \lambda_l \) and
\[ \eta_l^k = \beta_l^k b_l^k = \beta_l^k (C^k)^{-1} C^k : \theta_l = \beta_l^k \lambda_l \theta_l^k. \]

Remark that \( \theta_l \) is the \( l^{th} \) factor of the principal component analysis of \( Z, \) the inner product in \( \mathbb{R}^p \) being defined by \( M. \) In this PCA, the random vectors \( Z^1, ..., Z^q \) play in some sense a similar part in the definition of the squared distance in \( \mathbb{R}^p \) between two data vectors \( Z(\omega_1) \) and \( Z(\omega_2): \)
\[ d^2(Z(\omega_1), Z(\omega_2)) = \sum_{k=1}^{q} (Z^k(\omega_1) - Z^k(\omega_2))'(C^k)^{-1} (Z^k(\omega_1) - Z^k(\omega_2)). \]

Remark too that this analysis in the case \( q = 2 \) is the usual canonical correlation analysis. \( \theta_l = \begin{pmatrix} \theta_l^1 \\ \theta_l^2 \end{pmatrix} \) is eigenvector of \( \begin{pmatrix} I & (C^1)^{-1}C^{12} \\ (C^2)^{-1}C^{21} & I \end{pmatrix} ; \theta_l^k \) is colinear to the \( l^{th} \) canonical factor in \( Z^k \) for \( k = 1, 2. \)

3 Stochastic approximation of a linear regression function

3.1 Proposition

Let \( R \) be a random vector in \( \mathbb{R}^r \) and suppose:

(H1) There is no affine relation between the components of \( R. \)

Let \( S \) be a random vector in \( \mathbb{R}^s. \) Denote \( \text{Covar}R \) the covariance matrix of \( R \) and \( \text{Covar}(R, S) = E [(R - E[R])(S - E[S])'] \). Let \( A \) be a \((r, s)\) matrix and \( D \) a \((s, 1)\) matrix. \((\text{Covar}R)^{-1}\text{Covar}(R, S)\) is the solution in \( A \) of the following linear regression
problem: find \((A, D)\) such that \(E \left[ \|S - A'R - D\|^2 \right] \) be minimal, \(\|\cdot\|\) being the usual euclidean norm.

Denote \(A_1\) the \((r + 1, s)\) matrix such that \(A'_1 = \begin{pmatrix} A' & D \end{pmatrix}\) and \(R_1\) the random vector in \(\mathbb{R}^{r+1}\) such that \(R'_1 = \begin{pmatrix} R' & 1 \end{pmatrix}\). \(E[R_1R'_1]\) is positive definite by H1. \((Covar R)^{-1}Covar(R, S)\) can be obtained as it follows.

**Proposition 2** \(A = (Covar(R))^{-1}Covar(R, S)\) and \(D = E[S] - A'E[R]\) form the solution of the linear system \(E[R_1R'_1]A_1 = E[R_1S']\).

### 3.2 Stochastic approximation of \(A_1\)

Consider an i.i.d sample \(((R_n, S_n))\) of \((R, S)\). Denote for all \(n\) \(R_{1n}\) the random vector in \(\mathbb{R}^{r+1}\) such that \(R'_{1n} = \begin{pmatrix} R'_n & 1 \end{pmatrix}\). Consider the stochastic approximation process \((A_{1n}, n \geq 1)\) of \(A_1 = (E[R_1R'_1])^{-1}E[R_1S']\) in the set of \((r + 1, s)\) matrices such that

\[
A_{1,n+1} = A_{1n} - a_n(R_{1n}R'_{1n}, A_{1n} - R_{1n}S'_n), \quad a_n \in \mathbb{R}^{++}.
\]

Denote \(A_{1n} = \begin{pmatrix} A_n \cr D_n \end{pmatrix}\), \(A_n\) and \(D_n\) being respectively a \((r, s)\) and a \((s, 1)\) random matrix. \((A_n, n \geq 1)\) is a stochastic approximation process of \(A = (Covar(R))^{-1}Covar(R, S)\).

We use in the proof of the convergence the Hilbert-Schmidt inner product \(\langle ., . \rangle\) and norm \(\|\cdot\|\) in the set of \((r+1, s)\) matrices: \(\langle A, B \rangle = \text{Trace}(A'B) = \sum_{i=1}^{r+1} \sum_{j=1}^{s} A(i, j)B(i, j)\).

Suppose:

\((H2)\) \((R, S)\) has 4th order moments.
(H3) $a_n > 0, \ \sum_1^\infty a_n = \infty, \ \sum_1^\infty a_n^2 < \infty$.

(H3') $(a_n = a \frac{1}{n^\alpha}, \ a > 0, \ \frac{2}{3} < \alpha < 1) \ or \ (a_n = a \frac{1}{n}, \ a > \frac{1}{2\lambda_{\text{min}}(E[R_1 R_1'])})$.

**Theorem 3** Assume H1, H2, H3; then $\|A_{1n} - A_1\|$ and $\|A_n - A\|$ converge to 0 a.s. and in $L^2$; if H3 is replaced by H3', then moreover $\sum_1^\infty a_n \|A_{1n} - A_1\| < \infty$ and $\sum_1^\infty a_n \|A_n - A\| < \infty$ a.s.

**Proof.** Denote $B_n = R_{1n}R_{1n}', \ F_n = R_{1n}S_{n}', \ B = E[R_1 R_1'], \ F = E[R_1 S']$. As $A_1 = B^{-1}F$, we have:

$$A_{1n+1} - A_1 = A_{1n} - A_1 - a_n B(A_{1n} - A_1) - a_n U_n,$$

$$U_n = (B_n - B)A_{1n} + F - F_n.$$

$$\|A_{1n+1} - A_1\|^2 = \|A_{1n} - A_1\|^2 + a_n^2 \|B(A_{1n} - A_1)\|^2 + a_n^2 \|U_n\|^2$$

$$-2a_n \langle A_{1n} - A_1, B(A_{1n} - A_1) \rangle - 2a_n \langle A_{1n} - A_1, U_n \rangle$$

$$+ 2a_n^2 \langle B(A_{1n} - A_1), U_n \rangle.$$

Denote $\mathcal{T}_n$ the $\sigma$-field generated by $(R_j, S_j), \ j < n$ and $A_{11}$. As $E(U_n | \mathcal{T}_n) = 0$, we have:

$$E\left(\|A_{1n+1} - A_1\|^2 \mid \mathcal{T}_n\right) \leq \|A_{1n} - A_1\|^2 \left(1 + a_n^2 \|B\|^2\right) + a_n^2 E\left(\|U_n\|^2 \mid \mathcal{T}_n\right)$$

$$-2a_n \langle A_{1n} - A_1, B(A_{1n} - A_1) \rangle.$$

By H2, there exist $c$ and $d > 0$ such that:

$$E(\|U_n\|^2 \mid \mathcal{T}_n) = E\left(\|(B_n - B)A_{1n} + (F - F_n)\|^2 \mid \mathcal{T}_n\right) \leq c \|A_{1n} - A_1\|^2 + d.$$
Denote $M^{(j)}$ the $j^{th}$ column of a matrix $M$ and $\lambda$ the smallest eigenvalue of $B$.

Then:

$$\langle A_{1n} - A_1, B(A_{1n} - A_1) \rangle = \sum_{j=1}^s \langle A_{1n}^{(j)} - A_1^{(j)}, B(A_{1n}^{(j)} - A_1^{(j)}) \rangle$$

$$\geq \lambda \sum_{j=1}^s \| A_{1n}^{(j)} - A_1^{(j)} \|^2 = \lambda \| A_{1n} - A_1 \|^2.$$

Therefore:

$$E \left( \|A_{1,n+1} - A_1\|^2 \mid T_n \right) \leq (1 + \|B\|^2 a_n^2 + c\|B\|^2) \|A_{1n} - A_1\|^2 + da_n^2 - 2\lambda a_n \|A_{1n} - A_1\|^2.$$

By H3, applying the Robbins-Siegmund lemma (1971) gives the a.s. convergence of $\|A_{1n} - A_1\|$ and of $\sum_1^\infty a_n \|A_{1n} - A_1\|^2$. As $\sum_1^\infty a_n = \infty$, we have $\|A_{1n} - A_1\| \to 0$ a.s. Taking the expectation of $E \left( \|A_{1,n+1} - A_1\|^2 \mid T_n \right)$ gives in the same way $E \left[ \|A_{1n} - A_1\|^2 \right] \to 0$.

Thus there exist $N \in \mathbb{N}$ and $f > 0$ such that for $n > N$:

$$E \left[ \|A_{1,n+1} - A_1\|^2 \right] \leq (1 - 2\lambda a_n)E \left[ \|A_{1n} - A_1\|^2 \right] + fa_n^2.$$

Applying for instance lemmas 2 and 3 in Monnez (1992) gives for $a_n = \frac{a}{n^\alpha}$ with $0 < \alpha < 1$, or $\alpha = 1$ and $a > \frac{1}{2\lambda}$, $\lim_{a_n \to \infty} E \left[ \|A_{1n} - A_1\|^2 \right] < \infty$. Hence there exists $g > 0$ such that

$$\sum_1^\infty a_n E \left[ \|A_{1n} - A_1\| \right] \leq g \sum_1^\infty a_n^\frac{3}{\alpha} < \infty$$

for $\alpha > \frac{2}{3}$, it follows that $\sum_1^\infty a_n \|A_{1n} - A_1\| < \infty$ a.s. ■
4 Stochastic approximation of general factors

4.1 Definition of the process

Let \((Z_1^n, ..., Z_q^n), n \geq 1\) be an i.i.d. sample of the random vector \(Z = (Z_1, ..., Z_q)\) in \(\mathbb{R}^p\). For \(k = 1, ..., q\) and \(n \geq 1\), let

\[
\overline{Z}_n^k = \frac{1}{n} \sum_{i=1}^{n} Z_i^k, \quad M_n^k = \frac{1}{n} \sum_{i=1}^{n} Z_i^k Z_i^{k'} - \overline{Z}_n^k (\overline{Z}_n^k)' \;
\]

\(M_n^k\) is a consistent estimator of the covariance matrix \(C^k\) of \(Z^k\). For \(n \geq 1\), define the block-diagonal \((p, p)\) matrix

\[
M_n = \begin{pmatrix} 
M_1^1 \\
& \ddots \\
& & \ddots \\
& & & M_q^q 
\end{pmatrix} 
\]

\(M_n\) is a consistent estimator of \(M^{-1}\). Denote \((., .)_n\) the inner product defined by \(M_n\) in the dual space \(\mathbb{R}^{p^*}\) of \(\mathbb{R}^p\) and \(\|., .\|_n\) the associated norm.

In order to estimate \(B_{ij} = (C^i)^{-1}C^{ij}\) for \(i = 1, ..., q\) and \(j \neq i\), define the stochastic approximation processes \((B_{ij}^n)\) in the set of \((m_i + 1, m_j)\) matrices in the same way as in paragraph 3.2, \((F_{ij}^n)\) in the set of \((m_j, 1)\) matrices and \((B_{ii}^n)\) in the set of \((m_i, m_i)\)
matrices:
\[
B_{1,n+1}^{ij} = B_{1n}^{ij} - a_n \left( Z_{1n}^i (Z_{1n}^i)' B_{1n}^{ij} - Z_{1n}^i (Z_{1n}^j)' \right),
\]
\[
Z_{1n}^i = \begin{pmatrix} Z_n^i \\ 1 \end{pmatrix}, \quad B_{1n}^{ij} = \begin{pmatrix} B_n^{ij} \\ (F_n^{ij})' \end{pmatrix}.
\]

Define in the set of \((p, p)\) matrices the stochastic approximation process \((B_n)\) of the matrix \(B = MC\) such that the block \((i, j)\) of \(B_n\) is \(B_n^{ij}\):
\[
B_n = \begin{pmatrix} I & B_n^{12} & \cdots & B_n^{1q} \\ \vdots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \vdots \\ B_n^{q1} & B_n^{q2} & \cdots & I \end{pmatrix}
\]

In order to estimate \(r\) general factors of GCCA, define for \(l = 1, 2, \ldots, r\), the Krasulina-type stochastic approximation process \((X_n^l)\) of the general factor \(\theta_l\) in \(\mathbb{R}^{p*}\) (Krasulina, 1970, Bouamaine and Monnez, 1998):
\[
X_{n+1}^l = \text{orth}_{M_n}(Y_{n+1}^l)
\]
\[
Y_{n+1}^l = X_n^l + a_n \left( B_n - F_n(X_n^l)I \right) X_n^l
\]
\[
F_n(X_n^l) = \frac{\langle B_n X_n^l, X_n^l \rangle_{n-1}}{\|X_n^l\|_{n-1}^2};
\]

\(X_{n+1}^l = \text{orth}_{M_n}(Y_{n+1}^l)\) means that \((X_{n+1}^1, \ldots, X_{n+1}^l)\) is obtained by a Gram-Schmidt orthogonalization with respect to \(M_n\) of \((Y_{n+1}^1, \ldots, Y_{n+1}^l)\).
4.2 Principle of the study of convergence

The details of the proof of convergence of this type of process are given by Bouamaine and Monnez (1998).

Denote $\wedge$ the exterior product of elements of $\mathbb{R}^{p^*}$ and for $j = 1, \ldots, p$, $j \wedge \mathbb{R}^{p^*}$ the exterior algebra of order $j$ of $\mathbb{R}^{p^*}$: $(e_1, \ldots, e_p)$ being a basis of $\mathbb{R}^{p^*}$, the set of $C_j^p$ exterior products $e_{i_1} \wedge \ldots \wedge e_{i_j}$ with $1 \leq i_1 < \ldots < i_j \leq p$ is a basis of $j \wedge \mathbb{R}^{p^*}$.

Define the inner product in $j \wedge \mathbb{R}^{p^*}$ derived from that in $\mathbb{R}^{p^*}$ defined by $M^{-1}$; in this definition $G_j$ is the set of permutations of $\{k_1, \ldots, k_j\}$, $s(\sigma)$ is the number of inversions in the permutation $\sigma$ and $\varepsilon(\sigma) = (-1)^{s(\sigma)}$:

$$\langle e_{i_1} \wedge \ldots \wedge e_{i_j}, e_{k_1} \wedge \ldots \wedge e_{k_j} \rangle = \sum_{\sigma \in G_j} \varepsilon(\sigma) \langle e_{i_1}, e_{\sigma(k_1)} \rangle_{M^{-1}} \ldots \langle e_{i_j}, e_{\sigma(k_j)} \rangle_{M^{-1}}.$$

Suppose that the $r$ greatest eigenvalues of the endomorphism $B = MC$ in $\mathbb{R}^{p^*}$ are different: $\lambda_1 > \ldots > \lambda_r$. Define for $j = 1, \ldots, r$, the endomorphism $j^1 B$ in $j \wedge \mathbb{R}^{p^*}$ by:

$$j^1 B(x^1 \wedge \ldots \wedge x^j) = \sum_{h=1}^{j} x^1 \wedge \ldots \wedge Bx^h \wedge \ldots \wedge x^j, x^l \in \mathbb{R}^{p^*}, l = 1, \ldots, j.$$

If $V^1, \ldots, V^j$ are eigenvectors of $B$ corresponding respectively to $\lambda_1, \ldots, \lambda_j$, $V^1 \wedge \ldots \wedge V^j$ is eigenvector of $j^1 B$ corresponding to the greatest eigenvalue $\lambda_{1j} = \sum_{l=1}^{j} \lambda_l$. Denote $jS_1$ the eigensubspace corresponding to $\lambda_{1j}$ and $(jS_1)^\perp$ its orthogonal.

The proof of convergence is made in two steps. Denote $jX_n = X^1_n \wedge \ldots \wedge X^j_n$. It is proved first that for $j = 1, \ldots, r$, $\frac{jX_n}{\|jX_n\|}$ converges a.s. in a set $jE$ to $V^1 \wedge \ldots \wedge V^j \in jS_1$. 

It is proved then that, for \( l = 1, \ldots, r \), \( \|X_k^l\| \) converges a.s. in \( \cap_{j=1}^l jE \) to \( V^l \). The definition of the convergence set \( jE \) is as follows.

In the deterministic case \( B_n = B, \ M_n = M^{-1} \), define

\[
h_j(jx) = \frac{\langle j^1B^jx, jx \rangle}{\langle jx, jx \rangle}, \ jx \in j\cap \mathbb{R}^p; \]

and the process \((jU_n)\) in \( j\cap \mathbb{R}^p \) by

\[
j_{n+1} = (I + a_n (j^1B - h_j(jU_n)) ) jU_n.
\]

In this case \( jE \) is the set \( \{ jX_1 \notin (j^1S_1) \} \); \( X_1^1, \ldots, X_1^j \) may not be orthogonal to the subspace generated by the eigenvectors of \( B \) corresponding to its \( j \) greatest eigenvalues.

The process \((jX_n) = (X_n^1 \cap \ldots \cap X_n^j)\) can be considered as resulting from a stochastic perturbation of \((jU_n)\); denote

\[
\Delta_{nj} = 1 + a_n (\lambda_{1j} - h_j(jX_n))
\]

\[
Q^j = jX_1 + \sum_{n=1}^\infty \frac{jX_{n+1} - (I + a_n (j^1B - h_j(jX_n)) ) jX_n}{\prod_{i=1}^n \Delta_{ij}}.
\]

Then \( jE = \{ Q^j \notin (j^1S_1) \} \). Remark that \( Q^j = jX_1 \) in the case of the process \((jU_n)\).

4.3 Convergence of the process

Suppose:

\[(H1') \text{ There is no affine relation between the components of } Z.\]
(H2’) Z has 4th order moments.

(H3”) \( (a_n = \frac{a}{n^2}, a > 0, \frac{2}{3} < \alpha < 1) \) or \( (a_n = \frac{a}{n}, a > \frac{1}{2 \min \lambda_{\min} E[Z_1^i Z_1^j]}, Z_i = \left( \begin{array}{c} Z_i^1 \\ 1 \end{array} \right) ) \).

**Theorem 4** Assume \( H1', H2', H3'' \); then, for \( l = 1, \ldots, r \), \( Q^l \) converges a.s. Suppose moreover that the \( r \) greatest eigenvalues of \( B \) are different; then, for \( l = 1, \ldots, r \), \( X_n^l \) converges a.s. in \( \cap_{j=1}^l E \) to a random eigenvector of \( B \) corresponding to its \( l \)th greatest eigenvalue.

**Proof.** The convergence of this type of process is proved in theorem 4 of Bouamaine and Monnez (1998, p. 24) under the following assumptions:

1. \( \sum_{1}^{\infty} a_n \|B_n - B\| < \infty \) a.s.
2. \( M_n \rightarrow M^{-1}, \sum_{1}^{\infty} a_n \|M_{n-1} - M^{-1}\| < \infty \) a.s.
3. \( a_n > 0, \sum_{1}^{\infty} a_n = \infty, \sum_{1}^{\infty} a_n^2 < \infty \).

It suffices to verify (1) and (2).

By \( H1', H2', H3'' \) and theorem 3, \( \sum_{n=1}^{\infty} a_n \|B_n^{ij} - B^{ij}\| < \infty \) a.s. for every pair \((i, j)\); then (1) is verified. For \( k = 1, \ldots, q \):

\[
\|M_{n-1}^{k} - C^{k}\| \leq \left\| \frac{1}{n-1} \sum_{i=1}^{n-1} Z_i^k Z_i^{k'} - E[Z^k Z^{k'}] \right\| + \left\| \frac{Z_k}{n} - E[Z^k] \right\| + \left\| E[Z^k] \right\| \]

\[
\frac{Z_k}{n} \rightarrow E[Z^k] \text{ a.s.}; \sum_{n=1}^{\infty} a_n E\left[\left\| \frac{Z_k}{n} - E[Z^k] \right\| \right] = \sum_{n=1}^{\infty} a_n O\left( \frac{1}{\sqrt{n}} \right) < \infty.
\]

Then: \( \sum_{n=1}^{\infty} a_n \|M_{n-1}^{k} - C^{k}\| < \infty \) for \( k = 1, \ldots, q \), \( \sum_{n=1}^{\infty} a_n \|M_{n-1} - M^{-1}\| < \infty \) a.s. (2) is verified. \( \blacksquare \)
