RÉSUMÉ.
ABSTRACT. In this paper is presented a finite volume (DDFV) scheme for solving elliptic equations with heterogeneous anisotropic conductivity tensor. That method is based on the definition of a discrete divergence and a discrete gradient operator. These discrete operators have close relationships with the continuous ones, in particular they fulfil a duality property related with the Green formula. The operators are defined in dimension 2 and 3, their duality property is stated and used to establish the well posedness of the approximation scheme as well as its symmetry/positiveness. In the last part, the method is used for the resolution of a problem arising in bio-mathematics: the ECG (electrocardiogram) simulation. This is done on a 2D slice of a realistic torso defined from segmented MRI medical images.

1. Introduction

The aim of this paper is to define a finite volume discretisation (called DDFV discretisation) for the following elliptic equation on a bounded domain $\Omega \subset \mathbb{R}^d$, $d = 2, 3$. For a conductivity tensor $G = G(x)$ (symmetric positive definite and uniformly elliptic on $\Omega$) that is anisotropic and also heterogeneous, and for a mixed Neumann/Dirichlet homogeneous boundary condition on $\partial \Omega = \partial \Omega^N \cup \partial \Omega^D$, we search $\varphi$ such that ($n$ is a unit normal on the boundary):

$$\text{div}(G \nabla \varphi) = f, \quad G \nabla \varphi \cdot n = 0 \text{ on } \partial \Omega^N, \quad \varphi|_{\partial \Omega^D} = 0 \text{ on } \partial \Omega^D, \quad f \in L^2(\Omega). \quad (1)$$

Precisely, one assumes that there exists one (or more) crack $\Gamma$ in the domain that splits $\Omega$ in $\Omega_1$, $\Omega_2$ and such that $G$ has a discontinuity across $\Gamma$. One thus imposes the transmission condition ($n$ is a normal to $\Gamma$), in the trace sense on $\Gamma$:

$$\varphi|_{\Omega_1} = \varphi|_{\Omega_2}, \quad G|_{\Omega_1} \nabla \varphi|_{\Omega_1} \cdot n = G|_{\Omega_2} \nabla \varphi|_{\Omega_2} \cdot n \text{ on } \Gamma. \quad (2)$$

When $G|_{\Omega_i}$ is smooth enough, the classical theory (see e.g. [LAD 68]) tells us that (1) has a unique variational solution $\varphi \in H^1(\Omega)$ such that $\varphi|_{\Omega_i} \in H^2(\Omega_i)$ and such that the boundary condition in (1) and the transmission conditions in (2) hold in the trace sense. Whenever $\partial \Omega^N = \partial \Omega$, uniqueness doesn’t hold anymore and there is then a solution iff $f$ has zero mean value, all solution then differ up to a constant.

2. DDFV discretisation of the problem

2.1. Mesh definition and discrete data

We consider a Delaunay triangulation/tetrahedrisation $\mathcal{C}$ of a bounded polygonal/polyhedral subset $\Omega \subset \mathbb{R}^d$, $d = 2, 3$. We denote by $\mathcal{V}$ and $\mathcal{I}$ the associated sets of vertices and interfaces (elements edges/faces). The elements $C \in \mathcal{C}$ will be called primal cells. For equation (1) to be correctly discretised, we naturally assume that the internal interfaces "follow" cracks in $G$ and that the boundary interfaces $\sigma \subset \partial \Omega$ are dealt into two subsets $\mathcal{I}^D$, $\mathcal{I}^N$ such that $\Omega^N = \cup_{\sigma \in \mathcal{I}^N} \sigma$, $\Omega^D = \cup_{\sigma \in \mathcal{I}^D} \sigma$. The set of vertices of the interfaces $\sigma \in \mathcal{I}^D$ is denoted by $\mathcal{V}^D \subset \mathcal{V}$.

To every primal cell $C$ is associated a centre $K \in C$ (its iso-barycentre in practice). By $C_K$ one denotes the primal cell $C$ of centre $K$. To any interface $\sigma \in \mathcal{I}$ is associated a centre $Y_\sigma \in \sigma$ (also its iso-barycentre in practice), also simply denoted $Y$. Every internal interface $\sigma \in \mathcal{I}$ is the boundary between two primal cells $C_1$ and $C_2$. This is denoted by $\sigma = C_1 \cap C_2$. For more simplicity one shall denote by the same symbol any geometrical element and its measure : if $\sigma \in \mathcal{I}$, $\sigma$ also denotes its length/area ; if $C \in \mathcal{C}$, $C$ also denotes its area/volume, $\Omega$ both denotes the domain and its measure...

To every vertex $A \in \mathcal{V}$ is associated a dual cell $P_A$. Let us first introduce the subset $\mathcal{I}_A \subset \mathcal{I}$ of all the interfaces having $A$ as a vertex. To every $\sigma \in \mathcal{I}_A$ is associated a geometrical element $P_{A,\sigma}$. $P_A$ is given by $P_A = \cup_{\sigma \in \mathcal{I}_A} P_{A,\sigma}$.

The elements $P_{A,\sigma}$ are defined as follows (see figure 2.1). Let $\sigma = C_{K_1} \cap C_{K_2}$ be an
internal interface and let $Y$ be $\sigma$’s centre. In dimension 2, $P_{A,\sigma}$ is the quadrilateral $AK_1YK_2$. In dimension 3, let $B$ and $C$ be the two other vertices of $\sigma$ ($\sigma = ABC$). Then $P_{A,\sigma}$ is the reunion of the two pyramids having the same quadrilateral base $ABYC$ and $K_1, K_2$ for apex : $P_{A,\sigma} = ABYC K_1 \cup ABYC K_2$. That definition has obvious extension to the case $\sigma \subset \partial \Omega$.

Remark that in dimension 2 the (interiors of the) dual cells are disjoints and recover the whole domain, therefore $\sum_{A \in V} P_A = \Omega$. Whereas in dimension 3 the dual cells are no more disjoints, if $A$ and $B$ are two vertices of the same interface $\sigma$, $P_{A,\sigma} \cap P_{B,\sigma} \neq \emptyset$. Actually the dual cells now recover exactly twice the whole domain, so that $\sum_{A \in V} P_A = 2\Omega$.

To every interface $\sigma \in \mathcal{I}$ is associated one diamond cell $D_{\sigma}$. For an internal interface $\sigma = CK|CL$, it is defined as $D_{\sigma} = D_{\sigma,K} \cup D_{\sigma,L}$ where $D_{\sigma,K}$, $D_{\sigma,L}$ are the two triangles/pyramids with base $\sigma$ and apex $K$ and $L$ respectively, as depicted on figure 2.1. In the case of a boundary interface $\sigma \subset \partial \Omega$, $D_{\sigma}$ is a simple triangle/pyramid, $D_{\sigma} = D_{\sigma,K}$. The $D_{\sigma,K}$ will be called sub-diamond cells.

To this different types of cells are associated the following types of data : A discrete vector field $X_h$ (resp. discrete tensor $G_h$) is a vector (resp. matrix) function, piecewise constant on each sub-diamond cell $D_{\sigma,K}$. To each internal interface $\sigma = CK|CL$, it is associated two vectors $X_{\sigma,K}$ and $X_{\sigma,L}$ (resp. matrices $G_{\sigma,K}$ and $G_{\sigma,L}$) on each side of $\sigma$. $G_{\sigma,K}$ is always assumed symmetric positive definite. We shall say that $X_h$ is conservative relatively to $G_h$ if ($n_\sigma$ being a normal to $\sigma$) :

$$\forall \sigma \in \mathcal{I} \text{ such that } \sigma = CK|CL : \ G_{\sigma,K} X_{\sigma,K} \cdot n_\sigma = G_{\sigma,L} X_{\sigma,L} \cdot n_\sigma \ , \ (3)$$

A discrete scalar $\varphi_h$ is the data of two sets of scalars $(\varphi_A)_{A \in V}$, $(\varphi_K)_{K \in \mathcal{C}}$ associated to the vertices and primal cells centres respectively. A DDFV function is a scalar function $\tilde{\varphi}_h$, piecewise affine on $AY\sigma K$ (resp. $ABY\sigma K$) whenever $\sigma \in \mathcal{I}$, $A \in V$ (resp. $A, B \in V$) is (are) vertex(es) of $\sigma$ in dimension 2 (resp. 3) and $\sigma \subset CK$, $CK \in \mathcal{C}$.
2.2. The discrete operators and the problem discretisation

The discrete divergence $\text{div}_h$ of a discrete vector field $X_h$ is the discrete scalar:

$$ (\text{div}_h X_h)_A = \frac{1}{P_A} \int_{\partial P_A} X_h \cdot n_{\partial P_A} \, ds, \quad (\text{div}_h X_h)_K = \frac{1}{C_K} \int_{\partial C_K} X_h \cdot n_{\partial C_K} \, ds, \quad (4) $$

where $n_{\partial E}$ is the outward unit normal on the boundary of the polygonal/polyhedral element $E$. That definition makes sense because there are no discontinuities of $X_h$ on the edges/faces of primal and dual cells.

The discrete gradient of a DDFV function $\tilde{\varphi}_h$ is the discrete vector field:

$$ (\nabla_h \tilde{\varphi}_h)_{\sigma,K} = \frac{1}{D_{\sigma,K}} \int_{D_{\sigma,K}} \nabla \varphi_h \, dx. \quad (5) $$

The discrete gradient for a discrete scalar is defined below, for implementation, a practical formulation is given in appendix A.

**Definition 2.1.** Let us consider a discrete scalar $\varphi_h$ such that $\varphi_A = 0$ for all $A \in V_D$ and a discrete tensor $G_h$. Then there exists a unique DDFV function $\tilde{\varphi}_h$ such that:

$$ \forall A \in V : \tilde{\varphi}_h(A) = \varphi_A, \quad \forall C_K \in C : \tilde{\varphi}_h(K) = \varphi_K, $$

$$ \forall \sigma \in \mathcal{I}_N : \tilde{\varphi}_h(Y_\sigma) = 0, \quad \forall \sigma \in \mathcal{I}_N : G_\sigma (\nabla_h \tilde{\varphi}_h)_\sigma \cdot n_\sigma = 0, $$

and such that $\nabla_h \tilde{\varphi}_h$ is conservative relatively to $G_h$, as defined in (3).

Relatively to $G_h$, the discrete gradient of $\varphi_h$ is defined as $\nabla_h \varphi_h = \nabla_h \tilde{\varphi}_h$.

The previously defined discrete operators fulfil a duality property called discrete Green formula by analogy with the continuous case:

**Proposition 2.2.** Let $G_h$, a discrete tensor, $\varphi_h$, a discrete scalar and consider the DDFV function $\tilde{\varphi}_h$ associated to $\varphi_h$ relatively to $G_h$. If $X_h$ is a discrete vector field that satisfy $X_{\sigma,K} \cdot n_\sigma = X_{\sigma,L} \cdot n_\sigma$ on every internal interface $\sigma = C_K|C_L$, then:

$$ \int_{\Omega} (\nabla_h \tilde{\varphi}_h) \cdot X_h \, dx = - \frac{1}{d} \sum_{C_K \in C} \varphi_K (\text{div}_h X_h)_K C_K - \frac{1}{d} \sum_{A \in V} \varphi_A (\text{div}_h X_h)_A P_A $$

$$ + \int_{\partial \Omega} \tilde{\varphi}_h(n_{\partial \Omega}) X_h \cdot n_{\partial \Omega} \, ds \quad (6) $$

The consequence is the following:

**Proposition 2.3.** The right hand side $f$ in (1) being discretised in some discrete scalar $f_h$, we look for a discrete scalar $\varphi_h$ such that:

$$ \forall A \in V^D : \varphi_A = 0, \quad \forall \sigma \in \mathcal{I}_N : G_\sigma (\nabla_h \varphi_h)_\sigma \cdot n_\sigma = 0, \quad (7) $$

$$ \forall A \in V - V^D : (\text{div}_h (G_h \nabla_h \varphi_h))_A = f_A, \quad \forall C_K \in C : (\text{div}_h (G_h \nabla_h \varphi_h))_K = f_K $$

Such a $\varphi_h$ satisfies the transmission conditions (2) in a discrete sense by construction. If $I^D \neq \emptyset$, (7) has a unique solution. The resulting numerical linear problem to invert is moreover symmetric positive definite. The Neumann problem ($I^D = \emptyset$) has a solution iff $\frac{1}{d} \sum_{C_K \in C} f_K C_K + \frac{d-1}{d} \sum_{A \in V} f_A P_A = 0$. The linear problem to invert is now symmetric positive, its kernel is composed of the discrete scalar $\psi_h$ such that $\psi_A = C_1, \psi_K = C_2$.

3. Application

The bidomain model (see e.g. [KEE 98]) describes the electrical activity of the heart. It involves two compartments: the intra-extra cellular mediums, and models a trans-membrane potential $v = \varphi_i - \varphi$, difference between the intra-extra cellular potentials respectively. We use here the modified monodomain model (see [CLE 04]), $v(x,t)$ is given through a reaction diffusion system involving a second variable $w(x,t) \in \mathbb{R}^N$ that describes the cells membrane activity ($N$ is up to 20). It is used to simulate the normal propagation of excitation potential wave fronts ($v$ passing from a rest value to a plateau value) and de-excitation, see figure 3. It reads:

$$A_m C_m \frac{\partial v}{\partial t} + A_m I_{ion}(v, w) = \text{div}(G_1 \nabla v) + I_{app}(x,t), \quad \frac{\partial m}{\partial t} = g(v, w). \quad (8)$$

$A_m, C_m$ are constants, $G_1$ is a non constant anisotropy tensor described below, $I_{ion}$, $g$ are reaction terms and $I_{app}$ a source term (applied current) that activates the system. The electrocardiograms (ECG) is the body surface potential resulting from that cardiac electrical activity. It is the trace on the torso $T$ boundary $\partial T$ of the extracellular potential $\varphi$. In the extra cardiac $T - H$, $\varphi(x,t)$ is given by a Poisson equation $\text{div}(G_T \nabla \varphi) = 0$, where $G_T$ is isotropic heterogeneous between the different tissue layers conductivities (lungs, blood...). In the heart $H$, current balance between the intra and extra cellular compartments gives $\text{div}(G_2 \nabla \varphi) = -\text{div}(G_3 \nabla v)$. The tensors
Figure 3. Notations for the gradient definition. (a) Two dimensional case: interface \( \sigma = AB = C_K|C_L \) of centre \( Y \), the three vectors \( \mathbf{n}, \mathbf{m}_K, \mathbf{m}_L \) have unit length and are respectively orthogonal to \( \sigma, YK, YL \). Three dimensional case. (b) Interface \( \sigma = ABC = C_K|C_L \) of centre \( Y \), \( \mathbf{n} \) its unit normal from \( C_K \) towards \( C_L \). (c) Same interface \( \sigma \) view from above, all vectors have unit length, \( \mathbf{m}_{A,K}, \mathbf{m}_{B,K} \) and \( \mathbf{m}_{C,K} \) are orthogonal to \( AYK \), \( BYK \) and \( CYK \) respectively; same thing for \( \mathbf{m}_{A,L}, \mathbf{m}_{B,L} \) and \( \mathbf{m}_{C,L} \) by turning \( K \) into \( L \).

\( G_i \) take into account the fibrous organisation of the heart. They read the same anisotropic/non constant form: \( G_i(x) = P^{-1}(x)\tilde{G}_i P(x) \), where \( \tilde{G}_i = \text{Diag}(g_{li}^i, g_{ti}^i) \) is a reference matrix: \( g_{li}^i, g_{ti}^i \) being the longitudinal/transverse conductivities along/across the cardiac fibres. \( P(x) \) then is a change of basis matrix from the Frenet basis attached to the fibre direction at point \( x \). On the whole domain \( T \), this results in one global elliptic equation per time instant \( t \):

\[
\text{div}(G \nabla \varphi(t)) = f(v(t)) , \quad f(v(t)) = \begin{cases} 
0 & \text{in } H \\
-\text{div}(G_3 \nabla v(t)) & \text{in } T - H
\end{cases} , \quad (9)
\]

completed with the transmission conditions (2) on the heart/torso boundary and also on the interface between different tissue layers, and also with a Neumann boundary condition on \( \partial T \) (no current flow out of the body). In that problem, \( v(x, t) \) is an entry coming from a first computation on the heart previously described.

We then discretised (9) using the DDFV scheme. Our domain \( T \) is a torso slice mesh coming from MRI segmented data and counting 600 000 degrees of freedom. The domain is divided in four parts: the heart, the ventricles cavities (filled in with blood), the lungs and the remaining torso, each part having the different previously described conductivity properties. \( \varphi \) is computed on \( T \) at each \( ms \), the ECG body surface potential is recorded at 6 leads located on the torso boundary, see figure 3. On a whole cardiac cycle (\( \simeq 600 \text{ ms} \)), 600 computation are thus performed. That computation necessitates the inversion of an ill-conditioned symmetric positive linear system at each \( ms \). For this a Gm-Res solver combined with a basic SSOR preconditioning has been used.
A. Discrete gradient implementation

With the notations of def. 2.1 and of figure A, the expression of $\nabla_h \varphi_h$ is:

$$d = 2 : \quad 2D_{\sigma,K}(\nabla_h \varphi_h)_{\sigma,K} = (\tilde{\varphi}(Y) - \varphi_K) \sigma n + (\varphi_B - \varphi_A) K Y m_K$$

$$d = 3 : \quad 3D_{\sigma,K}(\nabla_h \varphi_h)_{\sigma,K} = (\tilde{\varphi}(Y) - \varphi_K) \sigma n + (\varphi_B - \varphi_C) A Y K m_{A,K}$$

$$+ (\varphi_C - \varphi_A) B Y K m_{B,K} + (\varphi_A - \varphi_B) C Y K m_{C,K}$$

It involves the DDFV function $\tilde{\varphi}_h$ in def. 2.1, whose definition is completed by:

$$d = 2 : \quad \tilde{\varphi}_h(Y) = \alpha \varphi_K + (1 - \alpha) \varphi_L + k(\varphi_B - \varphi_A)$$

$$d = 3 : \quad \tilde{\varphi}_h(Y) = \alpha \varphi_K + (1 - \alpha) \varphi_L + k_A(\varphi_B - \varphi_C) + k_B(\varphi_C - \varphi_A) + k_C(\varphi_A - \varphi_B)$$

with:

$$\alpha^{-1} = 1 + \frac{D_{\sigma,K} n G_{\sigma,L} n}{D_{\sigma,L} n G_{\sigma,K} n}$$

$$k = \frac{L Y}{\sigma} \frac{m_L G_{\sigma,L} n}{D_{\sigma,K}} n G_{\sigma,K} n + n G_{\sigma,L} n - \frac{K Y}{\sigma} \frac{m_K G_{\sigma,K} n}{D_{\sigma,L}} n G_{\sigma,L} n + n G_{\sigma,K} n$$

$$k_Z = \frac{Z Y L}{\sigma} \frac{m_Z L G_{\sigma,L} n}{D_{\sigma,K}} n G_{\sigma,K} n + n G_{\sigma,L} n - \frac{Z Y K}{\sigma} \frac{m_Z K G_{\sigma,K} n}{D_{\sigma,L}} n G_{\sigma,L} n + n G_{\sigma,K} n$$

For boundary interfaces this expression is adapted as follows. For $\sigma \in \mathcal{I}^D$, $\tilde{\varphi}_h(Y) = 0$. For $\sigma \in \mathcal{I}^N$, one suppresses $D_{\sigma,L}$ by stating $L = Y$ and $G_{\sigma,L} = 0$.
