Self-indexing energy function for Morse-Smale diffeomorphisms on 3-manifolds

V. Grines∗ F. Laudenbach† O. Pochinka‡

Abstract

The paper is devoted to finding conditions to the existence of a self-indexing energy function for Morse-Smale diffeomorphisms on a 3-manifold $M^3$. These conditions involve how the stable and unstable manifolds of saddle points are embedded in the ambient manifold. We also show that the existence of a self-indexing energy function is equivalent to the existence of a Heegaard splitting of $M^3$ of a special type with respect to the considered diffeomorphism.

Mathematics Subject Classification: 37B25, 37D15, 57M30.
Keywords: Morse-Smale diffeomorphism, Morse-Lyapunov function, Heegaard splitting.

Introduction

Let $M^n$ be a smooth closed orientable $n$-manifold. A diffeomorphism $f : M^n \to M^n$ is called a Morse-Smale diffeomorphism if its nonwandering set $\Omega(f)$ consists of finitely many hyperbolic periodic points ($\Omega(f) = \text{Per}(f)$) whose invariant manifolds have mutually transversal intersections. D. Pixton defined a Lyapunov function for a Morse-Smale diffeomorphism $f$ as a Morse function $\varphi : M^n \to \mathbb{R}$ such that $\varphi(f(x)) < \varphi(x)$ when $x$ is not a peri-

1A function $\varphi : M^n \to \mathbb{R}$ is called a Morse function if all its critical points are non-degenerate.
odic point and $\varphi(f(x)) = \varphi(x)$ when it is. Such a function can be constructed in different ways \footnote{In 1978 C. Conley \cite{Conley} proved the existence of a continuous Lyapunov function (that is a function which strictly decreases along orbits outside the chain recurrent set and is constant on components of the chain recurrent set) for any flow (or homeomorphism) given on a compact manifold. This fact was named later the Fundamental Theorem of dynamical systems (see, for example, \cite{Wiggins}, theorem 1.1, p. 404). Notice, that for Morse-Smale diffeomorphisms the chain recurrent set is exactly the non-wandering set and components of the chain recurrent set are the periodic orbits.} (see for instance \cite{Hirsch}).

If $\varphi$ is a Lyapunov function for a Morse-Smale diffeomorphism $f$, then any periodic point of $f$ is a critical point of $\varphi$ (see lemma \ref{lem:lyapunov-function}). The opposite is not true in general since a Lyapunov function may have critical points which are not periodic points of $f$. Then Pixton \cite{Pixton} defined an energy function for a Morse-Smale diffeomorphism $f$ as a Lyapunov function $\varphi$ such that the critical points of $\varphi$ coincide with the periodic points of $f$ and proved the following results.

- For any Morse-Smale diffeomorphism given on a surface there is an energy function.
- There is an example of a Morse-Smale diffeomorphism on $S^3$ which has no energy function.

If $p$ is a periodic point of period $k_p$ for the Morse-Smale diffeomorphism $f : M^n \to M^n$ then the stable manifold is $W^s(p) = \{ x \in M^n \mid f^{mk_p}(x) \to p \text{ when } m \to +\infty \}$; the unstable manifold is $W^u(p) = \{ x \in M^n \mid f^{mk_p}(x) \to p \text{ when } m \to -\infty \}$. The point $p$ is said to be a sink (resp. source) when $\dim W^u(p) = 0$ (resp. $\dim W^u(p) = n$). The point $p$ is called a saddle point when $\dim W^u(p) \neq 0, n$. A stable (resp. unstable) separatrix of the saddle point $p$ is a connected component of $W^s(p) \setminus p$ (resp. $W^u(p) \setminus p$).

Let us recall that a Morse-Smale diffeomorphism $f : M^n \to M^n$ is called gradient-like if for any pair of periodic points $x, y$ ($x \neq y$) the condition $W^u(x) \cap W^s(y) \neq \emptyset$ implies $\dim W^s(x) < \dim W^s(y)$. When $n = 3$, a Morse-Smale diffeomorphism is gradient-like if and only if the two-dimensional and one-dimensional invariant manifolds of its different saddle points do not intersect \footnote{Let us remark that the two-dimensional invariant manifolds of different saddle points of a gradient-like diffeomorphism may have a non empty intersection, namely along the so-called heteroclinic curves.}.

Let $f : M^n \to M^n$ be a gradient-like diffeomorphism. Then, it follows from \cite{Hirsch} (theorem 2.3), that the closure $\bar{\ell}$ of any one-dimensional unstable separatrix $\ell$ of a saddle point $\sigma$ is homeomorphic to a segment which consists of this separatrix and two points: $\sigma$ and some sink $\omega$. Moreover, $\bar{\ell}$ is everywhere smooth except, maybe, at $\omega$. So the topological embedding of $\bar{\ell}$ may be complicated in a neighborhood of the sink.
According to [1], \( \ell \) is called tame (or tamely embedded) if there is a homeomorphism \( \psi : W^s(\omega) \to \mathbb{R}^n \) such that \( \psi(\omega) = O \), where \( O \) is the origin and \( \psi(\ell \setminus \sigma) \) is a ray starting from \( O \). In the opposite case \( \ell \) is called wild.

In the above mentioned Pixton’s example, the non-wandering set of \( f : S^3 \to S^3 \) consists of exactly four fixed points: one source \( \alpha \), two sinks \( \omega_1, \omega_2 \), one saddle \( \sigma \) whose one unstable separatrix \( \ell_1 \) is tamely embedded and the other \( \ell_2 \) is wildly embedded (see fig. 1). Later, the class \( G_4 \) of diffeomorphisms on \( S^3 \) with such a nonwandering set was considered in [2], where it was proved that, for every diffeomorphism \( f \in G_4 \), at least one separatrix \( \ell_1 \) is tame. It was also shown that the topological classification of diffeomorphisms from \( G_4 \) is reduced to the embedding classification of the separatrix \( \ell_2 \). Hence it follows that there exist infinitely many diffeomorphisms from \( G_4 \) which are not topologically conjugate.

According to Pixton, if the separatrix \( \ell_2 \) is wildly embedded, the Morse-Smale diffeomorphism \( f \in G_4 \) has no energy function. The present paper is devoted to finding conditions to the existence of a self-indexing energy function (in the sense of definition 1.2 below) for Morse-Smale diffeomorphisms on 3-manifolds.

The first and third authors thank grant RFBR No 08-01-00547 of the Russian Academy for partial financial support.

1 Formulation of the results

If \( \varphi \) is a Lyapunov function of a Morse-Smale diffeomorphism \( f : M^n \to M^n \) then any periodic point \( p \) is a maximum of the restriction of \( \varphi \) to the unstable
manifold $W^u(p)$ and a minimum of its restriction to the stable manifold $W^s(p)$ (see lemma 2.1). If these extremums are non-degenerate then the invariant manifolds of $p$ are transversal to all regular level sets of $\varphi$ in some neighborhood $U_p$ of $p$. This local property is useful for the construction of a (global) Lyapunov function. So we introduce the following definitions.

**Definition 1.1** A Lyapunov function $\varphi : M^n \to \mathbb{R}$ for a Morse-Smale diffeomorphism $f : M^n \to M^n$ is called a Morse-Lyapunov function if any periodic point $p$ is a non-degenerate maximum of the restriction of $\varphi$ to the unstable manifold $W^u(p)$ and a non-degenerate minimum of its restriction to the stable manifold $W^s(p)$.

**Theorem 1** Among the Lyapunov functions of a Morse-Smale diffeomorphism $f$ those which are Morse-Lyapunov form a residual set in the $C^\infty$-topology.

If $p$ is a critical point of a Morse function $\varphi : M^n \to \mathbb{R}$ then, according to the Morse lemma (see, for example, [13]), in some neighborhood $V(p)$ of $p$ there is a local coordinate system $x_1, \ldots, x_n$, named Morse coordinates, such that $x_j(p) = 0$ for each $j = 1, n$ and $\varphi$ reads $\varphi(x) = \varphi(p) - x_1^2 - \ldots - x_q^2 + x_{q+1}^2 + \ldots + x_n^2$, where $q$ is the index $\varphi$ at $p$. It is convenient to deal with self-indexing Morse function for which $\varphi(p) = q$.

If $\varphi$ is a Lyapunov function for a Morse-Smale diffeomorphism $f : M^n \to M^n$ then $q = \dim W^u(p)$ for any periodic point $p$ of $f$ (see [13], lemma on p. 168). The next definition follows from S. Smale [19] who introduced a similar one for gradient-like vector fields.

**Definition 1.2** A Morse-Lyapunov function $\varphi$ is called a self-indexing energy function when the following conditions are fulfilled:

1) the set of the critical points of function $\varphi$ coincides with the set $\text{Per}(f)$ of the periodic points of $f$;
2) $\varphi(p) = \dim W^u(p)$ for any periodic point $p \in \text{Per}(f)$.

Sometimes we shall speak of a self-indexing energy function even when it is only defined on some domain $N \subset M^n$, meaning that the above conditions hold only for points $x \in N$ such that $f(x) \in N$. In the next results we only deal with 3-dimensional manifolds.

Let $f : M^3 \to M^3$ be a gradient-like diffeomorphism, $\omega$ be a sink of $f$ and $L(\omega)$ be the union of all unstable one-dimensional separatrices of saddles which contain $\omega$ in their closure. The collection $L(\omega)$ is tame if there is a homeomorphism $\varphi : W^s(\omega) \to \mathbb{R}^3$ such that $\varphi(\omega) = O$, where $O$ is the origin.

4The number of negative eigenvalues of the matrix $\frac{\partial^2 \varphi}{\partial x_i \partial x_j}(p)$ is called the index of the critical point $p$. 
and $\varphi(\ell \setminus \sigma)$ is a ray starting from $O$ for any separatrix $\ell \in L(\omega)$. In the opposite case the set $L(\omega)$ is wild. Notice that the tameness of each separatrix $\ell \in L(\omega)$ does not imply the tame property of $L(\omega)$. In [7] there is an example of a wild collection of arcs in $\mathbb{R}^3$ where each arc is tame. Using this example and methods of realization of Morse-Smale diffeomorphisms suggested in [2] and [3], it is possible to construct a gradient-like diffeomorphisms on $S^3$ having a wild bundle $L(\omega)$.

If $L(\omega)$ consists of exactly one separatrix $\ell$ then the tame property is equivalent to the existence of a smooth 3-ball $B_\omega \subset W^s(\omega)$ such that $\ell \cap \partial B_\omega$ consists of exactly one point (it follows from a criterion in [9]). Thus we give the following definition.

**Definition 1.3** We say that $L(\omega)$ is almost tamely embedded in $M^3$ if there is a smooth closed 3-ball $B_\omega \subset W^s(\omega)$ with $\omega \in \text{int} B_\omega$ such that $\ell \cap \partial B_\omega$ consists of exactly one point for each separatrix $\ell \in L(\omega)$.

We would like to understand what conditions could be added to the almost tame embedding property to obtain sufficient conditions for the existence of a self-indexing energy function.

Let $f : M^3 \to M^3$ be a Morse-Smale diffeomorphism. Let us denote by $\Omega^+$ (resp. $\Omega^-$) the set of all sinks (resp. sources), by $\Sigma^+$ (resp. $\Sigma^-$) the set of all saddle points having one-dimensional unstable (resp. stable) invariant manifolds, by $L^+$ (resp. $L^-$) the union of the unstable (resp. stable) one-dimensional separatrices. We set $A(f) = \Omega^+ \cup L^+ \cup \Sigma^+$, $R(f) = \Omega^- \cup L^- \cup \Sigma^-$ and $L = L^- \cup L^+$. By construction, $A(f)$ (resp. $R(f)$) is a connected set which is an attractor (resp. a repeller) of $f$. We set

$$g(f) = \frac{|\Sigma^+ \cup \Sigma^-| - |\Omega^+ \cup \Omega^-| + 2}{2},$$

where $|.|$ stands for the cardinality.

We will denote by $\mathcal{H}$ the set of Morse-Smale diffeomorphisms $f : M^3 \to M^3$ with the following properties:

1) $f$ is gradient-like;

5A compact set $A \subset M^n$ is an attractor of a diffeomorphism $f : M^n \to M^n$ if there is a neighborhood $V$ of the set $A$ such that $f(V) \subset V$ and $A = \bigcap_{n \in \mathbb{N}} f^n(V)$. A set $R \subset M^n$ is called a repeller of $f$ if it is an attractor of $f^{-1}$. 

5
2) the set $L$ of one-dimensional separatrices of $f$ is almost tamely embedded in $M^3$;
3) $M^3 \setminus (\mathcal{A}(f) \cup \mathcal{R}(f))$ is diffeomorphic to $S_{g(f)} \times \mathbb{R}$ where $S_{g(f)}$ is an orientable surface of genus $g(f)$.

**Theorem 3** If a Morse-Smale diffeomorphism $f : M^3 \to M^3$ belongs to $\mathcal{H}$ then it has a self-indexing energy function.

It follows from [8] that if the set of one-dimensional separatrices is tamely embedded (that is, $L(\omega)$ and $L(\alpha)$ are tame for each sink $\omega$ and source $\alpha$) then $M^3 \setminus (\mathcal{A}(f) \cup \mathcal{R}(f))$ is diffeomorphic to $S_{g(f)} \times \mathbb{R}$ and $M^3$ admits a Heegaard splitting of genus $g(f)$. Thus we get the next result.

**Corollary 1.4** If the set $L$ of one-dimensional separatrices of a gradient-like diffeomorphism $f : M^3 \to M^3$ is tamely embedded, then $f$ has a self-indexing energy function.

The next theorem gives necessary and sufficient conditions to the existence of a self-indexing energy function by means of special Heegaard splittings of $M^3$. We also need the following definition.

**Definition 1.5** Let $D$ be a subset of $M^n$. It is said to be $f$-compressed when $f(D)$ is contained in the interior of $D$.

**Theorem 4** A gradient-like diffeomorphism $f : M^3 \to M^3$ has a self-indexing energy function if and only if $M^3$ is the union of three domains with mutually disjoint interiors, $M^3 = P^+ \cup N \cup P^-$, satisfying the following conditions.

1) $P^+$ (resp. $P^-$) is a $f$-compressed (resp. $f^{-1}$-compressed) handlebody of genus $g(f)$ and $\mathcal{A}(f) \subset P^+$ (resp. $\mathcal{R}(f) \subset P^-$);
2) $W^s(\sigma^+) \cap P^+$ (resp. $W^u(\sigma^-) \cap P^-$) consists of exactly one two-dimensional closed disk for each saddle point $\sigma^+ \in \Sigma^+$ (resp. $\sigma^- \in \Sigma^-$);
3) there is a diffeomorphism $q : S_{g(f)} \times [0,1] \to N$ such that $q(S_{g(f)} \times \{t\})$, $t \in [0,1]$ bounds an $f$-compressed handlebody.

**Remark 1.6** Observe that condition 2) implies that the 1-dimensional separatrices are almost tamely embedded. Indeed, if thin neighborhoods of the disks $P^+ \cap W^s(\sigma^+)$, $\sigma^+ \in \Sigma^+$, are removed from $P^+$, one gets a union of balls whose boundaries fulfill definition 1.3.

---

6 Notice that items 1) and 2) do not imply item 3). In section 3 there is an example of a gradient-like diffeomorphism on $M^3 = S^2 \times S^1$ whose set of one-dimensional separatrices is almost tamely embedded and such that $M^3 \setminus (\mathcal{A}(f) \cup \mathcal{R}(f))$ is not a product.

7 Let us recall that a three-dimensional orientable manifold is called a handlebody of a genus $g \geq 0$ if it is obtained from a 3-ball by an orientation reversing identification of $g$ pairs of pairwise disjoint 2-discs in its boundary. The boundary of such a handlebody is an orientable surface of genus $g$. A Heegaard splitting of genus $g \geq 0$ for a manifold $M^3$ is a representation of $M^3$ as the gluing of two handlebodies of genus $g$ by means of some diffeomorphism of their boundaries. Their common boundary after gluing, a surface of genus $g$ in $M^3$, is called a Heegaard surface.
2 Properties of Lyapunov functions for a Morse-Smale diffeomorphism

Lemma 2.1 Let \( \varphi : M^n \to \mathbb{R} \) be a Lyapunov function for a Morse-Smale diffeomorphism \( f : M^n \to M^n \). Then

1) \(-\varphi \) is Lyapunov function for \( f^{-1} \);
2) if \( p \) is a periodic point of \( f \) then \( \varphi(x) < \varphi(p) \) for every \( x \in W^u(p) \setminus p \) and \( \varphi(x) > \varphi(p) \) for every \( x \in W^s(p) \setminus p \);
3) if \( p \) is a periodic point of \( f \) then \( p \) is a critical point of \( \varphi \).

Proof:

1) It follows from the definition that \( \varphi(x) \leq \varphi(f^{-1}(x)) \) for any \( x \) and the equality only holds for the periodic points. By multiplying this inequality by \(-1\) we get the wanted inequality.

2) As the unstable manifold of a periodic point \( p \) for \( f \) coincides with the stable manifold of \( p \) for \( f^{-1} \) it is enough to prove items 2) and 3) only for \( W^u(p) \).

Let \( x \in W^u(p) \setminus p \). It follows from the definition of the unstable manifold of a periodic point that \( \lim_{m \to \infty} f^{-mk_p}(x) = p \); hence \( \lim_{m \to \infty} \varphi(f^{-mk_p}(x)) = \varphi(p) \).

We have \( \varphi(x) < \varphi(f^{-k_p}(x)) < \ldots < \varphi(f^{-mk_p}(x)) < \ldots \) and, hence, \( \varphi(x) < \varphi(p) \).

3) Let us assume that \( p \) is a regular point of \( \varphi \). Thus the level set \( \varphi^{-1}(\varphi(p)) \) is \((n-1)\)-manifold. It follows from point 2) that \( T_p W^u(p) \) and \( T_p W^s(p) \) must be tangent to \( \varphi^{-1}(\varphi(p)) \). This is impossible because \( T_p W^u(p) \) and \( T_p W^s(p) \) generate \( T_p M^n \).

Denote \( Ox_1 \ldots x_q = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_{q+1} = \ldots = x_n = 0\} \) and \( Ox_{q+1} \ldots x_n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_1 = \ldots = x_q = 0\} \).

Lemma 2.2 Let \( f : M^n \to M^n \) be a Morse-Smale diffeomorphism and \( \mathcal{O}(p) \) be a periodic orbit of period \( k_p \) and \( \dim W^u(p) = q \). Then there exist a Morse-Lyapunov function \( \varphi_{\mathcal{O}(p)} \) defined on some neighborhood \( U_{\mathcal{O}(p)} \) of \( \mathcal{O}(p) \) and, for each \( r \in \mathcal{O}(p) \), Morse coordinates \( x_1, \ldots, x_n \) for \( \varphi_{\mathcal{O}(p)} \) near \( r \) such that:

1) \( \varphi_{\mathcal{O}(p)}(\mathcal{O}(p)) = q \);
2) \( (W^u(r) \cap U_{\mathcal{O}(p)}) \subset Ox_1 \ldots x_q \) and \( (W^s(r) \cap U_{\mathcal{O}(p)}) \subset Ox_{q+1} \ldots x_n \).

Proof: As \( \mathcal{O}(p) \) is a hyperbolic set then, for each \( r \in \mathcal{O}(p) \), there is a splitting of the tangent space \( T_r M^n \) as a direct sum \( T_r M^n = T_r W^u(r) \oplus T_r W^s(r) \) such that \( Df_r(T_r W^u(r)) = T_{f(r)} W^u(f(r)) \) and \( Df_r(T_r W^s(r)) = T_{f(r)} W^s(f(r)) \). Moreover, there is a metric \( \|\cdot\| \) on \( M^n \) such that for some \( \lambda, 0 < \lambda < 1 \), we have:

\[
\|Df^{-1}(v^u)\| \leq \lambda \|v^u\|, \\
\|Df(v^s)\| \leq \lambda \|v^s\|, 
\]
for each \( v^u \in E^u \) and \( v^s \in E^s \), where \( E^v = \bigcup_{r \in O(p)} T_r W^u(r) \) and \( E^s = \bigcup_{r \in O(p)} T_r W^s(r) \).

Let us define \( \varphi : E^u \oplus E^s \to \mathbb{R} \) by the formula

\[
\varphi(v^u, v^s) = q - \|v^u\|^2 + \|v^s\|^2.
\]

Let us check that \( \varphi(v^u, v^s) \) for all non-zero \( v^u \in E^u \) or \( v^s \in E^s \).

Indeed, \( \varphi(Df(v^u, v^s)) < \varphi(v^u, v^s) \) for all non-zero \( v^u \in E^u \) or \( v^s \in E^s \).

Among the Lyapunov functions of a Morse-Smale diffeomorphism \( f \), theorem 1 is the desired function.

Theorem 1: Among the Lyapunov functions of a Morse-Smale diffeomorphism \( f \) those which are Morse-Lyapunov form a residual set in the \( C^\infty \)-topology.

Proof: We recall that a property is said generic when it is shared by all points in a residual subset (i.e. a set which is a countable intersection of dense open subsets). Let us show that in the set of Lyapunov functions for \( f \), the set of Morse-Lyapunov functions for \( f \) is open and dense; hence, it is residual. Here, our property is clearly open. Let us show it is dense. Let us consider \( \varphi \), a Lyapunov function for the Morse-Smale diffeomorphism \( f \). In some open neighborhood \( U_{O(p)} \) of \( O(p) \) we have \( f(v^u, v^s) = Df(v^u, v^s) + o(v) \). Therefore \( \varphi(f(v^u, v^s)) < \varphi(v^u, v^s) \) for all non-zero \( (v^u, v^s) \in U_{O(p)} \) if this neighborhood is chosen small enough. Hence \( \varphi \) is the desired function.

\( \diamond \)

From lemma 2.2, we deduce the following genericity theorem.

\[ \text{Theorem 1} \quad \text{Among the Lyapunov functions of a Morse-Smale diffeomorphism } f \text{ those which are Morse-Lyapunov form a residual set in the } C^\infty \text{-topology.} \]

Proof: We recall that a property is said generic when it is shared by all points in a residual subset (i.e. a set which is a countable intersection of dense open subsets). Let us show that in the set of Lyapunov functions for \( f \), the set of Morse-Lyapunov functions for \( f \) is open and dense; hence, it is residual. Here, our property is clearly open. Let us show it is dense. Let us consider \( \varphi \), a Lyapunov function for the Morse-Smale diffeomorphism \( f \). In some open neighborhood \( U_{O(p)} \) of \( O(p) \) we have \( f(v^u, v^s) = Df(v^u, v^s) + o(v) \). Therefore \( \varphi(f(v^u, v^s)) < \varphi(v^u, v^s) \) for all non-zero \( (v^u, v^s) \in U_{O(p)} \) if this neighborhood is chosen small enough. Hence \( \varphi \) is the desired function.

\( \diamond \)

From lemma 2.2, we deduce the following genericity theorem.
non-degenerate maximum at \( p \). As \( T_pM^n \) is the direct sum of \( T_pW^u(p) \) and \( T_pW^s(p) \), then \( \varphi_c \) is non-degenerate at \( p \). Each point in \( \text{Per}(f) \) is a non-degenerate critical point of \( \varphi_c \), for any \( c > 0 \). Moreover, since the sum of two Lyapunov functions is a Lyapunov function, there is some open neighborhood \( \hat{U} \) of \( \text{Per}(f) \) on which \( \varphi_c \) is a Morse-Lyapunov function for any \( c > 0 \).

Besides, there is a positive \( \varepsilon \) such that, for every \( x \notin \hat{U} \cap f^{-1}(\hat{U}) \), one has \( \varphi(x) > \varphi(f(x)) + \varepsilon \). Thus, whatever \( \varphi_{\text{Per}(f)} \) is, there exists a small \( c \) so that \( \varphi_c \) fulfills the Lyapunov inequality for every \( x \notin \hat{U} \cap f^{-1}(\hat{U}) \). If \( \varphi_c \) is a Morse function then the proof is finished. If \( \varphi_c \) is not a Morse function then a last \( C^\infty \)-approximation of \( \varphi_c \), relatively to \( \hat{U} \), makes it a Morse-Lyapunov function everywhere.

\[\Box\]

3 Necessary conditions to the existence of a self-indexing energy function

**Theorem 2** If a Morse-Smale diffeomorphism \( f : M^3 \to M^3 \) has a self-indexing energy function then it is gradient-like and the set \( L \) of one-dimensional separatrices is almost tamely embedded.

To prove this theorem we need the two next lemmas.

**Lemma 3.1** If a Morse-Smale diffeomorphism \( f : M^n \to M^n \) has a self-indexing energy function \( \varphi \) then it is gradient-like.

**Proof:** Assume the contrary: a Morse-Smale diffeomorphism \( f : M^n \to M^n \) has a self-indexing energy function \( \varphi : M^n \to \mathbb{R} \) and it is not gradient-like. Then there are points \( x, y \in \text{Per}(f) \) \( (x \neq y) \) such that \( W^u(x) \cap W^s(y) \neq \emptyset \) and \( \dim W^s(x) \geq \dim W^s(y) \). Put \( \dim W^v(x) = k \), \( \dim W^v(y) = m \) and \( z \in W^u(x) \cap W^v(y) \). As \( n - k = \dim W^s(x) \geq \dim W^s(y) = n - m \) then \( k \leq m \). According to lemma 2.1, \( \varphi(z) < \varphi(x) = \dim W^u(x) = k \), \( \varphi(z) > \varphi(y) = \dim W^u(y) = m \), hence, \( k > m \). This is a contradiction. \(\Box\)

**Lemma 3.2** If a Morse-Smale diffeomorphism \( f : M^3 \to M^3 \) has a self-indexing energy function \( \varphi \) then the union of its one-dimensional separatrices are almost tamely embedded in \( M^3 \).

\[ Q_1(x) + c \cdot Q_2(x) > 0 \] for \( x \neq p \). It follows from reducibility of positive-definite quadratic form to sum of squares of all coordinates that \( Q_1(x) + c \cdot Q_2(x) \) is non-degenerate. Thus \( \varphi_c|_{W^u(p)} \) has non-degenerate minimum at the point \( p \).
Proof: We shall only give a proof for a sink. Let $\omega$ be a sink of period $k_\omega$, $L(\omega)$ be the union of all unstable one-dimensional separatrices whose closure contains $\omega$. According to lemma 3.1, $f$ is gradient-like and, hence, for any separatrix $\ell \in L(\omega)$ its closure $\bar{\ell}$ consists of $\ell \cup \{\omega, \sigma_\ell\}$, where $\sigma_\ell$ is a saddle point of $f$. As $\varphi$ is a Morse-Lyapunov function then in some neighborhood $U_\ell$ of $\sigma_\ell$ equipped with Morse coordinates we have $\varphi(x) = 1 - x_1^2 + x_2^2 + x_3^2$ and $W^u(\sigma_\ell)$ is transversal to the regular level sets of $\varphi$ in $U_\ell$. Let $U$ be the union of the $U_\ell$’s for $\ell \subset L(\omega)$.

Let $k$ be an integer so that $f^k$ leaves each $\ell$ invariant. Since the action of $f^k$ on $\ell$ is discrete it has a fundamental domain $[a_\ell, b_\ell] \subset U$, hence transversal to the level sets of $\varphi$. More precisely, $\varphi|_{[a_\ell, b_\ell]}$ has no critical points and $1 = \varphi(\sigma_\ell) > \varphi(a_\ell) > \varphi(b_\ell)$. We may choose all the $a_\ell$’s in the same level set of $\varphi$. We will show that the level set of $\varphi|_{W^s(\omega)}$ containing the $a_\ell$’s is a 2-sphere crossing $\ell$ at $a_\ell$ only.

As $\varphi$ is a self-indexing energy function for $f$ then $\omega$ is the unique critical point of $\varphi|_{W^s(\omega)}$ and its index is 0. Moreover, in some neighborhood $V(\omega)$ of $\omega$, equipped with Morse coordinates, $\varphi$ reads $\varphi(x) = x_1^2 + x_2^2 + x_3^2$ and hence every regular level set of $\varphi$ near $\omega$ is a smooth 2-sphere which bounds a smooth 3-ball containing $\omega$. According to the Morse theory, for any value $c \in (0, 1)$, $\varphi^{-1}(c) \cap W^s(\omega)$ is also a smooth 2-sphere $S_c^\omega$ which bounds a smooth 3-ball.

\[10\] It is mainly the proof of proposition 2 in Pixton’s article, except that our conclusion is slightly stronger than his; we also take advantage of the fact that our energy function is generic.

\[11\] If $\varphi^{-1}[a, b]$ is compact and does not contain critical points, then $\varphi^{-1}(-\infty, a]$ is diffeomorphic to $\varphi^{-1}(-\infty, b]$ (see, for example, Theorem 3.1 in [3]).
$B_c^\circ \subset W^s(\omega)$ such that $\omega \in f^k(B_c^\circ) \subset \text{int } B_c^\circ$. We choose $c = \varphi^{-1}(a_t)$, a value which does not depend on $\ell$ (see figure 2).

Assume that there is one point $y \neq a_t$ in $\ell \cap S_c^\circ$; certainly $y$ belongs to the interval $(a_t, \omega)$ in $\ell$. We have $y = f^mk(x)$ for some $x \in [a_t, b_t]$ and some positive integer $m$. By the Lyapunov property we have $c = \varphi(y) < \varphi(x) < \varphi(a_t) = c$, which is a contradiction.

Thus, theorem 2 follows directly from lemmas 3.1 and 3.2. The next lemma is useful for the proof of the necessary conditions in theorem 3 (see lemma 3.4).

**Lemma 3.3** For any Morse-Smale diffeomorphism $f : M^3 \to M^3$

$$|\Sigma^-| - |\Omega^-| + 1 = |\Sigma^+| - |\Omega^+| + 1 = g(f).$$

**Proof:** According to [17], a Morse-Smale diffeomorphism induces in all homology groups isomorphisms whose eigenvalues are roots of unity. Thus there is an integer $k$ such that $f^k$ leaves $\text{Per}(f^k)$ fixed, $f^k|_{W^u(p)}$ preserves the orientation of $W^u(p)$ for any point $p \in \text{Per}(f^k)$ and 1 is the only eigenvalue of the isomorphism induced by $f^k$ on homology. Applying the Lefschetz formula to $f^k$ yields

$$\sum_{p \in \text{Per}(f^k)} (-1)^{\dim W^u(p)} = \sum_{i=0}^{3} (-1) t_i,$$

where $t_i$ is the trace of the map induced by $f^k$ on the $i$-th homology group $H_i(M, \mathbb{R})$. By assumption on $k$, $t_i$ coincides with the $i$-th Betti number and the alternating sum of the $t_i$’s is the Euler characteristic, which is 0 since $M$ is an odd-dimensional, closed oriented manifold. So we get $|\Sigma^-| - |\Omega^-| = |\Sigma^+| - |\Omega^+|$. \hfill \Box

**Lemma 3.4** If a Morse-Smale diffeomorphism $f : M^3 \to M^3$ has a self-indexing energy function $\varphi$ then $M^3$ is the union of three domains with mutually disjoint interiors, $M^3 = P^+ \cup N \cup P^-$, satisfying the following conditions.

1) $P^+$ (resp. $P^-$) is a $f$-compressed (resp. $f^{-1}$-compressed) handlebody of genus $g(f)$ and $A(f) \subset P^+$ (resp. $R(f) \subset P^-$);

2) $W^s(\sigma^+) \cap P^+$ (resp. $W^u(\sigma^-) \cap P^-$) consists of exactly one two-dimensional closed disk for each saddle point $\sigma^+ \in \Sigma^+$ (resp. $\sigma^- \in \Sigma^-$);

3) there is a diffeomorphism $q : S_{g(f)} \times [0, 1] \to N$ such that $q(S_{g(f)} \times \{t\})$, $t \in [0, 1]$ bounds an $f$-compressed handlebody.

**Proof:** 1) For $0 < \varepsilon < 1$, we set $P_{\varepsilon}^+ = \varphi^{-1}([0, 1 + \varepsilon])$. According to the Morse theory, it is obtained by gluing $|\Sigma^+|$ 1-handles to an union of $|\Omega^+|$ 12 A 3-dimensional 1-handle is the product of an interval with a 2-disc. The gluing is made along the top and bottom disks (see Section 3 in [18]).
3-balls. Moreover, it is connected since \( M \) itself is connected and any generic path in \( M \), whose end points are in \( P_{\varepsilon}^+ \), may be pushed by the gradient flow of \( \varphi \) into \( P_{\varepsilon}^+ \). Therefore \( P_{\varepsilon}^+ \) is a handlebody of genus \(|\Sigma^+| - |\Omega^+| + 1\), that is \( g(f) \) according to lemma 3.3. As \( \varphi \) is a Lyapunov function, \( P_{\varepsilon}^+ \) is \( f \)-compressed. By definition of a self-indexing energy function and lemma 2.1, \( \varphi(A(f)) = [0, 1] \) and, consequently \( A(f) \subset \text{int} P_{\varepsilon}^+ \). Similarly, using the diffeomorphism \( f^{-1} \), we get that \( P_{\varepsilon}^- = \varphi^{-1}([1 + \varepsilon_0, 2 - \varepsilon_0]) \) is a handlebody of genus \( g(f) \) which \( f^{-1} \)-compressed and contains \( R(f) \) in its interior.

2) As \( \varphi \) is a Morse-Lyapunov function then, for a small enough \( \varepsilon_0 \in (0, \frac{1}{2}) \), the handlebodies \( P^+ = P_{\varepsilon_0}^+ \) and \( P^- = P_{\varepsilon_0}^- \) satisfy the following: \( P^+ \cap W^s(\sigma^+) \) (resp. \( P^- \cap W^s(\sigma^-) \)) consists of exactly one two-dimensional disk \( D_{\sigma^+} \) (resp. \( D_{\sigma^-} \)) for any \( \sigma^+ \in \Sigma^+ \) (resp. \( \sigma^- \in \Sigma^- \)).

3) We take \( N = \varphi^{-1}([1 + \varepsilon_0, 2 - \varepsilon_0]) \). As \( \varphi \) has no critical points on \( N \) and is constant on each boundary component, \( N \) satisfies to condition 3). \( \diamond \)

4 Construction of a self-indexing energy function for a gradient-like diffeomorphism in dimension 3

In this section, the considered manifold is 3-dimensional and \( f : M^3 \to M^3 \) is a gradient-like Morse-Smale diffeomorphism whose set \( L \) of all 1-dimensional separatrices are almost tamely embedded.

4.1 Auxiliary lemmas

**Lemma 4.1** Let \( \omega \) be a sink of period \( k_\omega \) of \( f \) and \( L(\omega) \) be the set of the 1-dimensional separatrices ending at \( \omega \). Then there exists a smooth closed 3-ball \( B \subset W^s(\omega) \), \( \omega \in \text{int} B \), such that:

1) \( B \) is \( f^{k_\omega} \)-compressed;

2) for any \( \ell \subset L(\omega) \) the sphere \( S = \partial B \) crosses \( \ell \) at one point \( a_\ell \) only and transversely.

**Proof:** For simplicity we make \( k_\omega = 1 \). By definition, there exists a closed ball \( B_0 \subset W^s(\omega) \) whose boundary \( S_0 \) meets condition 2). If \( S \) is an embedded sphere in \( W^s(\omega) \) then \( B(S) \) will denote the ball it bounds. If \( S \) meets condition 2), then \( \omega \in \text{int} B(S) \).

Let \( m \) be the first integer such that \( f^k(S_0) \cap S_0 = \emptyset \) for all \( k > m \). For any \( x \in S_0 \) we choose a compact neighborhood \( K_x \) of \( x \) in \( W^s(\omega) \) such that \( f(K_x) \cap K_x = \emptyset \); it exists since \( S_0 \) avoids the fixed point. From the family of the
By a usual transversality theorem ([11, chap. 3]), we may approximate \( S_0 \) in the \( C^\infty \) topology by a sphere having the following property: \( f(S_0 \cap K_1) \) is transversal to \( S_0 \). A next approximation allows one to get such a transversality along \( K_1 \cup K_2 \), and so on. Condition 2) is kept when approximating. Thus, in what follows, we may assume that \( S_0 \) itself is transversal to its successive images \( f(S_0), \ldots, f^m(S_0) \).

In the next step, we are going to modify \( S_0 \) into \( S_1 \) which still fulfills condition 2) and such that \( f^k(S_1) \cap S_1 = \emptyset \) for all \( k \geq m \). Iterating this process will yield the wanted sphere \( S \). Indeed, as \( f(S) \) is disjoint from \( S \) and \( \omega \) is an attractor, we must have \( f(S) \subset \text{int} \; B(S) \), which means that \( B(S) \) is \( f \)-compressed.

Assume first \( m = 1 \) (that is, \( f^k(S_0) \subset \text{int} \; B_0 \) for all \( k \geq 2 \)) and denote \( \Sigma = f(S_0) \). Each intersection curve \( \gamma \) in \( S_0 \cap \Sigma \) bounds a disk \( D \subset \Sigma \). We choose \( \gamma \) to be \textit{innermost} in the sense that the interior of \( D \) contains no intersection curves. Then the curve \( \gamma \) bounds a singular disk \( D' \subset S_0 \) such that \( D \cup D' \) is an embedded 2-sphere homotopic to zero in \( W^s(\omega) \setminus \{ \omega \} \). We notice that \( D \) and \( D' \) have the same number (0 or 1) of intersection points with any one-dimensional separatrix \( \ell \), since \( \Sigma \), as \( S_0 \) does, also satisfies condition 2). We define \( S'_0 \) as the sphere obtained from \( S_0 \) by removing the interior of \( D' \), gluing \( D \) along \( \gamma \), pushing so that \( S'_0 \) avoids \( D \cup D' \), and smoothing \( (S'_0) \) still meets condition 2)). Notice that the intersection curves of \( f^{-1}(S_0) \cap S_0 \) are in bijection by \( f \) with the intersection curves of \( f(S_0) \cap S_0 \). It will be useful to perform the above construction with an innermost disk \( D \subset f^{-1}(S_0) \) instead of \( D \subset f(S_0) \). In both cases, we have to check:

(i) \( f^k(S'_0) \subset B(S'_0) \) for all \( k \geq 2 \) (which is equivalent to \( f^{-k}(S'_0) \cap S'_0 = \emptyset \));

(ii) there are less intersection curves in \( f(S'_0) \cap S'_0 \) than in \( f(S_0) \cap S_0 \).

Point (ii) is not always true; it depends on the position of \( D \) with respect to \( B_0 \). But we shall prove that there always exists an innermost disk \( D \), in \( f(S_0) \) or in \( f^{-1}(S_0) \), such that (ii) is satisfied.

Case 1: \( D \subset f(S_0) \) and \( D \cap \text{int} \; B_0 = \emptyset \). Forgetting the pushing-smoothing, for \( k > 1 \) we have \( f^k(S'_0) \subset f^k(S_0) \cup f^k(\Sigma) = f^k(S_0) \cup f^{k+1}(S_0) \subset \text{int} \; B_0 \subset B(S'_0) \), hence (i) holds. We also have \( f(S'_0) \cap S'_0 \subset (f(S_0) \cup f^2(S_0)) \cap S'_0 \subset f(S_0) \cap S'_0 \), as \( f^2(S_0) \) lies in the interior of \( B_0 \) and \( D \) in its exterior. Hence, (ii) holds after pushing-smoothing.

Case 1’: \( D \subset f^{-1}(S_0) \cap B_0 \). The proof of (i) and (ii) in this case is similar to the previous one in replacing the positive iterates of \( f \) by the negative iterates.

Case 2: \( D \subset f(S_0) \cap B_0 \) and \( D \cap f^2(B_0) = \emptyset \). We have \( f^{2k}(S'_0) \subset B(f^2(S_0)) \), hence disjoint from \( S'_0 \) for all \( k > 0 \). Similarly, \( f^3(S'_0) \) lies in \( f^3(B_0) \subset \text{int} \; (f(B_0) \cap B_0) \), thus it does not intersect \( D \) and (i) holds. Before pushing-smoothing, we have \( f(S'_0) \subset f(S_0) \cup f(D) \). As \( f(D) \) lies
in \( f^2(B_0) \), we have \( f(S'_0) \cap S'_0 \subset f(S_0) \cap S'_0 \). Hence, pushing decreases the number of intersection curves and (ii) holds.

**Case 2**: \( D \subset f^{-1}(S_0) \cap \text{int} f^{-2}(B_0) \) and \( D \cap \text{int} B_0 = \emptyset \). By using the negative iterates of \( f \) one proves that points (i) and (ii) hold.

**Case 3**: \( D \subset f(S_0) \cap B_0 \) and \( D \cap f^2(B_0) \neq \emptyset \). We look at the intersection curves of \( D \) with \( f^2(S_0) \) and choose one of them, \( \alpha \), which is innermost on \( D \): \( \alpha = \partial d \) with \( d \subset D \). There is a unique disk \( d' \) on \( f^2(S_0) \) such that the embedded sphere \( d \cup d' \) does not surround \( \omega \). There are two subcases: (a) \( d \subset f^2(B_0) \) and (b) \( d \subset \text{int} B_0 \setminus \text{int} f^2(B_0) \). When (a), \( f^{-2}(d) \) meets the condition of case 1 and, when (b), it meets the condition of case 2'. In both subcases, points (i) and (ii) hold for this innermost disk. Finally, in any case it is possible to reduce the number of intersection curves of \( S_0 \) with its image, keeping condition 2).

Repeating this process yields \( S_1 \), a sphere meeting condition 2) and such that \( f(S_1) \cap S_1 = \emptyset \), (which implies that \( f(B(S_1)) \) is \( f \)-compressed).

When \( m \geq 1 \), the end of the proof goes as follows. We introduce \( g_r = f^{2^r} \). For \( r \) big enough, we have \( g_r^k(S_0) \cap S_0 = \emptyset \) for all \( k \geq 2 \). According to what we just explained, after changing \( S_0 \) into another sphere \( S_1 \) we get \( g_r(S_1) \cap S_1 = \emptyset \). This amounts to decrease \( r \) by 1: \( g_r^k(S_1) \cap S_1 = \emptyset \) for all \( k \geq 2 \). Recursively, we find a ball satisfying both required conditions. ◆

We now consider the orbit \( O(\omega) \). We just found a ball \( B \subset W^s(\omega) \) such that \( B \) lies in the interior of \( f^{-k\omega}(B) \). We choose a sequence \( B = B_0 \subset B_1 \subset \ldots \subset B_{k\omega-1} \subset f^{-k\omega}(B_\omega) \) with mutually disjoint boundaries. Set \( B_{O(\omega)} = \bigcup_{j=0}^{k\omega-1} f^j(B_j) \).

It is clearly \( f \)-compressed.

**Lemma 4.2** For each \( j = 0, k\omega - 1 \), let \( B_j \subset W^s(f_j(\omega)) \) be a ball centered at \( f_j(\omega) \). The union \( B = \bigcup_{j=0}^{k\omega-1} f^j(B_j) \) is assumed to be \( f \)-compressed. Then there is a self-indexing energy function \( \varphi : B \to \mathbb{R} \) for \( f \) having \( \partial B \) as a level set.

**Proof**: According to lemma 2.2, there is an open neighborhood \( U \) of \( O(\omega) \), \( U \subset B \), and a self-indexing energy function \( \varphi_{O(\omega)} : U \to \mathbb{R} \) for \( f \). A level set of \( \varphi_{O(\omega)} \) whose value is positive and small is the union of \( k\omega \) copies of 2-spheres. For each \( j = 0, k\omega - 1 \), we choose a smooth 3-ball \( Q_j \) in \( U \), centered at \( f^j(\omega) \), with boundary \( G_j \) such that \( G = \bigcup_{j} G_j \) is a level set of \( \varphi_{O(\omega)} \). We denote \( Q = \bigcup_{j} Q_j \), \( S_j = \partial B_j \), \( S = \bigcup_{j} S_j \). In changing \( G \) by a small isotopy we may
assume that $S$ is transversal to $f^{-k}(G)$ for all $k \in \mathbb{N}$. Then $S \cap \left( \bigcup_{k \in \mathbb{N}} f^{-k}(G) \right)$ consists of a finite family $\mathcal{C}$ of closed curves. We have two cases (1) $\mathcal{C} = \emptyset$, (2) $\mathcal{C} \neq \emptyset$.

In case (1), $N$ will denote the least integer such that $f^N(B) \subset \text{int } Q$. We have two subcases (1a) $N = 1$ and (1b) $N > 1$. We first consider (1a). It is known that the domain $B \setminus \text{int } Q$ is diffeomorphic to a union of $k_{\omega}$ copies of $S^2 \times [0, 1]$ (see [10], chap. 8). Hence there is a smooth function $\varphi : B \to \mathbb{R}$ extending $\varphi_{\Omega(\omega)}|Q$ and having no critical point in $B \setminus \text{int } Q$. We claim that $\varphi$ is a self-indexing energy function for $f|_B$. Indeed, for $x \in Q \setminus \Omega(\omega)$, $\varphi(f(x)) > \varphi(x)$ as it is true for $\varphi_{\Omega(\omega)}$. When $x \in B \setminus Q$, we have $\varphi(f(x)) < \varphi(\partial Q) < \varphi(x)$.

Let us consider case (1b) and set $\bar{B} = f^{N-1}(B)$. By the construction $\bar{B}$ is $f$-compressed and satisfies to condition (1a). Hence there is a self-indexing energy function $\tilde{\varphi} : \bar{B} \to \mathbb{R}$ for $f|_{\bar{B}}$. For any $x \in B$, we define $\varphi(x) = \tilde{\varphi}(f^{N-1}(x))$. It is easy to check that $\varphi$ is the required function.

Let us consider case (2). A curve $C \subset \mathcal{C}$ is said innermost on $S$ if $C$ bounds a disk $D_C \subset S$ whose interior contains no intersection curves from $C$. Consider such an innermost curve. We have $C \subset f^{-k_C}(G)$ for some integer $k_C$ and $f^{k_C}(C)$ is an innermost curve on $f^{k_C}(S)$. There is a unique disk $E_C$ in $G$ which is bounded by $f^{k_C}(C)$ such that the sphere $f^{k_C}(D_C) \cup E_C$ is homotopic to zero in $\partial^* \Omega(\omega) \setminus \Omega(\omega)$. We define $G' = (G \setminus E_C) \cup f^{k_C}(D_C)$. It bounds $Q' \subset \partial^* \Omega(\omega)$, a union of 3-balls which contains $\Omega(\omega)$. The fact that $C$ is an innermost curve implies $f(Q') \subset \text{int } Q'$.

There are two occurrences: (2a) $f(Q) \subset Q' \subset Q$ and (2b) $Q \subset Q' \subset f^{-1}(Q)$. In both cases there is a smooth approximation, $\tilde{Q}$ of $Q'$ such that $\tilde{Q} \subset \text{int } Q'$ in case (2a) and $Q' \subset \text{int } \tilde{Q}$ in case (2b); $\tilde{Q}$ is still $f$-compressed. Set $\tilde{G} = \partial \tilde{Q}$. According to item (1a), $f^{-1}(\tilde{G})$ in case (2a) and $\tilde{G}$ in case (2b) is a level set of some self-indexing energy function defined respectively on $f^{-1}(\tilde{Q})$ and on $\tilde{Q}$. By the construction the number of curves in $S \cap \left( \bigcup_{k \in \mathbb{N}} f^{-k}(G) \right)$ is less than in $\mathcal{C}$. We will repeat this process until getting a union of 3-balls $\hat{Q}$ which is $f$-compressed and whose boundary $\hat{G}$ does not intersect $f^k(S)$ for any $k$. Then we are reduced to case (1) and the lemma is proved.

\[\Diamond\]

4.2 A nice neighborhood of the attractor $\mathcal{A}(f)$ (or the repeller $\mathcal{R}(f)$)

Let $f : M^3 \to M^3$ be a gradient-like diffeomorphism whose 1-dimensional separatrices are almost tame. Let us construct a “nice” neighborhood of the standard ball is isotopic to a round ball — a result of J. W. Alexander, 1923. It is also proved that the isotopy extends as an ambient isotopy; hence the claim about the complement of a ball follows.\[\text{\footnote{It is proved in this chapter that any smooth embedding of a ball into the interior of the standard ball is isotopic to a round ball — a result of J. W. Alexander, 1923. It is also proved that the isotopy extends as an ambient isotopy; hence the claim about the complement of a ball follows.}}\]
Figure 3: Construction of a nice neighborhood

attractor $\mathcal{A}(f)$.

According to lemma 2.2, each orbit $O(\sigma), \sigma \in \Sigma^+$, has a neighborhood $U_{O(\sigma)} \subset M^3$ endowed with a Morse-Lyapunov function $\varphi_{O(\sigma)} : U_{O(\sigma)} \to \mathbb{R}$ of $f$. Set $U_{\Sigma^+} = \bigcup_{\sigma \in \Sigma^+} U_{\sigma}$ and denote $\varphi_{\Sigma^+} : U_{\Sigma^+} \to \mathbb{R}$ the function made of the union of the $\varphi_{O(\sigma)}$'s.

Each connected component $U_{\sigma}$ of $U_{\Sigma^+}, \sigma \in \Sigma^+$, is endowed with Morse coordinates $(x_1, x_2, x_3)$ as in the conclusion of lemma 2.2: $\varphi_{\Sigma^+}(x_1, x_2, x_3) = 1 - x_1^2 + x_2^2 + x_3^2$, the $x_1$-axis is contained in the unstable manifold and the $(x_2, x_3)$-plane is contained in the stable manifold.

According to lemma 4.1, there exists an $f$-compressed domain $B^+$, made of $|\Omega^+|$ balls, which is a neighborhood of $\Omega^+$ and such that each separatrix $\ell \in L^+$ intersects $\partial B^+$ in one point $a_\ell$ only. Due to the $\lambda$-lemma (see, for example, [14]), replacing $B^+$ by $f^{-n}(B^+)$ for some $n > 0$ if necessary, we may assume that $\partial B^+$ are transverse to the regular part of the level set $C := \varphi_{\Sigma^+}^{-1}(1)$ and each of the intersections $C \cap \partial B^+$ consists of $2|\Sigma^+|$ circles. Due to lemma 4.2 there is a self-indexing energy function $\varphi_{B^+} : B^+ \to \mathbb{R}$ with a level set $\partial B^+$. For $\varepsilon > 0$ set $B^+_\varepsilon = \varphi_{B^+}^{-1}([0, \varphi_{B^+}(\partial B^+) - \varepsilon])$ and

---

14 The $\lambda$-lemma claims that $f^{-n}(\partial B^+) \cap U_\sigma$ tends to $\{x_1 = 0\} \cap U_\sigma$ in the $C^1$ topology when $n$ goes to $+\infty$.  

16
Figure 4: A pair of nice neighborhoods $(P^+, P^-)$

$E_\varepsilon = (B^+ \setminus \text{int} (B^+_\varepsilon)) \cap \{1 - \varepsilon \leq \varphi_{\Sigma^+} \leq 1 + \varepsilon\}$. We choose $\varepsilon > 0$ such that:

1) $\partial B^+$ and $\partial B^+_\varepsilon$ are transverse to the level sets $\varphi_{\Sigma^+}^{-1}(1 \pm \varepsilon)$, $f(B^+) \subset \text{int} B^+_\varepsilon$ and $(B^+ \setminus \text{int} (B^+_\varepsilon)) \setminus \{\varphi_{\Sigma^+} < 1 - \varepsilon\}$ is a product;

2) $\varphi(f^{-1}(E_\varepsilon)) > 1 + \varepsilon$ (it is possible as $\varphi(f^{-1}(C \setminus \Sigma^+)) > 1$).

We introduce $H^+$, the closure of $\{x \in U_{\Sigma^+} \mid x \notin B^+, \varphi_{\Sigma^+}(x) \leq 1 + \varepsilon\}$ (see figure 4). By construction there is a smoothing $P^+$ of $B^+ \cup H^+$ such that:

- $P^+$ is $f$-compressed;

- $P^+$ is connected (see, for example, [3], lemma 1.3.3));

- $P^+$ is a handlebody of genus $|\Sigma^+| - |\Omega^+| + 1\text{\footnote{By the Mayer-Vietoris exact sequence $\beta_0 - \beta_1 = |\Omega^+| - |\Sigma^+|$, where $\beta_0$, $\beta_1$ are the Betti numbers of $P^+$. Take account of that $\beta_0 = 1$ and $\beta_1$ is the genus of $P^+$.}}$, that is $g(f)$.

We call $P^+$ a nice neighborhood of the attractor $A(f)$ (see figure 4). Making a similar construction for $f^{-1}$ we obtain a nice neighborhood $P^-$ of the repeller $R(f)$, which is also a handlebody of genus $g(f)$ (lemma 3.3).

4.3 Construction of a self-indexing energy function on $P^+$ and $P^-$

Denote $d_\varepsilon$ the part of the level set $\varphi_{\Sigma^+}^{-1}(1 - \varepsilon)$ belonging to $U_{\Sigma^+} \setminus \text{int} B^+_\varepsilon$. By construction $d_\varepsilon$ is the union of $2|\Sigma^+|$ disks. Denote $D'_\varepsilon$ the union of disks in $\partial B^+_\varepsilon$ such that $\partial d_\varepsilon = \partial D'_\varepsilon$. We form $S$, a union of spheres, by removing the
interiors of the $D'_x$ from $\partial B^+_x$ and gluing the $d_x$. Denote $B(S)$ the union of balls bounded by $S$ and containing $\Omega^+$. We check that $B(S)$ is $f$-compressed. Indeed, it is true for $B^+_x$. Moreover, $f(d_x)$ does not intersect $d_x$ nor $\partial B^+_x \setminus D'_x$. The first intersection is empty as $\varphi_{\Sigma^+}$ is a Lyapunov function and $d_x$ lies in a level set of it. The second one is empty as $\varphi_{\Sigma^+}(d_x) = 1 - \varepsilon \leq \varphi_{\Sigma^+}(x)$, for any $x \in U_{\Sigma^+}, x \in \partial B^+_x \setminus D'_x$.

Let $K$ be the domain between $\partial P^+$ and $S$. We define a function $\varphi^+ : K \to \mathbb{R}$ whose value is $1 + \varepsilon$ on $\partial P^+$, $1 - \varepsilon$ on $S$, coinciding with $\varphi_{\Sigma^+}$ on $K \cap H^+$ and without critical points outside $H^+$. This last condition is easy to satisfy as the domain in question is a product cobordism. With all the informations that we have on the image of $f$, it is easy to check that $\varphi^+$ is a Lyapunov function. Indeed, it is obvious for the points of $K$ which are not in $H^+$. Suppose that $x \in K \cap H^+$. Then we have two possibilities: a) $f(x) \in H^+$; b) $f(x) \notin H^+$.

In the first case the conclusion follows from the Lyapunov property of $\varphi_{\Sigma^+}$. In the second case we are going to show that $f(x) \in \{\varphi_{\Sigma^+} < 1 - \varepsilon\}$ and then the conclusion also holds. Suppose on the contrary that $f(x) \notin \{\varphi_{\Sigma^+} < 1 - \varepsilon\}$. Then $f(x)$ belongs to the domain $E_{\varepsilon}$. But it follows from the choice of $E_{\varepsilon}$ that $f^{-1}(E_{\varepsilon})$ does not intersect $H^+$. We get a contradiction.

According to lemma 4.2, there is an extension of $\varphi^+$ to $B(S)$, which is a self-indexing Morse-Lyapunov function. Finally, we get the desired self-indexing energy function on $P^+$.

As the set $\mathcal{R}(f)$ is an attractor of $f^{-1}$ and $P^-$ is a nice neighborhood of $\mathcal{R}(f)$, it is possible to construct (as above) a self-indexing energy function $\hat{\varphi}^- : P^- \to \mathbb{R}$ of $f^{-1}$. It follows from lemma 2.1 that the function $\varphi^- : P^- \to \mathbb{R}$ given by the formula $\varphi^-(x) = -\hat{\varphi}^-(x) + 3$ is a self-indexing energy function of $f$ on $P^-$.

4.4 Proof of theorem 3

The main assumption, which is not a necessary condition, is the following: $M^3 \setminus (A(f) \cup \mathcal{R}(f))$ is diffeomorphic to the product $S_{g(f)} \times \mathbb{R}$.

Let us denote $S^\pm = \partial P^\pm$. It is easy to arrange that $\varphi^-(S^-) > \varphi^+(S^+)$.

First assume $(\ast)$ $S^- \cap (\bigcup_{k>0} f^{-k}(S^+)) = \emptyset$. Let $m$ be the first positive integer such that $f^m(S^-) \subset \text{int } P^+$. If $m = 1$, as $N$ is a product, there exists a smooth function $\varphi : N \to \mathbb{R}$ without critical points which extends $\varphi^+ \cup \varphi^- : P^+ \cup P^- \to \mathbb{R}$. It is a Lyapunov function as $f(N) \subset P^+$ and $f^{-1}(N) \subset P^-$. If $m > 1$, the surfaces $f^{-1}(S^+), f^{-2}(S^+), \ldots, f^{-m+1}(S^+)$ are mutually “parallel”, that is: two by two they bound a product cobordism, diffeomorphic to $S_{g(f)} \times [0,1]$ (see for instance theorem 3.3 in [8]). Therefore they subdivide
N in product cobordisms and there exists a function \( \varphi \) extending \( \varphi^\pm \) on \( P^\pm \), without critical points on \( N \) and having \( f^{-1}(S^+), \ldots, f^{-m+1}(S^+) \) as level sets. One easily checks that such a \( \varphi \) is a self-indexing energy function for \( f \).

We now explain the end of the proof, that is, how to reduce oneself to (*) Without loss of generality we may assume that \( S^- \) is transversal to \( \bigcup_{k>0} f^{-k}(S^+) \), which implies that there is a finite family \( L \) of intersection curves.

We are going to describe (as in lemma 4.2) a process decreasing the number of intersection curves by an isotopy of \( P^+ \) among handlebodies which are \( f \)-compressed; they will be all equipped with a self-indexing energy function which is constant on the boundary.

For simplifying the statement of the next lemma, we use the following definition.

**Definition 4.3** Let \( S \) be a proper bicollared embedded surface in a 3-manifold \( W \) (proper meaning \( \partial S \subset \partial W \) when \( \partial S \neq \emptyset \)). One says that \( S \) is incompressible in \( W \) if any simple curve \( \gamma \) in \( S \) which bounds an embedded disk in \( W \) starting on one side of \( S \) along its boundary, is homotopic to zero in \( S \), and hence bounds an embedded disk in \( S^{16} \).

For instance, our \( S^+ \) and \( S^- \) are incompressible in \( N \).

**Lemma 4.4**
1) Any 2-sphere which is embedded in \( N \), \( P^+ \) or \( P^- \) bounds a ball there.
2) \( S^+ \) (resp. \( S^- \)) is incompressible in \( P^+ \setminus A(f) \) (resp. \( P^- \setminus R(f) \)).
3) \( S^+ \) is incompressible in \( N \cup (P^- \setminus R(f)) \).
4) Both \( S^+ \) and \( S^- \) and their images by \( f^k, k \in \mathbb{Z} \), are incompressible in \( M \setminus (A(f) \cup R(f)) \).

**Proof:**
1) As each of the considered domains embeds into \( \mathbb{R}^3 \), every embedded sphere bounds a 3-ball (generalized Schönflies theorem).

2) Let \( \gamma \) be a simple curve in \( S^+ \) which bounds a disk \( \delta \) in \( P^+ \setminus A(f) \). In changing \( \delta \) by a small isotopy we may assume that \( \delta \) is transverse to \( W^*(\Sigma^+) \); so \( \delta \cap W^*(\Sigma^+) \) consists of a finite family \( \mathcal{I} \) of arcs with end points in \( \gamma \) and a finite family \( \mathcal{L} \) of closed curves. Each arc \( \alpha \in \mathcal{I} \), after some isotopy in \( W^*(\Sigma^+) \) pushing \( \alpha \) into \( S^+ \), indicates a way of decomposing \( \gamma \) as a connected

---

16 It is well known by topologists that this definition is equivalent to the fact that the inclusion \( S \hookrightarrow W \) induces an injection of fundamental groups; but we do not use this deep result.

17 In [4] M. Brown proved the topological statement. A smooth version of this result is available in [5].

19
Similarly, by cut-and-paste, it is possible to remove from \(L\) union of 3-balls, is obtained from \(P\) (that is, \(I\) (that is, \(I = \emptyset\)); thus, \(\gamma\) can be thought of as a curve in \(\partial B^+\) where \(B^+\), a union of 3-balls, is obtained from \(P^+\) by cutting along the disks \(P^+ \cap W^*(\Sigma^+)\).

Similarly, by cut-and-paste, it is possible to remove from \(\mathcal{L}\) the closed curves which bound disks in \(W^*(\Sigma^+) \setminus \Sigma^+\).

First, assume that \(\mathcal{L}\) is empty; in other words, \(\delta \subset B^+\). Thus, there are two disks \(d'\) and \(d''\) in \(\partial B^+\) which is bounded by \(\gamma\). According to item 1), \(\delta\) divides one component of \(B^+\) into two balls \(B'\) and \(B''\), with \(d' \subset B'\) and \(d'' \subset B''\). Since \(\delta \cap A(f)\) is empty and each component of \(B^+\) contains exactly one connected component of \(B^+ \cap A(f)\), one of \(B'\) or \(B''\) is disjoint from \(A(f)\). If it is \(B'\), that means that \(d'\) is a disc in the boundary of \(P^+\). Moreover \(B'\) is a ball in \(P^+ \setminus A(f)\).

In order to finish the proof, we have to consider the case when \(\mathcal{L}\) is not empty, but made of curves which bound disks in \(W^*(\Sigma^+)\) each one having one saddle point in its interior. Let \(e\) be such a curve which is innermost in \(\delta\); it bounds a disk \(d_e \subset W^*(\Sigma^+)\) and a disk \(\delta_e \subset \delta\). Let \(\sigma \in \Sigma^+\) be the saddle point in \(d_e\) and set \(D(\sigma) = P^+ \cap W^*(\sigma)\). After smoothing and a small isotopy, \(d_e \cup \delta_e\) gives rise to an embedded 2-sphere \(S\) which is disjoint from \(W^*(\Sigma^+)\) and, hence, lies in a connected component \(B_0\) of \(B^+\). As \(S\) intersects \(A(f)\) in one point exactly, both separatrices of \(\sigma\) must enter two different connected components of \(B^+\); one being \(B_0\) and the other being denoted \(B_1\). Then \(D(\sigma)\) decomposes \(P^+\) as a connected sum \(P^+ = P_0 \# P_1\), with \(P_j \supset B_j\) for \(j = 0, 1\).

The sphere \(S\) bounds a 3-ball \(B\) in \(B_0\), but, since there is some separatrix of \(\sigma\) which enters \(B\) without getting out, \(B\) must contain one sink \(\omega_0\); moreover, since \(\delta_e\) avoids \(A(f)\), \(\omega_0\) is in the closure of no other separatrix. Hence, \(P_0\) is a ball. If \(\gamma \subset \partial P_0\), there is nothing to do; so, assume \(\gamma \subset \partial P_1\). Since \(\partial P_0\) is a 2-sphere, it is equivalent that \(\gamma\) bounds a disk in \(\partial P^+\) or in \(\partial P_1\). This allows us to ignore \(W^*(\sigma) \cup W^*(\omega_0)\). Repeating this process we are reduced to the case when \(\mathcal{L}\) is empty.

3) As \(N\) is a product, \(S^+\) and \(S^-\) are clearly incompressible in \(N\). One looks at \(\delta\), a disk in \(N \cup P^-\) whose boundary lies in \(S^+\), and at its intersection curves with \(S^-\). Using 2) and the innermost curve techniques, one reduces to the case \(\delta \subset N\) and the conclusion follows.

4) For proving the statement for \(S^+\), we take \(\delta\), an embedded disc in \(M \setminus (A(f) \cup R(f))\) with boundary in \(S^+\) and a collar of \(\partial \delta\) transverse to \(S^+\). Then, in general position, we have finitely many intersection curves in \(\text{int} \delta \cap (S^+ \cup S^-)\). By using 2) and 3) one eliminates successively all intersection curves. Finally, \(\delta\) lies in \(N\) or \(P^+ \setminus A(f)\) and the conclusion follows.
Lemma 4.4 allows us to remove all intersection curves which are homotopic to zero in $S^+$ or, equivalently, in $f^k(S^-)$, $k > 0$ (as in the proof of lemma 4.2). We recall $m$, the largest integer such that $f^m(S^-) \cap S^+ \neq \emptyset$. Let $F^-$ be a connected component of $f^m(S^-) \cap N$. Since $f^m(S^-) \cap S^- = \emptyset$, we have $\partial F^- \subset S^+$. We claim that $F^-$ is incompressible in $N$. Indeed, if $\delta$ is a disk in $N$ with boundary $\gamma \subset F^-$, according to 3) in lemma 4.4, $\gamma$ is homotopic to zero in $f^m(S^-)$. As none of the components of $\partial F^-$ is homotopic to zero, $\gamma$ is homotopic to zero in $F^-$. Therefore, according to F. Waldhausen (corollary 3.2 in [20]), there is some $P^+$ which is isotopic to $P$, $\delta P^+$ is $f$-compressed; moreover $P^+$ carries a self-indexing Lyapunov function. Arguing recursively, we are reduced to case ($\ast$). In this final recursive argument, once lemma 4.4 is proved, it is no longer useful that $P^+$ intersects $W^s(\Sigma^+)$ along disks. This finishes the proof of theorem 4.

4.5 Proof of theorem 4

The necessary condition of theorem 4 is yielded by lemma 3.4. For proving that it is sufficient, we have to construct a self-indexing energy function on $M^3$ under the assumptions of theorem 4 that we recall now. The diffeomorphism $f : M^3 \to M^3$ is a gradient-like diffeomorphism and $M^3$ is the union of three domains with mutually disjoint interiors, $M^3 = P^+ \cup N \cup P^-$, satisfying the following conditions.

1) $P^+$ (resp. $P^-$) is a $f$-compressed (resp. $f^{-1}$-compressed) handlebody of genus $g(f)$ and $A(f) \subset P^+$ (resp. $R(f) \subset P^-$);

2) $W^s(\sigma^+) \cap P^+$ (resp. $W^u(\sigma^-) \cap P^-$) consists of exactly one two-dimensional closed disk for each saddle point $\sigma^+ \in \Sigma^+$ (resp. $\sigma^- \in \Sigma^-$);

3) there is a diffeomorphism $q : S_{g(f)} \times [0,1] \to N$ such that $q(S_{g(f)} \times \{t\})$, $t \in [0,1]$ bounds an $f$-compressed handlebody.

Our assumption makes $P^+$ (resp. $P^-$) very close to a nice neighborhood of $A(f)$ (resp. $R(f)$) in the sense of 4.4. If we remove from $P^+$ a thin neighborhood of the $f$-compressed union of disks $P^+ \cap W^s(\Sigma^+)$, we get a $f$-compressed domain $B^+$, union of $|\Omega^+|$ balls, such that $\partial B^+$ intersects each separatrix $\ell \in L^+$ in one point only. Adding $H^+$ to it (as in 3), we get a new handlebody, we still denote $P^+$, which is a genuine nice neighborhood of $A(f)$. We perform a similar change on $P^-$ and the complement remains a product. We can construct self-indexing energy functions $\varphi^+ : P^+ \to \mathbb{R}$ and $\varphi^- : P^- \to \mathbb{R}$.
as in \[4.3\] which are constant on their respective boundaries. Let us denote \(S^\pm = \partial P^\pm\). It is easy to arrange that \(\varphi^-(S^-) > \varphi^+(S^+).\) Finally we can extend \(\varphi^\pm\) to \(N\) due to condition 3) of the theorem.

5 Example

In this section we construct an example of a Morse-Smale diffeomorphism \(f\) on \(M^3 = S^2 \times S^1\) possessing an energy function and such that \(M^3 \setminus (\mathcal{A}(f) \cup \mathcal{R}(f))\) is not a product. More precisely we prove next proposition.

**Proposition 5.1** There exists a Morse-Smale diffeomorphism \(f : S^2 \times S^1 \to S^2 \times S^1\) with the following properties:

1) the non-wandering set \(\Omega(f)\) consists of four hyperbolic fixed points: \(\omega\) is a sink, \(\sigma^+\) and \(\sigma^-\) are saddles of respective indices 1 and 2, \(\alpha\) is a source, hence \(f\) is gradient-like diffeomorphism for which \(\mathcal{A}(f) = W^u(\sigma^+) \cup \{\omega\}, \mathcal{R}(f) = W^s(\sigma^-) \cup \{\alpha\}\) and \(g(f) = 1\) (with notation introduced after theorem \[3\]):

2) \(M^3 \setminus (\mathcal{A}(f) \cup \mathcal{R}(f))\) is not diffeomorphic to the product \(T^2 \times \mathbb{R}\) (here \(T^2\) is the two-dimensional torus) and \(f\) satisfies the conditions of theorem \[4\] (hence it possesses an energy function).

**Proof:** We first define \(f^+\) on a 3-ball \(B^+\) as the homothety centered at \(\omega\) of ratio \(1/2\). Let \(A^+\) be the closure of \(B^+ \setminus f^+(B^+)\); it is a fundamental domain for \(f^+|_{B^+}\). Let \(d_1^+, d_2^+\) be two disjoint disks in \(\partial B^+\), with respective centers \(a_1^+, a_2^+\), which are used as attaching disks for a 1-handle \(H^+ \cong [-1, +1] \times D^2\), where \(D^2\) is a 2-disk. We have to extend \(f^+\) to \(P^+ = B^+ \cup H^+\) so that the point \(\{0\} \times \{0\}\) of \(H^+\) is a hyperbolic fixed point of index 1, with the core of \(H^+\) as the local unstable manifold and the meridian disk \(\Delta^+ = \{0\} \times D^2\) of \(H^+\) as the stable manifold (take for instance \(f^+|_{\Delta^+}\) as being the \(1/2\)-contraction).

This extension will be essentially determined once we define the embedding \(f^+ :([-1, -\frac{1}{2}] \cup [\frac{1}{2}, 1]) \times D^2 \to A^+\), that is: a pair of disjoint tubes in \(A^+\) joining \(\frac{1}{2}d_1^+, \frac{1}{2}d_2^+\) to \(f^+(d_1^+), f^+(d_2^+)\) respectively. We describe below the cores of these tubes.

For them, we choose a so-called string link \(C^+\) formed with a pair of disjoint arcs \((c_1^+, c_2^+)\) in \(A^+\), each one joining \(a_i^+,\) \(i = 1, 2\) to its image \(f^+\)(\(a_i^+\)). The following properties are required:

i) the pair \((A^+, C^+)\) is not a product \((S^2 \setminus \{x, y\}) \times [0, 1]\);

ii) there exists an involution \(I^+ : (A^+, C^+) \to (A^+, C^+)\) permuting both boundary components of \(A\) such that \(I^+|_{\partial B^+} = f^+\).

An example of such a string link there is shown on figure \[8\] for which involution \(I^+\) is mirror image with respect to middle sphere of \(A^+\). By construction, \(f^+\) is a compression of \(P^+\) with two hyperbolic fixed points, a sink \(\omega\) and a saddle \(\sigma^+\) of index 1. The unstable manifold of \(\sigma^+\) consists of the core of \(H^+\).
and the union $\bigcup_{n\in\mathbb{N}} (f^+)^n(C^+)$. Let $W^+$ be the closure of $P^+ \setminus f^+(P^+)$; it is bounded by two tori.

**Lemma 5.2**

1) The domain $W^+$ is not a product $\mathbb{T}^2 \times [0,1]$.

2) There is an involution $J^+ : W^+ \to W^+$ which permutes both boundary components such that $J^+|_{\partial P^+} = f^+$.

**Proof:**

1) We can see $f^+(P^+)$ as the tubular neighborhood of a closed curve $\kappa^+$ in $P^+$ which intersects $\Delta^+$, the meridian disk of $P^+$, in one point only, namely $\sigma^+$. By cutting $P^+$ along $\Delta^+$, we get a 3-ball $Q^+ \cong B^+$ and a relative knot $\kappa^+ = \kappa^+ \cap Q^+$ which consists of the union of $c_1^+$, $c_2^+$ and an unknotted arc in $f^+(\partial B^+)$ joining $f^+(a_1^+)$ to $f^+(a_2^+)$. If we cut $f^+(P^+)$ along $\Delta^+$, we get a tubular neighborhood of $\kappa^+$. It is easy to prove that condition i) on the chosen string link $C^+$ is equivalent to the following i’):

i’) there is no embedded disk in $Q^+$ whose boundary consists of $\kappa^+$ and one arc in $\partial Q^+$.

Assume that $W^+$ is a product. Then there exists a 2-annulus $R^+$ with one boundary component in $\partial P^+$ and the other consisting of $\kappa^+$. By usual techniques, the intersection $R^+ \cap \Delta^+$ can be reduced to an arc joining both boundary components of $R^+$. Thus, cutting $R^+$ along $\Delta^+$ yields a disk in $Q^+$ whose existence is forbidden by i’).

2) Let $N^+$ be a tubular neighborhood of $C^+$ in $A^+$ which is invariant by $I^+$. The end fibers of $N^+$ consist of the disks $d_1^+$, $d_2^+$ and their images by $f^+$.
Another description of $W^+$ is the following. We remove the interior of $N^+$ (that is, the open tubular neighborhood) and, along $\partial N^+ \cong S^1 \times [0, 1] \times \{-1, 1\}$, we glue $H^+ := S^1 \times [0, 1] \times \{-1, 1\}$. In this description of $W^+$, the restriction of $f^+$ to $\partial P^+ \cap H^+$ is the “identity” of $S^1 \times \{0\} \times [-1, 1] \rightarrow S^1 \times \{1\} \times [-1, 1]$. On the other hand, the involution $I^+$, restricted to $\partial N^+$ is conjugate to $Id|_{[0, 1] \times \tau}$, where $\tau$ is the standard involution of the interval $[0, 1]$. Therefore, $I^+$ extends to $H^+$ as an involution $J^+$ which is the “identity” from $\partial P^+ \cap H^+ \cong S^1 \times \{0\} \times [-1, 1]$ to $f^+(\partial P^+) \cap H^+ \cong S^1 \times \{1\} \times [-1, 1]$. Finally $J^+ = f^+$ on $\partial P^+$. \hfill \diamond

Now, let us consider the quotient $W^+/f^+$ and the natural projection $p^+: W^+ \rightarrow W^+/f^+$. By the above construction $T^+ = p^+(\Delta^+ \cap W^+)$ is a 2-torus. Let $V^+ \cong T^+ \times [-1, 1]$ be a tubular neighborhood of $T^+$ in $W^+/f^+$ and $\hat{h}: W^+/f^+ \rightarrow W^+/f^+$ be a diffeomorphism such that $\hat{h}$ preserves $p^+$, $\hat{h} = id$ outside of $\text{int } V^+$ and $\hat{h}(T^+) \cap T^+ = \emptyset$. Then the lift $h : W^+ \rightarrow W^+$ of $\hat{h}$ preserves $\partial P^+$, commutes with $f^+$ and $h(\Delta^+ \cap W^+ \cap \Delta^+) = \emptyset$.

We now finish the construction of our example. We consider a new copy $P^-$ of $P^+$. We glue them by $h \circ J^+$, viewed as a diffeomorphism $W^- \rightarrow W^+$ where $W^-$ is the copy of $W^+$ in $P^-$. Let $f^- : P^- \rightarrow P^-$ be the copy of $f^+$. Hence, our ambient manifold is $M^3 = P^- \cup_{h \circ J^+} P^+$ and the diffeomorphism $f : M^3 \rightarrow M^3$ is defined by $f|_{P^+} = f^+$ and $f|_{P^-} = (f^-)^{-1}$; one easily checks that both definitions fit together. Our $f$ is a Morse-Smale diffeomorphism as the unstable manifold of $\sigma^-$ avoids the stable manifold of $\sigma^+$.

The repeller $R(f)$ is the attractor of $f^-$, that is the copy of $A(f)$ in $P^-$. By changing $P^-$ into $f^{-1}(P^-)$, then $P^+$ and $f^{-1}(P^-)$ are no longer overlapping; they only have a common boundary and the assumptions of theorem \[\text{[4]}\] are satisfied. This example is the desired one as $M^3 \setminus (A(f) \cup R(f))$ is not the product $\mathbb{T}^2 \times \mathbb{R}$. Indeed, if it would be a product, then $W^+$ itself should be one, contradicting the preceding lemma. \hfill \diamond
