Abstract

Following the Hodge decomposition of regular vector fields we can decompose the second member of any Liénard system into 2 (non unique) polynomials, first corresponding to potential and second to Hamiltonian dynamics. This polynomial Hodge decomposition is called potential-Hamiltonian, denoted PH-decomposition, and we give it for any polynomial differential system of dimension 2. We will give in a further Note an algorithm expliciting the PH-decomposition in the neighborhood of particular orbits like a limit-cycle for Liénard systems, the method being applicable for any polynomial differential system of dimension 2.

Résumé

Un système de Liénard est un système différentiel du second ordre, défini sur $\mathbb{R}^2$, du type : $dx/dt = y$, $dy/dt = -g(x) + yf(x)$ où g et f sont des polynômes. Un tel système est susceptible d'être décomposé, de manière non unique, en 2 parties polynomiales, l'une potentielle et l'autre hamiltonienne, c'est-à-dire qu'il existe deux polynômes P et H , définis sur $\mathbb{R}^2$ à valeurs dans $\mathbb{R}$, vérifiant $dx/dt = -\partial P/\partial x + \partial H/\partial y$, $dy/dt = -\partial P/\partial y - \partial H/\partial x$.

On montre, en utilisant la décomposition de Hodge des champs de vecteurs réguliers, que le second membre d'un tel système est décomposable en 2 polynômes, l'un correspondant à une dynamique de gradient et l'autre à une dynamique hamiltonienne. Cette décomposition de Hodge polynomiale est appelée potentielle-hamiltonienne, notée PH-décomposition, et nous en donnons la formule pour tout système différentiel polynomial du plan. Nous donnerons, dans une Note ultérieure, un algorithme permettant d'obtenir une formule explicite de la PH-décomposition au voisinage d'orbites particulières, telles qu'un cycle limite dans le cas des systèmes de Liénard, la méthode étant applicable à tout système différentiel polynomial du plan.

Version abrégée

Les systèmes de Liénard sont des Equations Différentielles Ordinaires de Dimension 2 (2D-EDO) du type : $dx/dt = y$, $dy/dt = -g(x) + yf(x)$, où f et g sont des polynômes.

Le système de van der Pol (cf. Figure 1) en est un bon exemple [2–4], utilisé pour modéliser de nombreux systèmes biologiques régulés, dont le système cardiaque. Les polynômes g et f d'un système de van der Pol

Email addresses: jacques.demongeot@imag.fr (Jacques DEMONGEOT), nicolas.glade@imag.fr (Nicolas GLADE), loic.forest@imag.fr (Loïc FOREST).

sont définis par : $g(x) = x$ et $f(x) = \mu(1 - x^2)$

L'unique cycle-limite d'un système de van der Pol, lorsqu'il existe, est une courbe non algébrique difficile à approximer et il peut être très utile, dans les applications, d'en avoir une estimation polynomiale. Nous proposons donc, de manière générale, une décomposition des EDO régulières, dite potentielle-hamiltonienne, dont l'existence est fondée théoriquement sur la décomposition de Hodge [5–8].

Une ODE est dite potentiel-hamiltonienne décomposable, s'il existe un couple de polynômes (P, H) , tel que: $dx/dt = -\partial P/\partial x + \partial H/\partial y$, $dy/dt = -\partial P/\partial y - \partial H/\partial x$

La partie du flot de vecteurs vitesse définie par P correspond à une dynamique de descente de plus fort gradient sur la surface représentative de P et la partie définie par H correspond à une dynamique sur les courbes de niveau de la surface représentative de H .

Un exemple de système hamiltonien pur classique est celui du système de Lotka-Volterra, utilisé pour modéliser les interactions proie/prédateur [9]. Des exemples de systèmes différentiels purs potentiels sont les systèmes de type n-switch, à second membre défini par une cinétique de Hill compétitive (équation 4), pour lesquels on peut obtenir explicitement la formule de définition de P et donc tracer la surface correspondante et en localiser les minima, qui sont les états stationnaires du n-switch (cf. Figure 3). Un exemple de système polynomial mixte potentiel-hamiltonien est le système chimique de Lotka, pour lequel il est facile d'exhiber P et H [22].

Pour généraliser la décomposition ci-dessus, on montre un théorème donnant une formule générale de décomposition potentielle-hamiltonienne (non unique), pour des ODE du type : $dx/dt = f(x, y)$, $dy/dt = g(x, y)$, où f et g sont des polynômes. A partir de cette formule générale, nous donnerons, dans deux prochaines notes, un algorithme permettant d'obtenir la décomposition potentielle-hamiltonienne dans le cas des systèmes de Liénard, puis de l'appliquer à des problèmes biologiques, dans lesquels il existe un grand intérêt à décomposer le flot en une partie potentielle (dont les paramètres sont responsables d'une modulation de fréquence d'un signal biologique, dans le cas d'une trajectoire du système de type cycle-limite) et une partie hamiltonienne (dont les paramètres sont responsables d'une modulation d'amplitude).

1. Introduction

Liénard systems [1] are 2-dimensional ordinary differential equations (2D ODEs) defined by $dx/dt = y$, $dy/dt = -g(x) + yf(x)$, where g and f are polynomials. The use of Liénard systems is universal in biological modeling, especially for physiological processes. A simple example of a Liénard system is given by the van der Pol system used to model the cardiac and respiratory rhythms [2–4], where :

$$g(x) = x, \quad f(x) = \mu(1 - x^2) \quad (1)$$

For $\mu > 0$, it presents a limit-cycle bifurcating from the stationary state located at the origin, which becomes progressively (as the anharmonic parameter μ increases) very far from a circle, and reciprocally becomes circular when μ tends to 0 (fig. 1).

Figure 1. – van der Pol system ($\mu = 1$, left) and μ tending to infinity in the upper phase plane (right)

For many applications, it is essential to approximate the limit-cycle (which is a non-algebraic closed curve of the plane) by a polynomial closed curve. A manner to do it is to decompose the second member of the van der Pol differential system into 2 polynomial parts, a potential one and a Hamiltonian one, contour lines of the Hamiltonian part being good candidates for estimating the limit-cycle.

2. Potential-Hamiltonian decomposition and Hodge decomposition

A 2D ODE $dx/dt = f(x, y)$, $dy/dt = g(x, y)$ is called potential-Hamiltonian decomposable (PH-decomposable), if and only if there is at least one couple of polynomials (P, H) such as:

$$dx/dt = -\partial P/\partial x + \partial H/\partial y, \quad dy/dt = -\partial P/\partial y - \partial H/\partial x \quad (2)$$

Figure 2. – Schematic representation of the gradient (potential P) flow (left) and of the conservative (Hamiltonian H) flow (right)

The potential flow is the projection on the 2D phase plane of a steepest descent velocity vector field on the surface defined by the potential P, and the Hamiltonian flow the vector field tangential to contour lines of the surface generated by H (fig. 2). The Hodge decomposition [5–8] ensures the existence of regular P and H functions (e.g. L^2 or C^1) for sufficiently smooth differential systems, e.g. ODEs having a second member of the same level of regularity L^2 or C^1 . We try here to obtain explicit expressions (if possible polynomials) for P and H . As example, we have the Lotka-Volterra system, a pure Hamiltonian system, introduced by V. Volterra to account for the fluctuations observed in the struggle for life between a prey population of size x and a predator population of size y [9]:

$$\begin{aligned} dx/dt &= x(a - by), & dX/dt &= \partial H/\partial Y \\ dy/dt &= y(cx - d), & dY/dt &= -\partial H/\partial X, \end{aligned} \quad \text{with } H(X, Y) = -ce^X + dX - be^Y + aY \quad (3)$$

by changing variables $X = \log(x)$ and $Y = \log(y)$ (population 'affinities'). The trajectories are just contour lines of H.

3. A pure potential system, the n-switch model

A n-switch model is used to formalize fully connected interaction networks with only inhibitory interactions. Such a system has been proposed in [10] to model genetic and metabolic regulations and is encountered in plant growth [11–13], embryogenesis [14, 15] and neural networks [16, 18], in which hormones (like auxine), proteins (like transduction peptide) or neuro-transmitters (like Gaba) secreted by a part of the system (e.g. apex in plants) inhibit the growth or activity of the other parts (e.g. cotyledonary buds in plants) (fig. 3). We can represent each inhibition by a Hill competition with a decay rate ν , constant entry coefficients α_i 's, a cooperativity coefficient c , a maximal reaction rate σ and affinity coefficients a_i 's as in the following system of equations, where x_i denotes the concentration (or the size, or the amount) of the component X_i in inhibitory interaction with all other components of the n-switch system [10]:

$$\forall i = 1..n, \quad \frac{dx_i}{dt} = -\nu x_i + \frac{\sigma a_i x_i^c}{1 + \sum_{j=1}^n a_j x_j^c} + \alpha_i \quad (4)$$

If we consider a n-switch with $c = 1$ and $\forall i = 1..n, \alpha_i = 0, a_i = 1$: $dx_i/dt = -\nu x_i + \sigma x_i/(1 + \sum_{j=1}^n x_j)$, with $\sigma > \nu$, then the non-zero stationary states have $m \geq 1$ components x_i^* equal to $(\sigma - \nu)/m\nu > 0$ and the others equal to 0. The Jacobian matrix in these stationary states has only one non-zero eigenvalue $\lambda = \nu(\nu - \sigma)/\sigma < 0$ and we need a complete stability analysis done in [10] in the general case. Studying the

stability basins topography is easier if we decompose the flow. By changing variables $y_i = (x_i)^{1/2}$ we see that the system is purely gradient with : $P(y) = \nu \sum_i y_i^2/4 - \sigma \log(1 + \sum_i a_i y_i^{2c})/4c - \sum_i \alpha_i \log y_i/2$ (cf. in fig. 3 a 2-switch with 3 stable stationary states). Replacing Hill competition by an allosteric inhibition, the system remains pure potential (cf. [19, 20] for a first proof of this result):

$$dx_i/dt = -\nu x_i + \sigma x_i((1+x_i)^{c-1} \prod_{j \neq i} (1+x_j)^c + a_i(1+a_i x_i)^{c-1} \prod_{j \neq i} (1+a_j x_j)^c) / (\prod_{k=1}^n (1+x_k)^c + \prod_{k=1}^n (1+a_k x_k)^c) + \alpha_i.$$

Hence, because $dy_i/dt = 1/(2y_i)dx_i/dt$, we have $dy_i/dt = -\partial P/\partial y_i$, with:

$$P(y) = \nu \sum_{i=1}^n y_i^2/4 - \sigma \log(\prod_{i=1}^n (1+y_i^2)^c + \prod_{i=1}^n (1+a_i y_i^2)^c)/4c - \sum_{i=1}^n \alpha_i \log y_i/2, \text{ where } y_i = (x_i)^{1/2}.$$

Figure 3. – Fully connected inhibitory interactions (except eventually auto-loops) of a n-switch (left) and potential P, if n=2 (right).

We represent on Figure 3 (right) the surface of the potential P for a 2-switch ($\nu = 1$, $c=2$, $\sigma = 2$, $a_i = 0.1$, $\alpha = 1$) over the square $[-5, 35] \times [-5, 35]$. The local minima are located in $(1.24, 24)$, $(24, 1.24)$, and $(12.35, 12.35)$ on the bissectrix.

4. Application to mixed potential-Hamiltonian systems, the Lotka and the Liénard equations

Chemical dynamical systems frequently offer equations susceptible to be PH-decomposed [21]. A historical example is the Lotka system [22] built to model a bi-reactant oscillatory reaction:

$$dx/dt = -xy - Kx - Ly, \quad dy/dt = xy + Ly \quad (5)$$

The decomposition is obtained by choosing

$$P(x, y) = (K + y)x^2/2 - Ly^2/2 - x^3/6 \text{ and } H(x, y) = -yx^2/2 - Ly^2/2 - x^3/6.$$

An other simple non-linear system is the Lorenz pendulum [23]:

$$dx/dt = y, \quad dy/dt = -ax - x^3 \quad (6)$$

This system is pure Hamiltonian with $H(x, y) = y^2/2 + ax^2/2 + x^4/4$. More generally, Liénard systems are PH-decomposable, if h and l are polynomials of order respectively m and p , and if $h^{(k)}$ denotes the k^{th} derivative of h , we have:

$$P(x, y) = \sum_{k=1}^n (-1)^k f^{(2k-2)} y^{2k} / (2k)! + \sum_{k=1}^m (-1)^k h^{(2k-2)} y^{2k-1} / (2k-1)! + \sum_{k=1}^p (-1)^k l^{(2k-2)} x^{2k-2} / (2k-2)!$$

$$H(x, y) = \int (g + h) + y^2/2 + \sum_{k=1}^n (-1)^k f^{(2k-1)} y^{2k+1} / (2k+1)! \\ + \sum_{k=1}^m (-1)^k h^{(2k-1)} y^{2k} / (2k)! + \sum_{k=1}^p (-1)^{k+1} l^{(2k-1)} x^{2k-1} / (2k-1)!$$

Proof is just the consequence of the following Proposition, Lemmas and Theorem, available for any 2D

ODE with sufficiently regular second member.

Proposition 1 Let's consider $V = f(x, y)\partial/\partial x + g(x, y)\partial/\partial y$ being a polynomial vector field, then there is a (non unique) PH-decomposition of V into two parts, a potential part, which is the gradient of a polynomial P and a conservative part, which is the Hamiltonian of a polynomial H such that: $V = -\text{grad}P + \text{ham}H$

Proof 1 Calculate $\text{div}V = D(x, y)$ and use complex coordinates $z = x + iy$, $\bar{z} = x - iy$. Then there is a (non unique) polynomial P such that $\partial^2 P / \partial z \partial \bar{z} = \partial^2 P / \partial x^2 + \partial^2 P / \partial y^2 = -D(x, y)$. The divergence $V + \text{grad}P$ equals 0. Hence this divergence is a Hamiltonian polynomial vector field deriving from a Hamiltonian function H : $V + \text{grad}P = (\partial H / \partial y, -\partial H / \partial x) = \text{ham}H$ ■

Lemma 1 Let's consider the 2D ODE : $dx/dt = 0$, $dy/dt = 0$ then its PH-decomposition can be any kernel of the type $P(x, y) = (f + ig)(x + iy) + (f - ig)(x - iy)$, $H(x, y) = -i(f + ig)(x + iy) + i(f - ig)(x - iy)$, f and g being differentiable functions.

Proof 2 It's sufficient to check that: $-\partial P / \partial x + \partial H / \partial y = 0$ and $-\partial P / \partial y - \partial H / \partial x = 0$ ■

Lemma 2 Let's consider the 2D ODE:

$$dx/dt = f_1(x, y) + f_2(x, y), \quad dy/dt = g_1(x, y) + g_2(x, y) \quad (7)$$

where the functions f_1, f_2, g_1, g_2 are infinitely differentiable and integrable. If $f^{[n](m)}(x, y)$ represents the function obtained from f by integrating n times in x and derivating m times in y then, for any integer $k \geq 4$, the potential P and the Hamiltonian H defined by :

$$\begin{aligned} P &= \sum_{j \leq k, j=4p+1} -f_1^{[j](j-1)} - g_1^{(j-1)[j]} + \sum_{j \leq k, j=4p+2} -f_2^{(j-1)[j]} - g_2^{[j](j-1)} + \\ &\quad \sum_{j \leq k, j=4p+3} f_1^{[j](j-1)} \pm g_1^{(j-1)[j]} + \sum_{j \leq k, j=4p+4} f_2^{(j-1)[j]} + g_2^{[j](j-1)} \\ H &= \sum_{j \leq k, j=4p+1} f_2^{(j-1)[j]} - g_2^{[j](j-1)} + \sum_{j \leq k, j=4p+2} f_1^{[j](j-1)} - g_1^{(j-1)[j]} + \\ &\quad \sum_{j \leq k, j=4p+3} -f_2^{(j-1)[j]} + g_2^{[j](j-1)} + \sum_{j \leq k, j=4p+4} -f_1^{[j](j-1)} + g_1^{(j-1)[j]} \end{aligned}$$

constitute the PH-decomposition of the following ODE's:

$$\begin{aligned} \text{for } k = 4p + 1, \quad dx/dt &= f_1 + f_2 + g_1^{(k)[k]} - g_2^{k}, \quad dy/dt = g_1 + g_2 + f_1^{k} - f_2^{(k)[k]} \\ \text{for } k = 4p + 2, \quad dx/dt &= f_1 + f_2 + f_1^{k} + f_2^{(k)[k]}, \quad dy/dt = g_1 + g_2 + g_1^{(k)[k]} + g_2^{k} \\ \text{for } k = 4p + 3, \quad dx/dt &= f_1 + f_2 - g_1^{(k)[k]} + g_2^{k}, \quad dy/dt = g_1 + g_2 - f_1^{k} + f_2^{(k)[k]} \\ \text{for } k = 4p + 4, \quad dx/dt &= f_1 + f_2 - f_1^{k} - f_2^{(k)[k]}, \quad dy/dt = g_1 + g_2 - g_1^{(k)[k]} - g_2^{k} \end{aligned}$$

If f_1, f_2, g_1, g_2 are polynomials of order less than n , then all these ODE's are equal to (7), since $k > n$.

Proof 3 It's sufficient to check that: $dx/dt = -\partial P / \partial x + \partial H / \partial y$, $dy/dt = -\partial P / \partial y - \partial H / \partial x$ and $f_1^{k} = f_2^{(k)[k]} = g_1^{(k)[k]} = g_2^{k} = 0$, $k > n$ ■

Theorem 1 Let's consider the 2D ODE: $dx/dt = f(x, y)$, $dy/dt = g(x, y)$ where f and g are polynomials: $f(x, y) = \sum_{i \geq j} a_{ij} x^i y^j + \sum_{i < j} c_{ij} x^i y^j$ and $g(x, y) = \sum_{i \geq j} b_{ij} x^i y^j + \sum_{i < j} d_{ij} x^i y^j$

Then the most general PH-decomposition is obtained by choosing

$$\begin{aligned} P &= \sum_{j \leq k, j=4p+1} -f_1^{[j](j-1)} - g_1^{(j-1)[j]} + \sum_{j \leq k, j=4p+2} -f_2^{(j-1)[j]} - g_2^{[j](j-1)} + \\ &\quad \sum_{j \leq k, j=4p+3} f_1^{[j](j-1)} + g_1^{(j-1)[j]} + \sum_{j \leq k, j=4p+4} f_2^{(j-1)[j]} + g_2^{[j](j-1)} + (f + ig)(x + iy) + (f - ig)(x - iy) \end{aligned}$$

$$H = \sum_{j \leq k, j=4p+1} f_2^{(j-1)[j]} - g_2^{[j](j-1)} + \sum_{j \leq k, j=4p+2} f_1^{[j](j-1)} - g_1^{(j-1)[j]} + \sum_{j \leq k, j=4p+3} -f_2^{(j-1)[j]} + g_2^{[j](j-1)} + \sum_{j \leq k, j=4p+4} -f_1^{[j](j-1)} + g_1^{(j-1)[j]} - i(f + ig)(x + iy) + i(f - ig)(x - iy)$$

where f, g are any differentiable functions and where:

$$f_1 = \sum_{i>j} a_{ij} x^i y^j + \frac{1}{2} \sum_{i=j} a_{ij} x^i y^j, \quad f_2 = \sum_{i<j} c_{ij} x^i y^j + \frac{1}{2} \sum_{i=j} a_{ij} x^i y^j$$

$$g_1 = \sum_{i>j} b_{ij} x^i y^j + \frac{1}{2} \sum_{i=j} b_{ij} x^i y^j, \quad g_2 = \sum_{i<j} d_{ij} x^i y^j + \frac{1}{2} \sum_{i=j} b_{ij} x^i y^j$$

Proof 4 The existence of a PH-decomposition is ensured by the above Proposition. Then to obtain P and H , it's sufficient to apply the above Lemmas 1 and 2 ■

5. Conclusion

In this article, we have shown the possibility to decompose any sufficiently regular 2D-differential system into two parts : a potential one having a dissipative gradient-like behaviour responsible, in general, for the amplitude of a periodic signal generated by the system, and another one, Hamiltonian, expressing the conservative part of the flow responsible for the frequency of this periodic signal. This decomposition, called PH-decomposition if the potential P and the Hamiltonian H are polynomials, is non unique, but we easily conceive that we can estimate the coefficients of P and H by obliging the dynamical flow to pass through certain known points on orbits of the studied system. Then we have obtained a way to algebraically estimate these orbits. The algorithm for doing this approximation (in particular in the case of limit-cycles) will be given in a further Note.
