HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Some properties of angular integrals

M. Bergère\(^1\), B. Eynard\(^2\), Institut de Physique Thorique, CEA, IPhT, F-91191 Gif-sur-Yvette, France, CNRS, URA 2306, F-91191 Gif-sur-Yvette, France.

Abstract:

We find new representations for Itzykson-Zuber like angular integrals for arbitrary $\beta$, in particular for the orthogonal group $O(n)$, the unitary group $U(n)$ and the symplectic group $Sp(2n)$. We rewrite the Haar measure integral, as a flat Lebesge measure integral, and we deduce some recursion formula on $n$. The same methods gives also the Shatashvili's type moments. Finally we prove that, in agreement with Brezin and Hikami’s observation, the angular integrals are linear combinations of exponentials whose coefficients are polynomials in the reduced variables $(x_i - x_j)(y_i - y_j)$.

1 Introduction

What we call angular integral \cite{25} is an integral over a compact Lie group $G_{\beta,n}$:

$$G_{1/2,n} = O(n), \quad G_{1,n} = U(n), \quad G_{2,n} = Sp(2n)$$

of the form:

$$I_{\beta,n}(X,Y) = \int_{G_{\beta,n}} dO \ e^{Tr XYO^{-1}}$$

where $X$ and $Y$ are two given matrices, and $dO$ is the Haar invariant measure on the group. We shall also extend $I_{\beta,n}$ to arbitrary $\beta$ (Notice that our $\beta$ is half the one most commonly used in matrix models, for instance we have $\beta = 1$ in the unitary case).

In this paper we are going to consider the case where $X$ and $Y$ are diagonal matrices, however, let us first recall the Harish-Chandra case.
Harish-Chandra case

In the case where $X$ and $Y$ are in the Lie algebra of the group \([22]\) (i.e. real anti-symmetric in the \(O(n)\) case, anti-hermitian in the \(U(n)\) case, and quaternion-anti-self-dual in the \(Sp(2n)\) case), the angular integral can be computed with Weyl-character formula, and is given by the famous Harish-Chandra formula \([10]\) (which is also a special case of the Duistermaat-Heckman localization \([8]\)):

\[
(X,Y) \in \text{Lie algebra} \quad \Rightarrow \quad \int dO \ e^{\text{Tr}XY_0^{-1}} = C \sum_{w \in \text{Weyl}} \frac{e^{\text{Tr}XY_w}}{\Delta_{\beta}(X) \Delta_{\beta}(Y_w)}
\]

where $C$ is a normalization constant, $w$ runs over elements of the Weyl group, and the generalized Vandermonde determinant $\Delta_{\beta}(X)$ is the product of scalar products of positive roots with $X$ (see \([10, 29, 22]\) for details).

Diagonal case

However, for applications to many physics problems \([9, 25]\), it would be more interesting to have $X$ and $Y$ in other representations, and in particular $X$ and $Y$ diagonal matrices.

Since an antihermitian matrix is, up to a multiplication by $i$, a hermitian matrix, and since every hermitian matrix can be diagonalized with a unitary conjugation, for the unitary group, the Harish-Chandra formula applies as well to the case where $X$ and $Y$ are diagonal, this is known as Itzykson-Zuber formula \([18]\):

\[
\begin{aligned}
\quad \left\{
X = \text{diag}(x_1, \ldots, x_n) \\
Y = \text{diag}(y_1, \ldots, y_n)
\right. \\
\Rightarrow \quad \int_{U(n)} dU \ e^{\text{Tr}XYU^{-1}} = C_n \frac{\det e^{y_iy_j}}{\Delta(X) \Delta(Y)}
\end{aligned}
\]

where $\Delta(X) = \Delta_1(X) = \prod_{i>j}(x_i - x_j)$ is the usual Vandermonde determinant.

For the other groups, computing angular integrals has remained an important challenge in mathematical physics for a rather long time. Many progresses and formulae have been found, however, a formula as compact and convenient as Harish-Chandra is still missing. And in particular a formula which would allow to compute multiple matrix integrals, generalizing the method of Mehta \([26]\) is still missing.

Calogero Hamiltonian

It is known that, in the diagonal case, $I_{\beta,n}$ satisfies the Calogero–Moser equation \([4]\), i.e. is an eigenfunction of the Calogero Hamiltonian:

\[
H_{\text{Calogero}} \cdot I_{\beta,n} = \left( \sum_i y_i^2 \right) I_{\beta,n}
\]
Many approaches towards computing angular integrals have used that differential equation. A basis of eigenfunctions of the Calogero Hamiltonian is the Hi-Jack polynomials [4, 2, 7, 24].

In particular remarkable progress in the computation of $I_{\beta,n}$ was achieved recently by Brezin and Hikami [3]. By decomposing $I_{\beta,n}$ on the suitable basis of Zonal polynomials, they were able to find a recursive algorithm to compute the terms in some power series expansion of $I_{\beta,n}$, and they obtained a remarkable structure. In particular they observed that the power series reduces to a polynomial when $\beta \in \mathbb{N}$.

**Morozov and Shatashvili’s formulae**

Another important question for physical applications, is not only to compute the angular integral (the partition function in statistical physics language), but also all its moments, for instance:

$$M_{i,j} = \int_{G_{\beta,n}} dO \ e^{\text{Tr} X O Y O^{-1}} ||O_{i,j}||^2$$

and more generally for any indices $i_1, \ldots, i_{2k}, j_1, \ldots, j_{2k}$:

$$\int_{G_{\beta,n}} dO \ e^{\text{Tr} X O Y O^{-1}} O_{i_1,i_2} O_{i_3,i_4} \ldots O_{i_{2k-1},i_{2k}} O_{j_1,j_2} O_{j_3,j_4} \ldots O_{j_{2k-1},j_{2k}}$$

In the $U(n)$ case $\beta = 1$, Morozov [28] found a beautiful formula for $M_{i,j}$, and Shatashvili [30] found a more general formula for any moments of type 1-8 using the action-angle variables of Gelfand-Tseytlin corresponding to the integrable structure of this integral.

For $\beta = 1/2, 1, 2$, in the Harish-Chandra case where $X$ and $Y$ are in the Lie algebra, a formula for all possible moments was also derived in [29], generalizing Morozov’s [11, 13].

In this article we shall propose new formulae for $M_{i,j}$ in the diagonal case for arbitrary $\beta$, and our method can also be generalized to all moments.

**Outline of the article**

- Section 1 is an introduction, and we present a summary of the main results of this article.

- In section ?? we setup the notations, and we review some known examples.
• In section 4 we show how to transform the angular integral with a Haar measure into a flat Lebesgue measure integral on a hyperplane. From it, we deduce a recursion formula, as well as a duality formula (the angular integral is an eigenfunction of kernel which is the Cauchy determinant to the power $\beta$).

• In section 5 we discuss the moments of the angular integral. We show that moments can be obtained also with Lebesgue measure integrals, and we show that they satisfy linear Dunkl-like equations. This can be used as a way to recover Calogero equation for the angular integral.

• In section 6 we rewrite the angular integral as a symmetric sum of exponentials with polynomial prefactors. Those polynomials are called principal terms, and can be computed recursively. In particular, we prove the conjecture of Brezin and Hikami that the principal terms are polynomials in some reduced variables $(x_i - x_j)(y_i - y_j)$.

• In section 6.2 we prove a formula for $n = 3$ in terms of Bessel polynomials, and we propose a conjecture formula for arbitrary $\beta$ and arbitrary $n$.

• In section 6.4 we focus on the symplectic case $\beta = 2$, for which we can improve the recursion formula.

• Section 7 is the conclusion.

• Appendices contain useful lemmas, and proofs of the most technical theorems.

1.1 Summary of the main results presented in this article

• We rewrite the angular integral with the Haar measure on the Lie group $G_{\beta,n}$, as a flat Lebesgue measure integral on its Lie algebra (notations are explained in section 4):

$$I_{\beta,n}(X;Y) = \int dO \ e^{\text{Tr} XYO^{-1}} = \int dS \ \frac{e^{\text{Tr} S}}{\prod_{k=1}^n \det(S - y_kX)^\beta}$$

(1-9)

as well as its moments:

$$M_{i,j} = \int dO \ ||O_{i,j}||^2 \ e^{\text{Tr} XYO^{-1}}$$

$$= \beta \int dS \ \frac{e^{\text{Tr} S}}{\prod_{k=1}^n \det(S - y_kX)^\beta} \ ((S - y_jX)^{-1})_{i,i}$$

(1-10)
• We show that the $M_{i,j}$'s satisfy a linear functional equation (very similar to Dunkl operators):
\[ \forall i, j, \frac{\partial M_{i,j}}{\partial x_i} + \beta \sum_{k \neq i} \frac{M_{i,j} - M_{k,j}}{x_i - x_k} = M_{i,j} y_j \] (1-11)
which implies the Calogero equation for $I_{\beta,n} = \sum_i M_{i,j} = \sum_j M_{i,j}:
\[ \sum_i \frac{\partial^2 I_{\beta,n}}{\partial x^2_i} + \beta \sum_{j \neq i} \frac{1}{x_i - x_j} \left( \frac{\partial I_{\beta,n}}{\partial x_i} - \frac{\partial I_{\beta,n}}{\partial x_j} \right) = \left( \sum_i y_i^2 \right) I_{\beta,n} \] (1-12)
Moreover, the integral of eq. (1-10), is a solution of the linear functional equation eq. (1-11) for any choice of integration domain (as long as there is no boundary term when one integrates by parts). We thus have a large set of solutions of the linear equation, and also of Calogero equation.

• We deduce a duality formula:
\[ I_{\beta,n}(X; Y) = \det(X)^{1-\beta} \int d\lambda_1 \ldots d\lambda_n \Delta(\Lambda)^{2\beta} \frac{I_{\beta,n}(X, \Lambda)}{\prod_{k=1}^n \prod_{j=1}^n (\lambda_j - y_k)^\beta} \] (1-13)
and a recursion formula:
\[ \hat{I}_{\beta,n}(X; Y) = \frac{I_{\beta,n}(X; Y)}{\prod_{i=1}^n (x_i - x_{n+1})^{2\beta - 1}} \int d\lambda_1, \ldots d\lambda_{n-1} \frac{I_{\beta,n-1}(X_{n-1}, \Lambda) \Delta(\Lambda)^{2\beta} e^{-x_n \sum_i \lambda_i}}{\prod_{k=1}^n \prod_{j=1}^n (\lambda_j - y_k)^\beta} \hat{I}_{\beta,n-1}(X, Y) \] (1-14)
similar to that of [15, 16].

• For $\beta \in \mathbb{N}$, the solution of the recursion can be written in terms of principal terms:
\[ I_{\beta,n}(X, Y) = \sum_\sigma \frac{e^{\sum_{i=1}^n x_i y_{\sigma(i)}}}{\Delta(X)^{2\beta} \Delta(Y_\sigma)^{2\beta}} \hat{I}_{\beta,n}(X, Y_\sigma) \] (1-15)
where $\sum_\sigma$ is the sum over all permutations.

The recursion relation eq. (1-14) can be rewritten as a recursion for the principal terms $\hat{I}_{\beta,n}(X, Y)$:
\[ \hat{I}_{\beta,n}(X_n; Y_n) = \frac{\Delta(Y_n)^{2\beta}}{(\beta - 1)!^{n-1}} \prod_{i=1}^{n-1} x_{i,n} \left( \frac{\partial}{\partial a_i} \right)^{\beta - 1} \hat{I}_{\beta,n-1}(X_{n-1}, a) e^{\sum_{i,n} x_{i,n}(a_i - y_i)} \frac{\prod_{k=1}^n \prod_{i=1, i \neq k}^{n-1} (y_k - a_i)^\beta}{\prod_{i=1}^n (y_k - a_i)^\beta} \bigg|_{a_i = y_i} \] (1-16)
• For general $n$ and $\beta$ integer, we prove the conjecture of Brezin and Hikami [3], that the principal term $\hat{I}_{\beta,n}(X,Y)$ is a symmetric polynomial of degree $\beta$ in the $\tau_{i,j}$ variables,

$$\tau_{i,j} = -\frac{(x_i - x_j)(y_i - y_j)}{2}$$  \hspace{1cm} (1-17)

• In the case $n = 3$ we find this polynomial explicitly for any $\beta$ (for $\beta$ integer the sum is finite):

$$I_{\beta,3} \propto e^{x_1y_1 + x_2y_2 + x_3y_3} \sum_{k=0}^{\infty} \frac{\Gamma(\beta-k)}{\Gamma(\beta+k)} \prod_{i<j} \frac{\gamma_{\beta-1}^{(k)}(\frac{1}{\tau_{ij}})}{\text{sym}}$$  \hspace{1cm} (1-18)

where $\gamma_m$ is the $m^{th}$ Bessel polynomial, i.e. the modified Bessel function of the second kind (see definition of $\gamma_{\beta-1}$ below in eq. (3-4)).

• In the case $\beta = 2$ (i.e. symplectic group $Sp(2n)$), the recursion relation for the principal term can be written:

$$\hat{I}_{2,n} = \prod_{i=1}^{n-1} (x_i - x_n)(y_i - y_n)^2 \prod_{i=1}^{n-1} \left(x_i - x_n - \sum_{k=1,\neq i}^{n} \frac{1}{y_i - y_k} + \frac{\beta}{\partial y_i}\right) \hat{I}_{2,n-1}(X_{n-1},a) \big|_{a_i = y_i}$$  \hspace{1cm} (1-19)

and $B$ is the antisymmetric matrix $B_{i,j} = \frac{\sqrt{2}}{y_i - y_j}$, $B_{i,i} = 0$, and $\partial Y = \text{diag}(\partial y_1, \ldots, \partial y_{n-1})$. In section 6.4 we propose an operator formalism to compute it, and we propose a conjecture formula in terms of decomposition into triangles.

### 2 Definitions and examples

### 3 secdex

#### 3.1 Notations for angular integrals

Let $X$ and $Y$ be two diagonal matrices of size $n$:

$$X = \text{diag}(x_1, \ldots, x_n), \quad Y = \text{diag}(y_1, \ldots, y_n)$$  \hspace{1cm} (3-1)

We define the **angular integral**:

$$I_{\beta,n}(x_1, \ldots, x_n; y_1, \ldots, y_n) = \int_{G_{\beta,n}} \text{d}O \, e^{\text{Tr} X Y O^{-1}}$$  \hspace{1cm} (3-2)
where \( G_{\beta,n} \) denotes one of the Lie groups:

\[
G_{1/2,n} = O(n) \quad , \quad G_{1,n} = U(n) \quad , \quad G_{2,n} = Sp(2n)
\] (3-3)

and \( dO \) is the invariant Haar measure on the corresponding compact Lie group.

We will later extend those notions to arbitrary values of \( \beta \).

### 3.2 Bessel polynomials

For further use, we need to introduce some Bessel functions [1, 23, 31, 32, 5]. Those special functions are going to play a major role throughout this article.

The Bessel polynomials (see [23, 32]) \( \mathcal{Y}_m(x) \) are defined by:

\[
\mathcal{Y}_m(x) = \sum_{k=0}^{\infty} \frac{\Gamma(m+k+1)}{k! \Gamma(m-k+1)} (x/2)^k = \sqrt{\frac{2}{\pi x}} e^{1/x} K_{m+\frac{1}{2}}(1/x)
\] (3-4)

where \( K \) is the modified Bessel function of the second kind [1, 31]. \( \mathcal{Y}_m \) is a polynomial of degree \( m \) when \( m \) is an integer:

\[
\mathcal{Y}_0 = 1, \quad \mathcal{Y}_1 = x + 1, \quad \mathcal{Y}_2 = 3x^2 + 3x + 1, \quad \mathcal{Y}_3 = 15x^3 + 15x^2 + 6x + 1, \quad \text{etc...} \quad (3-5)
\]

They satisfy:

\[
x^2 \mathcal{Y}_m'' + (2x + 2) \mathcal{Y}_m' - m(m + 1) \mathcal{Y}_m = 0 \quad (3-6)
\]

We shall also need:

\[
Q_{\beta,j}(x) = \sum_{k=0}^{\infty} \frac{\Gamma(\beta + j + k)}{k! \Gamma(\beta - j - k)} 2^{-k} x^{\beta-j-k}
\] (3-7)

which is a polynomial of degree \( \beta - j \) if \( \beta \) is an integer.

In particular \( Q_{\beta,0} \) is the Carlitz polynomial [5, 32] and is closely related to \( \mathcal{Y}_{\beta-1} \):

\[
Q_{\beta,0}(x) = x^\beta \mathcal{Y}_{\beta-1}(\frac{1}{x}) = \sqrt{\frac{2}{\pi}} e^x x^{\beta+\frac{1}{2}} K_{\beta-\frac{1}{2}}(x)
\] (3-8)

satisfying:

\[
x^2 Q_{\beta,0}'' - 2x(\beta + x) Q_{\beta,0}' + 2\beta(x + 1) Q_{\beta,0} = 0 \quad (3-9)
\]

The first fews are:

\[
Q_{1,0} = x, \quad Q_{2,0} = x^2 + x, \quad Q_{3,0} = x^3 + 3x^2 + 3x, \quad Q_{4,0} = x^4 + 6x^3 + 15x^2 + 15x, \quad \text{etc...} \quad (3-10)
\]
For higher \( j \), the \( Q_{\beta,j} \)'s are derivatives of Bessel polynomials:

\[
Q_{\beta,j}(1/x) = 2^j x^{j-\beta} \frac{d^j}{dx^j} Y_{\beta-1}(x) = 2^j x^{j-\beta} Y_{\beta-1}^{(j)}(x) \tag{3-11}
\]

They satisfy:

\[-x Q_{\beta,j} = \frac{1}{4} Q_{\beta,j+1} + j Q_{\beta,j} + (j - \beta)(j + \beta - 1)Q_{\beta,j-1} \tag{3-12}\]

\[
Q_{\beta,j+1} = 2(\beta - j - x \frac{d}{dx})Q_{\beta,j} \tag{3-13}
\]

The first fews are:

\[
Q_{2,1} = 2x, \quad Q_{3,1} = 6x^2 + 12x, \quad Q_{4,1} = 12x^3 + 60x^2 + 90x, \quad (3-14)
\]

\[
Q_{3,2} = 24x, \quad Q_{4,2} = 120x^2 + 360x, \quad Q_{4,3} = 720x, \quad \text{etc} \ldots \tag{3-15}
\]

### 3.3 Examples angular integrals with \( n = 1, 2, 3 \)

- **\( n = 1 \):** The \( n = 1 \) case needs no computation, and gives:

\[
I_{\beta,1}(x; y) = e^{xy} \tag{3-16}
\]

- **\( n = 2 \):** The \( n = 2 \) case requires a little bit of easy computation, and it has been known for some time, we have (this formula is rederived in this article):

\[
I_{\beta,2}(X, Y) = \frac{e^{x_1 y_1 + x_2 y_2}}{\tau^\beta} Y_{\beta-1}(1/\tau) + \frac{e^{x_1 y_2 + x_2 y_1}}{(-\tau)^\beta} Y_{\beta-1}(-1/\tau)
\]

\[
= \frac{e^{x_1 y_1 + x_2 y_2}}{\tau^{2\beta}} Q_{\beta,0}(\tau) + \frac{e^{x_1 y_2 + x_2 y_1}}{(-\tau)^{2\beta}} Q_{\beta,0}(-\tau) \tag{3-17}
\]

where

\[
\tau = -\frac{1}{2} (x_1 - x_2)(y_1 - y_2) \tag{3-18}
\]

It can also be written in terms of the modified Bessel function \( I \):

\[
I_{\beta,2}(X; Y) = \frac{e^{\frac{1}{2}((x_1+x_2)(y_1+y_2)}{\tau^{2\beta-1}} I_{\beta-\frac{1}{2}}(\tau) \tag{3-19}
\]

where

\[
I_m(\tau) = (\tau/2)^{2m} \sum_{k=0}^{\infty} \frac{(\tau/2)^{2k}}{k!\Gamma(m + k + 1)} \quad , \quad I_m = I_m'' + \frac{1 - 2m}{\tau} I_m' \tag{3-20}
\]

- **\( n = 3 \):**
we show in this article that (proof in appendix C):

\[
I_{\beta,3} \propto \frac{e^{x_1y_1+x_2y_2+x_3y_3}}{(\Delta(x)\Delta(y))^3} \sum_{k=0}^{\infty} \frac{\Gamma(\beta-k)}{2^{6k}k!\Gamma(\beta+k)} \prod_{i<j} \gamma_{\beta-1}(\frac{1}{\tau_{ij}}) + \text{perm.} \tag{3-21}
\]

where

\[
\tau_{ij} = -\frac{(x_i-x_j)(y_i-y_j)}{2} \tag{3-22}
\]

and +perm. means that we have to symmetrize over all permutations of the \(y_j\)'s.

• \(n > 3\): We show in this article that for arbitrary \(n\) and \(\beta\), the angular integral is of the form conjectured by Brezin and Hikami:

\[
I_{\beta,n} \propto \frac{e^{\sum_i x_iy_i}}{(\Delta(x)\Delta(y))^{2n}} \hat{I}_{\beta,n}(\tau_{ij}) + \text{perm.} \tag{3-23}
\]

where \(\hat{I}_{\beta,n}(\tau_{ij})\) is a polynomial in the \(\tau_{i,j}\)'s, and for which we write a recursion relation.

4 Transformation of the angular integral

In this section, we transform the Haar measure group integral into a flat Lebesgue measure integral.

4.1 Lagrange multipliers

For \(\beta = 1/2, 1, 2\), an element \(O \in G_{\beta,n}\) is an orthonormal basis, i.e. a collection of \(n\) orthonormal vectors \(e_1, \ldots, e_n\), whose coordinates \(O_{i,j} = (e_i)_j\) are of the form:

\[
(e_i)_j = O_{i,j} = \sum_{\alpha=0}^{2\beta-1} (e_i)_j^{\alpha} \epsilon_{\alpha} \tag{4-1}
\]

where the \(\epsilon_{\alpha}\)'s form a basis of a Clifford algebra (indeed this reproduces the three groups \(G_{\beta,n}\) for \(\beta = 1/2, 1, 2\)):

\[
\epsilon_0 = 1, \quad \epsilon_0^\dagger = \epsilon_0, \quad \forall \alpha > 0: \quad \epsilon_\alpha^2 = -1, \quad \epsilon_\alpha^\dagger = -\epsilon_\alpha, \quad \epsilon_\alpha \cdot \epsilon_{\alpha'} = -\epsilon_{\alpha'} \cdot \epsilon_\alpha \tag{4-2}
\]

with structure constants (only for \(\beta = 2\)):

\[
\epsilon_{\alpha} \epsilon_{\alpha'}^\dagger = \sum_{\alpha''} \eta_{\alpha,\alpha',\alpha''} \epsilon_{\alpha''} \tag{4-3}
\]

and where \(\eta_{\alpha,\alpha',\alpha''}\) has the property useful for our purpose, that for every pair \((\alpha, \alpha')\), there is exactly only one \(\alpha''\) such that \(\eta_{\alpha,\alpha',\alpha''} \neq 0\). In particular \(\eta_{\alpha,\alpha,\alpha''} = \delta_{\alpha'',0}\).
The basis must be orthonormal, i.e.

\[ e_i e_j^\dagger = \delta_{i,j} = \sum_{k=1}^{n} (e_i)_k (e_j)_k^\dagger = \sum_{k=1}^{n} \sum_{\alpha,\alpha'=0}^{2\beta-1} (e_i)_k^{\alpha} (e_j)_k^{\alpha'} \epsilon_{\alpha} \epsilon_{\alpha'} \]  

(4-4)

We introduce Lagrange multipliers to enforce those orthonormality relations

\[ \delta(e_i, e_j^\dagger - 1) = \int dS_{i,i} e^{S_{i,i}(1-\sum_{k,\alpha}((e_i)_k^\alpha)^2)} \]  

(4-5)

and if \( i < j \):

\[ \delta(e_i, e_j^\dagger) = \int \ldots \int dS_{i,j}^0 \ldots dS_{i,j}^{2\beta-1} e^{-2\sum_{\alpha,\alpha',\alpha''} \sum_{k} S_{i,j}^\alpha((e_i)_k^\alpha)((e_j)_k^\alpha''))_{\alpha',\alpha''}} \]  

(4-6)

where each integral is over the imaginary axis.

Since the scalar product is invariant under group transformations (i.e. change of orthogonal basis), the following measure is invariant and thus must be proportional to the Haar measure:

\[ dO \propto \prod_{i,j,\alpha} d(e_i)_j^{\alpha} \prod_{i} \delta(e_i, e_i^\dagger - 1) \prod_{i < j} \delta(e_i, e_j^\dagger) \]  

(4-7)

i.e.

\[ dO \propto \prod_{i,j,\alpha} d(e_i)_j^{\alpha} \int dS e^{\sum_{i} S_{i,i} e^{-\sum_{i} \sum_{k} S_{i,j}^\alpha((e_i)_k^\alpha)((e_j)_k^\alpha)^2}}} \]  

(4-8)

where

\[ dS = \prod_{i} dS_{i,i} \prod_{i < j} dS_{i,j} = \prod_{i=1}^{n} dS_{i,i} \prod_{i < j} \prod_{\alpha=0}^{2\beta-1} dS_{i,j}^\alpha \]  

(4-9)

is the \( G_{\beta,n} \) invariant measure on the space \( E_{\beta,n} \):

\[ iS \in \left\{ \begin{array}{l}
E_{1/2,n} = \{ n \times n \text{ real symmetric matrices} \} \\
E_{1,n} = \{ n \times n \text{ hermitian matrices} \} \\
E_{2,n} = \{ n \times n \text{ quaternion self-dual matrices} \}
\end{array} \right\} \]  

(4-10)

where we have completed \( S \) by self duality (\( S = S^\dagger \)):

\[ S_{j,i}^0 = S_{i,j}^0, \quad \text{and} \quad \forall \alpha > 0 \quad S_{j,i}^\alpha = -S_{i,j}^\alpha \]  

(4-11)

Therefore we have (up to a multiplicative constant):

\[ I_{\beta,n}(X;Y) \propto \int dS \int d e_1 \ldots d e_n e^{\sum_{i} S_{i,i} e^{\sum_{i,k} x_i y_k |(e_i)_k|^2}} \]  

10
\[ e^{-\sum_{i} \sum_{k} |S_{i,i} (e_i)_k|^2} \left( e^{-2 \sum_{i<j} \sum_{k} \sum_{\alpha,\alpha',\alpha''} \sum_{i,j} (e_i^\alpha)_k \eta_{\alpha,\alpha',\alpha''} (\delta_{i,j} x_i y_k \delta_{\alpha',0} - S_{i,j}^{\alpha''})} \right) \eta_{\alpha',\alpha'',\alpha} \]

(4 – 12)

The integral over the \((e_i)_k^{\alpha}\)'s is now gaussian and can be performed. The gaussian integrals for each \(k\) are independent.

The quadratic form in the exponential is, for each \(k\):

\[ \sum_{\alpha,\alpha',\alpha''} \sum_{i,j} (e_i^\alpha)_k (e_j^\alpha')_k \eta_{\alpha,\alpha',\alpha''} (\delta_{i,j} x_i y_k \delta_{\alpha',0} - S_{i,j}^{\alpha''}) \]

(4-13)

If we define the vector \(v_k = (v_{1,k}, \ldots, v_{n,k})\) where \(v_i = \sum_{\alpha} (e_i)_k^\alpha e_i^\alpha\), we have to compute the gaussian integral:

\[ \int dv_k e^{-v_k^T (S - y_k X) v_k} \]

(4-14)

For the 3 values of \(\beta = 1/2, 1, 2\), this integral is worth:

\[ \int dv_k e^{-v_k^T (S - y_k X) v_k} = \frac{(2\pi)^\beta}{\det(S - y_k X)^\beta} \]

(4-15)

where \(\det\) is the product of singular values (see [25]).

Thus we get the following theorem:

**Theorem 4.1** The angular integral \(I_{\beta,n}(X; Y)\) is also equal to the following flat Lebesgue measure integral:

\[ I_{\beta,n}(X; Y) \propto \int dS e^{Tr S} \frac{\prod_{k=1}^n \det(S - y_k X)^\beta}{\prod_{k=1}^n \det(S - y_k X)^\beta} = \det(X)^{1-\beta} \int dS e^{Tr SX} \frac{\prod_{k=1}^n \det(S - y_k X)^\beta}{\prod_{k=1}^n \det(S - y_k X)^\beta} \]

(4-16)

In the last formula we have made the change of variable \(S \to X^{1/2} S X^{1/2}\). Also, the integration domain for \(S\), which was \(iE_{\beta,n}\) before exchanging the integrations over \(S\) and \(e\), is now shifted to the right, so that all singular values of \((S - y_k X)\) have positive real part. The integration domain for \(S\) can be deformed such that the integral remains convergent and the integration path goes to the right of all zeroes of the denominator. If \(\beta\) is half-integer or integer, the denominator is not singular near \(\infty\), and the integration contour can be closed. This will be made more precise below.

**Remark 1**: For the moment, this formula holds only for \(\beta = 1/2, 1, 2\). Later we will extend it to other values of \(\beta\).

**Remark 2**: Another remark, is that a similar formula can be obtained by exchanging the roles of \(X\) and \(Y\).
4.2 Duality formula

Notice that the matrix $S$ itself can be diagonalized with a $G_{\beta,n}$ conjugation:

$$S = O \Lambda O^{-1} \quad , \quad \Lambda = \text{diag}(\lambda_1, \ldots, \lambda_n) \quad , \quad O \in G_{\beta,n} \quad (4-17)$$

and the measure $dS$ is up to a constant $2\pi$:

$$dS \propto dO \ d\Lambda \ \Delta(\Lambda)^{2\beta} \quad (4-18)$$

Therefore, the angular integral reappears in the RHS:

$$I_{\beta,n}(X;Y) \propto \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\prod_{k=1}^{n} \det(S - y_k)^\beta} \frac{I_{\beta,n}(X, \Lambda)}{\prod_{k=1}^{n} \prod_{j=1}^{n} (\lambda_j - y_k)^\beta}$$

(4 - 19)

Here, if we assume that $\forall i, x_i \in \mathbb{R}^+$, the integration contours for the $\lambda_i$’s are of the form $r + i\mathbb{R}$ where $r > \max(\text{Re} \ y_k)$. If $\beta$ is integer or half integer, the denominator in the integrand is not singular near $\infty$, and the integration contour can be closed. Thus, if $2\beta$ is an integer, the integration contours for the $\lambda_i$’s can be chosen as circles of radius $> \max(|y_k|)$.

This equation looks better if we rewrite it in term of the Cauchy determinant $D_n(X, Y)$:

$$D_n(X, Y) = \det \left( \frac{1}{x_i - y_j} \right) = \frac{\Delta(X) \Delta(Y)}{\prod_{i,j} (x_i - y_j)} \quad (4-20)$$

and the rescaled function

$$\tilde{I}_{\beta,n}(x_1, \ldots, x_n; y_1, \ldots, y_n) = (\Delta(X) \Delta(Y))^{\beta} I_{\beta,n}(x_1, \ldots, x_n; y_1, \ldots, y_n) \quad (4-21)$$

We then have:

**Theorem 4.2** the rescaled function $\tilde{I}_{\beta,n}$ satisfies the duality formula:

$$\tilde{I}_{\beta,n}(X;Y) \propto \det(X)^{1-\beta} \int d\Lambda \tilde{I}_{\beta,n}(X, \Lambda) \ D_n(\Lambda, Y)^\beta$$

(4-22)

i.e. $\tilde{I}_{\beta,n}(X;Y)$ is an eigenfunction of the kernel $D_n^\beta$.

**Remark 1**: The duality formula above was derived for $\beta = 1/2, 1, 2$, but it makes sense for any $\beta$. 

12
Remark 2: It is easy to check that this relation is satisfied for the Itzykson-Zuber case $\beta = 1$, indeed in that case we have $\tilde{I}_{1,n}(X;Y) = \det(e^{x_i y_j}) = \sum_{\rho} (-1)^{\rho} \prod_i e^{y_i x_{\rho(i)}}$, and:

$$
\int d\Lambda \tilde{I}_{1,n}(X, \Lambda) D_n(\Lambda, Y) \propto \sum_{\sigma, \rho} (-1)^{\sigma} (-1)^{\rho} \prod_{i=1}^n \frac{e^{\lambda_i x_{\rho(i)}}}{\lambda_i - y_{\sigma(i)}} d\lambda_i \\
= \sum_{\sigma, \rho} (-1)^{\sigma} (-1)^{\rho} \prod_{i=1}^n e^{y_{\sigma(i)} x_{\rho(i)}} \\
= n! \det(e^{x_i y_j}) \\
\propto \tilde{I}_{1,n}(X, Y) \quad (4-23)
$$

4.3 Recursion formula

First, let us notice that we can always assume that $x_n = 0$, otherwise we perform a shift $X \rightarrow X - x_n$:

$$
I_{\beta,n}(X, Y) = \int_{G_{\beta,n}} dO \ e^{\text{Tr} XOYO^{-1}} \\
= \int_{G_{\beta,n}} dO \ e^{\text{Tr} (X-x_n)OYO^{-1}} e^{x_n \text{Tr} OYO^{-1}} \\
= e^{x_n \text{Tr} Y} \int_{G_{\beta,n}} dO \ e^{\text{Tr} (X-x_n)OYO^{-1}} \quad (4-24)
$$

Thus we define:

$$
X_{n-1} = \text{diag}(x_1, \ldots, x_{n-1}) \quad , \quad \tilde{X} = X_{n-1} - x_n \text{Id}_{n-1} \quad (4-25)
$$

Then, we notice that the orthonormality of the basis $e_i$:

$$
e_i e_j^\dagger = \delta_{i,j} \quad (4-26)
$$

implies that if we already know $e_1, \ldots, e_{n-1}$, then $e_n$ is completely fixed (up to an irrelevant phase). In other words, it is sufficient to enforce only the orthonormality of $e_1, \ldots, e_{n-1}$ with Lagrange multipliers, i.e. introduce a matrix $S$ of size $n - 1$.

Also, because of our shift $X \rightarrow X - x_n$, we notice that $e_n$ does not appear in the integrand.

Then, we write as in eq (4-8)

$$
dO \propto \prod_{i=1}^{n-1} de_i \prod_{i=1}^{n-1} \delta(e_i, e_i - 1) \prod_{i<j=1}^{n-1} \delta(e_i e_j^\dagger) 
$$
\[ \left[ \prod_{i=1}^{n-1} \prod_{j=1}^{n} \prod_{\alpha=0}^{23-1} d(e_j)^\alpha \int_{iE_{\beta,n-1}} dS \ e^{\sum_i s_i, i} e^{-\sum_i \sum_k s_{i,j}(e_i)k^2} e^{-2\sum_{i<j} \sum_k s_{i,j}(e_i)k} \right] \]

which implies, after performing the gaussian integral over the \( e_1, \ldots, e_{n-1} \):

\[ I_{\beta,n}(X; Y) \propto e^{x_n^\text{tr} Y} \int_{iE_{\beta,n-1}} dS \ e^{\text{Tr} S} \ e^{-\sum_i s_{i,j} e_i^* e_j^\dagger} \]

\[ \propto \prod_{i=1}^{n-1} (x_i - x_n)^{2\beta-1} \int_{iE_{\beta,n-1}} dS \ e^{\text{Tr} s^\dagger X} \prod_{k=1}^{n} \det(S - y_k) \]

\[ (4-28) \]

Again, \( S \) can be diagonalized:

\[ S = O \Lambda O^{-1} \quad , \quad \Lambda = \text{diag}(\lambda_1, \ldots, \lambda_{n-1}) \quad , \quad O \in G_{\beta,n-1} \]

\[ (4-29) \]

i.e. the rank \( n \) angular integral \( I_{\beta,n} \) is expressed in terms of the rank \( n-1 \):

\[ I_{\beta,n}(X; Y) \propto \prod_{i=1}^{n-1} (x_i - x_n)^{2\beta-1} \int d\Lambda \ I_{\beta,n-1}(X_{n-1}, \Lambda) \Delta(\Lambda)^{2\beta} \]

\[ \propto \prod_{k=1}^{n} \prod_{i=1}^{n-1} (\lambda_i - y_k)^\beta \]

\[ (4-30) \]

Which is our main recursion formula:

**Theorem 4.3** The angular integrals \( I_{\beta,n}(X; Y) \) satisfy the recursion:

\[
\begin{array}{c}
I_{\beta,n}(X; Y) \\
\propto e^{x_n \sum_{i=1}^{n} y_i} \int d\lambda_1, \ldots d\lambda_{n-1} \frac{I_{\beta,n-1}(X_{n-1}, \Lambda) \Delta(\Lambda)^{2\beta} e^{-x_n \sum_i \lambda_i}}{\prod_{k=1}^{n} \prod_{i=1}^{n-1} (\lambda_i - y_k)^\beta}
\end{array}
\]

\[ (4-31) \]

Here again, the integration contours for the \( \lambda_i \)'s are such that the integral is convergent, and such that they surround all the \( y_k \)'s. For instance, if \( 2\beta \) is an integer, and if \( \forall i \ x_i \in \mathbb{R}^+ \), the integration contour for the \( \lambda_i \)'s can be chosen as circles of radius \( > \max(|y_k|) \).

**Remark 4.1** Now this recursion formula can be used to define \( I_{\beta,n} \) for arbitrary \( \beta \), so that it coincides with the angular integral for \( \beta = 1/2, 1, 2 \).
We have also the iterated form:

\[
I_{\beta,n}(X;Y) \propto e^{x_n \sum_{i=1}^{n} y_i} \Delta(X)^{2\beta-1} \prod_{i=1}^{n-1} \prod_{j=1}^{i} d\lambda_{i,j} \prod_{i=1}^{n-1} \prod_{1 \leq j < j' \leq i} (\lambda_{i,j'} - \lambda_{i,j})^{2\beta} \prod_{i=1}^{n-1} e^{(x_i-x_{i+1}) \sum_{j} \lambda_{i,j}} \prod_{i=1}^{n-1} \prod_{j=1}^{i} \prod_{j' = 1}^{i'} d\lambda_{i,j'} \prod_{i=1}^{n-1} \prod_{j'=1}^{i'} (\lambda_{i,j'} - \lambda_{i+1,j'})^{\beta} \]

(4.32)

where we have defined \(\lambda_{n,j} = y_j\), and where the integration contours are circles such that:

\[|\lambda_{i,j}| = \rho_i, \quad \rho_1 > \rho_2 > \ldots > \rho_{n-1} > \max |y_j| \quad (4-33)\]

**Remark 4.2** A similar recursion relation was also found Kohler and Guhr [15, 16, 17], but the authors found real integrals instead of contour integrals. The advantage of our formulation, is that we can easily move integration contours and find new relations, as we will see below.

## 5 Moments of angular integrals and Calogero

In this section, we compute moments of the angular integral, and we show that our formula indeed satisfies Calogero equation.

### 5.1 Generalized Morozov’s formula

Define the quadratic moments (see [28] for \(\beta = 1\)):

\[
M_{i,j} = \int_{G_{\beta,n}} dO \ ||O_{i,j}||^2 e^{\text{Tr}XOYO^{-1}}
\]

(5-1)

The same calculation as above yields:

\[
M_{i,j} = \beta \int dS \prod_{k=1}^{n} \det(S - y_k X)^{\beta} ((S - y_j X)^{-1})_{i,i} = \frac{\beta}{x_i} \det(X)^{1-\beta} \int dS \prod_{k=1}^{n} \det(S - y_k)^{\beta} ((S - y_j)^{-1})_{i,i}
\]

(5 - 2)

As a consistency check, and as a warmup exercise, let us show that this formula satisfies:

\[
I_{\beta,n} = \sum_{j} M_{i,j} \quad (5-3)
\]
which comes from \( \forall O \in G_{\beta,n}, \sum_j ||O_{i,j}||^2 = 1. \)

We have:

\[
\sum_j M_{i,j} = \sum_j \frac{\beta}{x_i} \det(X)^{1-\beta} \int dS \prod_{k=1}^n \det(S-y_k)^{\beta} \frac{e^{Tr S X}}{(S-y_j)^{-1}}_{i,i} \\
= \frac{-1}{x_i} \det(X)^{1-\beta} \int dS e^{Tr S X} \frac{\partial}{\partial S_{i,i}} \frac{1}{\prod_{k=1}^n \det(S-y_k)^{\beta}} e^{Tr S X} \\
= \frac{1}{x_i} \det(X)^{1-\beta} \int dS \prod_{k=1}^n \det(S-y_k)^{\beta} \frac{1}{\partial S_{i,i}} e^{Tr S X} \\
= \det(X)^{1-\beta} \int dS \prod_{k=1}^n \det(S-y_k)^{\beta} e^{Tr S X} \\
= I_{\beta,n} \tag{5-4}
\]

Notice that this equality holds independently of the integration domain of \( S \), provided that one can integrate by parts without picking boundary terms.

**Remark:** Of course a similar equation can be found by exchanging the roles of \( X \) and \( Y \), and one gets symmetrically:

\[
\sum_i M_{i,j} = I_{\beta,n} \tag{5-5}
\]

### 5.2 Other moments

Since, after introducing the Lagrange multipliers, the integral becomes gaussian in the \( O_{i,j} \)'s, any polynomial moment can be computed using Wick’s theorem. It is sufficient to compute the propagator:

\[
< O_{i,k} O_{j,l}^{\dagger} > = \beta \delta_{k,l} ( (S-y_k X)^{-1} )_{i,j} \tag{5-6}
\]

Then, the expectation value of any polynomial moment is obtained as the sum over all pairings of the product of propagators.

For instance:

\[
\int dO \; e^{Tr X O Y O^{-1}} O_{i_1,j_1} O_{i_2,j_2} O_{i_3,j_3}^{\dagger} O_{i_4,j_4}^{\dagger} \\
= \int dS \prod_{k=1}^n \det(S-y_k X)^{\beta} \left[ \delta_{j_1,j_3} \delta_{j_2,j_4} ( (S-y_{j_1} X)^{-1} )_{i_1,i_3} ( (S-y_{j_2} X)^{-1} )_{i_2,i_4} \\
+ \delta_{j_1,j_4} \delta_{j_2,j_3} ( (S-y_{j_1} X)^{-1} )_{i_1,i_4} ( (S-y_{j_2} X)^{-1} )_{i_2,i_3} \right] \tag{5-7}
\]

In principle, one could compute with this method the generalization of all Shatashvili’s moments \([30]\).
5.3 Linear equations

In this section we prove that the $M_{i,j}$'s satisfy the following linear functional relations, which are very similar to Dunkl equations $^{[5]}$: 

\[ \forall i, j \quad , \quad \frac{\partial M_{i,j}}{\partial y_j} + \beta \sum_{l \neq j} \frac{M_{i,l} - M_{i,j}}{y_l - y_j} = M_{i,j} x_i \]

(5-8)

We are going to give 2 different proofs of eq. (5-8). The first one below is based on integration by parts. It can be done for the 3 groups $\beta = 1/2, 1, 2$, however it is rather tedious for $\beta = 1/2$ and $\beta = 2$, and we present the proof only for $\beta = 1$. Another proof valid for all 3 values of $\beta$ is presented in section 5.6 below.

Let us check that eq. (5-2) satisfies eq. (5-8) (for $\beta = 1$). We first rewrite:

\[
\frac{1}{y_l - y_j} \left( \frac{1}{S - y_l} - \frac{1}{S - y_j} \right)_{i,i} = ((S - y_l)^{-1}(S - y_j)^{-1})_{i,i} = \sum_m ((S - y_l)^{-1})_{i,m} ((S - y_j)^{-1})_{m,i}
\]

(5-9)

For $\beta = 1$, we may consider all variables $S_{i,m}$ to be independent variables, and we integrate by parts:

\[
\sum_{l \neq j} \frac{M_{i,l} - M_{i,j}}{y_l - y_j} = \sum_{l \neq j} \sum_m \frac{\beta_{x_i}}{x_i} \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\prod_{k=1}^n \det(S - y_k)^\beta} ((S - y_l)^{-1})_{i,m} ((S - y_j)^{-1})_{m,i} \]

\[
= -\sum_m \frac{1}{x_i} \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\det(S - y_l)^{\beta}} \frac{\partial}{\partial S_{i,m}} \frac{1}{\prod_{l \neq j} \det(S - y_l)^{\beta}} ((S - y_l)^{-1})_{i,m} \]

\[
= \sum_m \frac{1}{x_i} \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\prod_{k} \det(S - y_k)^{\beta}} ((S - y)^{-1})_{i,m} x_i \delta_{i,m} - \beta \sum_m \frac{1}{x_i} \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\prod_{k} \det(S - y_k)^{\beta}} ((S - y_l)^{-1})_{i,m} ((S - y_j)^{-1})_{m,i} \]

\[
-\sum_m \frac{1}{x_i} \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\prod_{k} \det(S - y_k)^{\beta}} ((S - y_l)^{-1})_{m,m} ((S - y_j)^{-1})_{i,i} \]

\[
= \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\prod_{k} \det(S - y_k)^{\beta}} ((S - y_l)^{-1})_{i,i} - \frac{1}{x_i} \det(X)^{1-\beta} \int dS \frac{e^{Tr SX}}{\prod_{k} \det(S - y_k)^{\beta}} ((S - y_j)^{-2})_{i,i}
\]
\[-\frac{\beta}{x_i} \det(X)^{1-\beta} \int dS \frac{e^{\text{Tr}sx}}{\prod_k \det(S-y_k)^{\beta}} \text{Tr} (S-y_j)^{-1}((S-y_j)^{-1})_{i,i} \]
\[= \frac{1}{\beta} \left( x_i M_{i,j} - \frac{\partial M_{i,j}}{\partial y_j} \right) \quad (5-10) \]

QED. The same computation can be repeated for \(\beta = 1/2\) and \(\beta = 2\), with additional steps because the variables \(S_{i,m}\) are no longer independent, and also because for \(\beta = 2\), \(\det(S-y_j)\) is defined as the product of singular values. Another proof is given in section 5.6.

**Remark:** Of course a similar equation can be found by exchanging the roles of \(X\) and \(Y\), and one gets the symmetric linear equation:
\[
\forall i, j \quad , \quad \frac{\partial M_{i,j}}{\partial x_i} + \beta \sum_{l \neq i} \frac{M_{i,j} - M_{k,j}}{x_l - x_i} = M_{i,j} y_j \quad (5-11) \]

**Remark:** again, this proves that eq. (5-2) is solution of the differential equation eq. (5-8), for any choice of integration domain provided that we can integrate by parts. In fact, by taking linear combinations of all possible integration contours, we get the general solution of the linear equation eq. (5-8). However, a general solution of eq. (5-8) is not necessarily symmetric in \(X\) and \(Y\), and does not necessarily obey eq. (5-11).

### 5.4 Calogero equation

Here, we prove that \(I_{\beta,n}\) satisfies the Calogero equation.

Start from the linear equation:
\[
\frac{\partial M_{i,j}}{\partial x_i} + \beta \sum_{k \neq i} \frac{M_{i,j} - M_{k,j}}{x_i - x_k} = M_{i,j} y_j \quad (5-12) \]

then sum over \(j\), using eq. (5-3):
\[
\frac{\partial}{\partial x_i} = \sum_j M_{i,j} y_j \quad (5-13) \]

Then apply \(\frac{\partial}{\partial x_i}\):
\[
\frac{\partial^2 I}{\partial x_i^2} = \sum_j y_j \frac{\partial M_{i,j}}{\partial x_i}
= \sum_j y_j \left( M_{i,j} y_j - \beta \sum_{k \neq i} \frac{M_{i,j} - M_{k,j}}{x_i - x_k} \right)
= \sum_j y_j^2 M_{i,j} - \beta \sum_j y_j \sum_{k \neq i} \frac{M_{i,j} - M_{k,j}}{x_i - x_k} \]

18
\[
\sum_j y_j^2 M_{i,j} - \beta \sum_{k \neq i} \frac{\partial I}{\partial x_i} \frac{\partial I}{\partial x_k} - \beta \sum_k \partial I \partial x_k
\]

(5 - 14)

If we take the sum over \(i\), using eq. (5-5), we get:

\[
\sum_i \frac{\partial^2 I}{\partial x_i^2} + \beta \sum_i \sum_{k \neq i} \frac{\partial I}{\partial x_i} \frac{\partial I}{\partial x_k} = \sum_j y_j^2 I
\]

(5-15)

i.e. we recover the Calogero equation:

\[
H_{\text{Calogero}}. I_{\beta,n} = (\sum_j y_j^2) I_{\beta,n}
\]

(5-16)

### 5.5 Matrix form of the linear equations

The linear equations, are \(n^2\) linear equations of order 1, for \(n^2\) unknown functions \(M_{i,j}\).

They can be summarized into a matricial equation:

\[
MY = KM
\]

(5-17)

where \(K\) is a matricial operator

\[
K_{ii} = \frac{\partial}{\partial x_i} + \beta \sum_{k \neq i} \frac{1}{(x_i - x_k)} \quad , \quad K_{ik} = -\frac{\beta}{(x_i - x_k)} \quad i \neq k
\]

(5-18)

and more generally this implies:

\[
MY^p = K^p M
\]

(5-19)

and therefore, for any polynomial \(P\):

\[
M.P(Y) = P(K).M
\]

(5-20)

In particular if we choose the characteristic polynomial of \(Y\):

\[
0 = \prod_{i=1}^n (y_i - K) . M
\]

(5-21)

Let us introduce the vector

\[
e = (1, 1, \ldots, 1)^t
\]

(5-22)
It is such that \( M \) is a stochastic matrix, i.e.:

\[
M \cdot e = I_{\beta,n} e, \quad e^t \cdot M = I_{\beta,n} e^t
\]

We thus have, for any polynomial \( P \):

\[
e^t P(K) \cdot I_{\beta,n} = I_{\beta,n} \quad \text{Tr} \ P(Y)
\]

Notice that the Calogero equation is the case \( P(K) = K^2 \).

If \( P \) is the characteristic polynomial of \( Y \) we get another differential equation for \( I_{\beta,n} \):

\[
\forall i, \quad \sum_j \left( \prod_{l=1}^{n} (y_l - K) \right)_{i,j} \cdot I_{\beta,n} = 0
\]

And if \( P(K) = \prod_{l \neq j} (y_l - K) \), we get:

\[
M_{i,j} = \sum_m \left( \prod_{l \neq j} \frac{y_l - K}{y_l - y_j} \right)_{i,m} \cdot I_{\beta,n}
\]

This last relation allows to reconstruct \( M_{i,j} \) if we know \( I_{\beta,n} \).

Finally, before leaving this section, we just mention that those operators \( K_{i,j} \) are also related to the Laplacian over the set of matrices \( E_{\beta,n} \), as was noted recently by Zuber [34].

### 5.6 Linear equation from loop equations

There is another way of deriving those Dunkl-like linear equations for the angular integrals, using loop equations of an associated 2-matrix model.

Consider the following 2-matrix integral, where \( M_1 \) and \( M_2 \) are both in the \( E_{\beta,n} \) ensemble:

\[
Z = \int dM_1 dM_2 \ e^{-\text{Tr} (V_1(M_1)+V_2(M_2)-M_1 M_2)}
\]

After diagonalization of \( M_1 = O_1 X O_1^{-1} \) and \( M_2 = O_2 Y O_2^{-1} \), we have:

\[
Z = \int dX dY dO_1 dO_2 \ \Delta(X)^{2\beta} \Delta(Y)^{2\beta} \ e^{-\text{Tr} (V_1(X)+V_2(Y))} \ e^{\text{Tr} X O_1^{-1} O_2 Y O_2^{-1} O_1}
\]

We redefine \( O_2 = O_1 O \), and the integral over \( O_1 \) gives 1, and the integral over \( O \) gives the angular integral:

\[
Z = \int dX dY \ \Delta(X)^{2\beta} \Delta(Y)^{2\beta} \ e^{-\text{Tr} (V_1(X)+V_2(Y))} \ I_{\beta,n}(X,Y)
\]
We can do a similar change of variable for moments:

\[
\begin{align*}
< \text{Tr} \frac{1}{x - M_1} \frac{1}{y - M_2} > &= \frac{1}{Z} \int dM_1 dM_2 e^{-\text{Tr}(V_1(M_1)+V_2(M_2)-M_1M_2)} \text{Tr} \left( \frac{1}{x - M_1} \frac{1}{y - M_2} \right) \\
&= \frac{1}{Z} \int dX dY dO_1 dO_2 \Delta(X)^{2\beta} \Delta(Y)^{2\beta} e^{-\text{Tr}(V_1(X)+V_2(Y))} \\
&\quad \times e^{\text{Tr} X O_1^{-1} O_2 Y O_2^{-1} O_1} \text{Tr} \left( \frac{1}{x - X} O_1^{-1} O_2 \frac{1}{y - Y} O_2^{-1} O_1 \right) \\
&= \frac{1}{Z} \int dX dY \Delta(X)^{2\beta} \Delta(Y)^{2\beta} e^{-\text{Tr}(V_1(X)+V_2(Y))} \\
&\quad \times \sum_{i,j} M_{i,j}(X, Y) \frac{1}{x - x_i} \frac{1}{y - y_j}
\end{align*}
\]

(5 - 30)

where \(M_{i,j}(X, Y)\) is the Morozov moment defined in eq. 5-1.

Loop equations amount to say that an integral is invariant under a change of variables. Thus, we change \(M_1 \rightarrow M_1 + \epsilon \frac{1}{x - M_1} \frac{1}{y - M_2} + O(\epsilon^2)\) in \(Z\), and to order 1 in \(\epsilon\) we get (the loop equations for \(\beta = 1/2, 1, 2\) ensembles can be found in several references [1], the Jacobian is easily computed in eigenvalue representation, see appendix [I] eq. (2-8)):

\[
0 = \left\langle \text{Tr} \frac{1}{x - M_1} \frac{M_2}{y - M_2} \right\rangle - \left\langle \text{Tr} \frac{V'(M_1)}{x - M_1} \frac{1}{y - M_2} \right\rangle \\
+ \beta \left\langle \text{Tr} \frac{1}{x - M_1} \frac{1}{y - M_2} \right\rangle \\
+ (\beta - 1) \frac{\partial}{\partial x} \left\langle \text{Tr} \frac{1}{x - M_1} \frac{1}{y - M_2} \right\rangle
\]

(5 - 31)

i.e., going to eigenvalues \(M_1 = O_1 X O_1^{-1}\) and \(M_2 = O_2 Y O_2^{-1}\):

\[
0 = \sum_{i,j} \left\langle \frac{(y_j - V'(x_i)) M_{i,j}(X, Y)}{(x - x_i)(y - y_j)} \right\rangle \\
+ \beta \sum_{i \neq l} \sum_{j} \left\langle \frac{M_{i,j}(X, Y)}{(x - x_l)(x - x_i)(y - y_j)} \right\rangle \\
+ \sum_{i,j} \left\langle \frac{M_{i,j}(X, Y)}{(x - x_i)^2(y - y_j)} \right\rangle
\]

(5 - 32)

The last term can be integrated by parts:

\[
\sum_{i,j} \left\langle \frac{M_{i,j}(X, Y)}{(x - x_i)^2(y - y_j)} \right\rangle
\]

21
\[
\sum_{i,j} \int dX \, dY \, \Delta(X)^{2\beta} \Delta(Y)^{2\beta} \, e^{-\text{Tr}(V_1(X)+V_2(Y))}
\]
\[
M_{i,j}(X,Y) \frac{\partial}{\partial x_i} \frac{1}{(x-x_i)\,(y-y_j)}
\]
\[
= -\sum_{i,j} \int dX \, dY \frac{1}{(x-x_i)\,(y-y_j)} \, \frac{\partial}{\partial x_i} M_{i,j}(X,Y) \, \Delta(X)^{2\beta} \Delta(Y)^{2\beta} \, e^{-\text{Tr}(V_1(X)+V_2(Y))}
\]
\[
= \sum_{i,j} \int dX \, dY \frac{M_{i,j}(X,Y)}{(x-x_i)\,(y-y_j)} \, \Delta(X)^{2\beta} \Delta(Y)^{2\beta} \, e^{-\text{Tr}(V_1(X)+V_2(Y))} \left( V'_1(x_i) - \sum_{l \neq i} \frac{2\beta}{x_i-x_l} \right)
\]
\[
= \sum_{i,j} \left\langle \frac{1}{(x-x_i)\,(y-y_j)} \, \frac{\partial M_{i,j}(X,Y)}{\partial x_i} \right\rangle
\]

Therefore we have:

\[
\sum_{i,j} \left\langle \frac{1}{(x-x_i)\,(y-y_j)} \, \frac{\partial M_{i,j}(X,Y)}{\partial x_i} \right\rangle
\]
\[
= \sum_{i,j} \left\langle \frac{y_j M_{i,j}(X,Y)}{(x-x_i)\,(y-y_j)} \right\rangle - 2\beta \sum_{l \neq i} \sum_{j} \left\langle \frac{M_{i,j}(X,Y)}{(x-x_i)(x-x_l)(y-y_j)} \right\rangle
\]
\[
+ \beta \sum_{i \neq l} \sum_{j} \left\langle \frac{M_{i,j}(X,Y)}{(x-x_l)(x-x_i)(y-y_j)} \right\rangle
\]
\[
= \sum_{i,j} \left\langle \frac{y_j M_{i,j}(X,Y)}{(x-x_i)(y-y_j)} \right\rangle - 2\beta \sum_{l \neq i} \sum_{j} \left\langle \frac{M_{i,j}(X,Y)}{(x-x_i)(x-x_l)(y-y_j)} \right\rangle
\]
\[
+ \beta \sum_{i \neq l} \sum_{j} \left\langle \frac{M_{i,j}(X,Y)}{(x-x_l)(x-x_i)(y-y_j)} \right\rangle
\]
\[
+ \beta \sum_{i \neq l} \sum_{j} \left\langle \frac{M_{i,j}(X,Y)}{(x-x_i)(x_l-x_i)(y-y_j)} \right\rangle
\]
\[
= \sum_{i,j} \left\langle \frac{y_j M_{i,j}(X,Y)}{(x-x_i)(y-y_j)} \right\rangle
\]
\[
- \beta \sum_{l \neq i} \sum_{j} \left\langle \frac{1}{(x-x_i)(y-y_j)} \, \frac{M_{i,j}(X,Y) - M_{i,j}(X,Y)}{(x-x_l)} \right\rangle
\]

(5–33)
Since this equation must hold for any $V_1$ and $V_2$, $x$, $y$, i.e. for any measure on $X$ and $Y$, it must hold term by term i.e. we recover the linear equation:

$$\frac{\partial M_{i,j}(X,Y)}{\partial x_i} = y_j M_{i,j}(X,Y) - \beta \sum_{l \neq i} \frac{M_{i,j}(X,Y) - M_{l,j}(X,Y)}{(x_i - x_l)}$$  \hspace{1cm} (5-35)

Of course, the loop equation coming from the change of variable $M_2 \rightarrow M_2 + \epsilon \frac{1}{x-M_1} \frac{1}{y-M_2} + O(\epsilon^2)$ gives the symmetric linear equation:

$$\frac{\partial M_{i,j}(X,Y)}{\partial y_j} = x_i M_{i,j}(X,Y) - \beta \sum_{l \neq j} \frac{M_{i,j}(X,Y) - M_{i,l}(X,Y)}{(y_j - y_l)}$$  \hspace{1cm} (5-36)

QED.

6 Principal terms and the $\tau_{i,j}$ variables

As we mentioned in the introduction, it was noticed in particular by Brezin and Hikami [3], that the angular integral can be written as combinations of exponential terms, and polynomials (for $\beta$ integer, series otherwise), of some reduced variables $\tau_{i,j} = -\frac{1}{2} (x_i - x_j)(y_i - y_j)$. Here, we show how our recursion gives such a form.

We thus define:

**Definition 6.1** We define the principal term $\hat{I}_{\beta,n}(X; Y)$ from the recursion:

$$\begin{align*}
\hat{I}_{\beta,1} &= 1 \\
\hat{I}_{\beta,n}(X_n; Y_n) &= \Delta(Y_n)^{2\beta} \prod_{i=1}^{n-1} (x_i - x_n) \text{Res}_{\lambda_i \rightarrow y_n} \frac{d\lambda_1}{(\lambda_1 - y_1)^{\beta}} \cdots \frac{d\lambda_{n-1}}{(\lambda_{n-1} - y_{n-1})^\beta} \\
&\quad \times \frac{\hat{I}_{\beta,n-1}(X_{n-1}, \Lambda) e^{\sum_i (x_i - x_n)(\lambda_i - y_n)}}{\prod_{k=1}^{n} \prod_{i=1, i \neq k}^{n-1} (y_k - \lambda_i)^\beta} \\
&= (6-1)
\end{align*}$$

It is such that (the sum over permutations comes from the sum of residues at all poles in recursion eq. (4-31) of theorem. 4.3):

$$I_{\beta,n}(X,Y) = \sum_\sigma \frac{e^{\sum_{i=1}^{n} x_i y_{\sigma(i)}}}{\Delta(X)^{2\beta} \Delta(Y_\sigma)^{2\beta}} \hat{I}_{\beta,n}(X,Y_\sigma)$$  \hspace{1cm} (6-2)

In [3], Brezin and Hikami observed and conjectured that when $\beta$ is an integer, $\hat{I}_{\beta,n}(X,Y)$ is a polynomial in the variables $\tau_{i,j} = -\frac{1}{2} (x_i - x_j)(y_i - y_j)$.
For instance, if $\beta = 1$, we have for arbitrary $n$:

$$\hat{I}_{1,n} = \prod_{i<j} \tau_{i,j}$$  \hspace{1cm} (6-3)

And, if $n = 2$, we have for arbitrary $\beta$:

$$\hat{I}_{\beta,2} = (x_1 - x_2) (y_1 - y_2)^{2\beta} \frac{d\lambda}{\lambda^\beta} \text{Res}_{\lambda=0} \frac{e^{(x_1-x_2)\lambda}}{(y_2 - y_1 - \lambda)^\beta}$$

$$= (x_1 - x_2) (y_1 - y_2)^{2\beta} \beta^{-1} \left( \frac{e^{(x_1-x_2)\lambda}}{(y_2 - y_1 - \lambda)^\beta} \right)_{\lambda=0}$$

$$= (x_1 - x_2) (y_1 - y_2)^{2\beta} \sum_{k=0}^{\beta-1} \frac{(\beta - 1)!}{k!(\beta - 1 - k)!} (x_1 - x_2)^{\beta-1-k} (y_2 - y_1)^{-k} \frac{(\beta - 1 + k)!}{(\beta - 1)!}$$

$$= \sum_{k=0}^{\beta-1} \frac{(\beta - 1 + k)!}{k!(\beta - 1 - k)!} ((x_1 - x_2)(y_2 - y_1))^{\beta-k}$$

$$= 2^\beta Q_{\beta,0}(\tau_{1,2})$$  \hspace{1cm} (6-4)

i.e. we recover the well known result that $\hat{I}_{\beta,2}$ is the Bessel polynomial of degree $\beta$.

We are going to prove the conjecture of Brezin Hikami for all $n$ and for all $\beta \in \mathbb{N}$, but first, let us prove some preliminary properties:

**Lemma 6.1** $\hat{I}_{\beta,n}$ is a polynomial in all variables $x_i$ and $y_j$, and it is symmetric under the exchange $X \leftrightarrow Y$, and under the permutation of pairs $(x_i, y_i) \leftrightarrow (x_j, y_j)$, and under translations $X \rightarrow X + \text{cte.Id}$ or $Y \rightarrow Y + \text{cte.Id}$.

**proof:**

If $\beta$ is an integer, the recursion relation eq. (6-1) leads to (we write $x_{i,j} = x_i - x_j$, $y_{i,j} = y_i - y_j$):

$$\hat{I}_{\beta,n+1} = \prod_{i=1}^{n} x_{n+1,i} y_{n+1,i} \left( \frac{\partial}{\partial \lambda_i} \right)^{\beta-1} e^{x_{i,n+1} \lambda_i} \prod_{1 \leq j \leq n+1, j \neq i} \frac{y_{j,i}^\beta}{(y_{j,i} - \lambda_i)^\beta} \hat{I}_{\beta,n}(X_n, Y_n + \Lambda) \bigg|_{\Lambda=0}$$

$$= \prod_{i=1}^{n} x_{i,n+1} y_{n+1,i} \left( \frac{\partial}{\partial \lambda_i} \right)^{\beta-1} e^{x_{i,n+1} \lambda_i} \prod_{1 \leq j \leq n+1, j \neq i} \frac{y_{j,i}^\beta}{(y_{j,i} - \lambda_i)^\beta} \hat{I}_{\beta,n}(X_n, Y_n + \Lambda) \bigg|_{\Lambda=0}$$

(6-5)

which shows by recursion, that $\hat{I}_{\beta,n+1}$ is a rational function of all $x_i$’s and $y_j$’s.

We know, from its very definition, that the angular integral

$$I_{\beta,n}(X, Y) = \sum_{\sigma} \frac{e^{\sum_{i=1}^{n} x_{i,\sigma(i)} y_{i,\sigma(i)}}}{\Delta(X)^{2\beta} \Delta(Y)^{2\beta}} \hat{I}_{\beta,n}(X, Y_\sigma)$$  \hspace{1cm} (6-6)
is symmetric in all \(x_i\)'s and \(y_j\)'s, and in the exchange \(X \leftrightarrow Y\). Since the exponentials are linearly independent on the ring of rational functions, each term must be symmetric in permutations of pairs \((x_i, y_j)\)'s, i.e. \( \hat{\mathcal{I}}_{\beta,n}(x_1, \ldots, x_n; y_1, \ldots, y_n) \) is a symmetric function of the pairs \((x_i, y_j)\)'s, and also symmetric under \(X \leftrightarrow Y\).

Moreover, \( \hat{\mathcal{I}}_{\beta,n+1} \) is clearly a polynomial in the variables \(x_{n+1}\) and \(y_{n+1}\), and because of the symmetry, it must also be a polynomial in all variables. Translation invariance is also clear from the recursion formula.

\[ \square \]

**Theorem 6.1 (Conjecture of Brezin-Hikami):**

\( \hat{\mathcal{I}}_{\beta,n} \) is a symmetric polynomial of degree \(\beta\) in the \(\tau_{i,j}\)'s.

**proof:**

Using lemma 6.1 it is easy to see that \( \hat{\mathcal{I}}_{\beta,n} \) fulfills the hypothesis of lemma A.3 in the appendix A and this proves the theorem. \( \square \)

I.e. we have proved the conjecture of Brezin and Hikami [3]. In fact, we notice that the property of being a polynomial in the \(\tau\)'s, is not specific to angular integrals, but comes only from the global symmetries.

### 6.1 Recursion without residues for \(\beta\) integer

For \(\beta \in \mathbb{N}\), the residues in recursion eq. (6-1) can be performed, and they compute derivatives of the integrand. Thus eq. (6-1) can be rewritten:

\[
\begin{align*}
\hat{\mathcal{I}}_{\beta,n}(X_n; Y_n) & = (Y_n)^{2\beta} \prod_{i=1}^{n-1} (x_i - x_n) \prod_{k=1}^{n} \Delta(Y_{n-1}; \Lambda) e^{\sum_{i=1}^{n} (x_i - x_n)(\lambda_i - y_i)} \\
& = \Delta(Y_n)^{2\beta} \prod_{i=1}^{n-1} (x_i - x_n) \prod_{k=1}^{n} \frac{\partial}{\partial a_i} \left( \frac{\partial}{\partial a_i} \right)^{\beta-1} \prod_{i=1}^{n} \frac{d\lambda_i}{(\lambda_i - a_1)^\beta} \prod_{n-1}^{\beta-1} d\lambda_{n-1} \\
& = \Delta(Y_n)^{2\beta} \prod_{i=1}^{n-1} (x_i - x_n) \prod_{k=1}^{n} \frac{\partial}{\partial a_i} \left( \frac{\partial}{\partial a_i} \right)^{\beta-1} \prod_{i=1}^{n} \frac{d\lambda_i}{(\lambda_i - a_1)^\beta} \prod_{n-1}^{\beta-1} d\lambda_{n-1} \\
& = \Delta(Y_n)^{2\beta} \prod_{i=1}^{n-1} (x_i - x_n) \prod_{k=1}^{n} \frac{\partial}{\partial a_i} \left( \frac{\partial}{\partial a_i} \right)^{\beta-1} \prod_{i=1}^{n} \frac{d\lambda_i}{(\lambda_i - a_1)^\beta} \prod_{n-1}^{\beta-1} d\lambda_{n-1} \\
(6-7)
\end{align*}
\]

i.e. we can perform the residues:

\[
\hat{\mathcal{I}}_{\beta,n}(X_n; Y_n) = \Delta(Y_n)^{2\beta} \prod_{i=1}^{n-1} x_{i,n} \left( \frac{\partial}{\partial a_i} \right)^{\beta-1} \prod_{k=1}^{n} \frac{\partial}{\partial a_i} \left( \frac{\partial}{\partial a_i} \right)^{\beta-1} \prod_{i=1}^{n} \frac{d\lambda_i}{(\lambda_i - a_1)^\beta} \prod_{n-1}^{\beta-1} d\lambda_{n-1} \\
(6-8)
\]
More explicitly

\[ \tilde{I}_{\beta,n}(X_n; Y_n) = \prod_{i=1}^{n-1} \sum_{\gamma_i, \beta_i,k=0}^{\beta-1} \frac{(x_{i,n}y_{n,i})^{\beta_i,n}}{\Gamma(\beta - \gamma_i - \sum_k \beta_{i,k}) \beta_{i,n}!} \prod_{k=1,k\neq i}^{n-1} \frac{\Gamma(\beta + \beta_{i,k})}{\beta_{i,k}! \Gamma(\beta)} \frac{1}{(x_{i,n}y_{n,i})^{\beta_i,k}} \]

(6 - 9)

**6.2 \( n = 3 \)**

For \( n = 3 \), and arbitrary \( \beta \), we prove that:

**Theorem 6.2**

\[ \tilde{I}_{\beta,3} = \sum_{k=0}^{\infty} \frac{\Gamma(\beta - k)}{2^3 k! \Gamma(\beta + k)} \prod_{i<j} Q_{\beta,k}(\tau_{ij}) \]

(6-10)

In fact, for \( \beta \) integer, the sum over \( k \) is finite and reduces to \( k \leq \beta - 1 \).

The proof, rather technical, is given in appendix C. We used the Calogero equation.

**6.3 Conjecture for higher \( n \)**

Applying the recursion relations of this article, we also computed the \( n = 4 \) case for small values of \( \beta \):

\[ \tilde{I}_{2,4} = \prod_{i<j} Q_{2,0}(\tau_{ij}) \]

\[ + \frac{1}{16} Q_{2,0}(\tau_{1,2})Q_{2,0}(\tau_{1,3})Q_{2,0}(\tau_{1,4}) Q_{2,1}(\tau_{2,3})Q_{2,1}(\tau_{2,4}) + \text{sym} \]

\[ + \frac{1}{128} Q_{2,0}(\tau_{1,2})Q_{2,1}(\tau_{1,3})Q_{2,1}(\tau_{1,4})Q_{2,1}(\tau_{2,3})Q_{2,1}(\tau_{2,4}) + \text{sym} \]

(6 - 11)

and:

\[ \tilde{I}_{3,4} = 64 \prod_{i<j} Q_{3,0}(\tau_{ij}) \]

\[ + \frac{4}{3} Q_{3,0}(\tau_{1,2})Q_{3,0}(\tau_{1,3})Q_{3,0}(\tau_{1,4}) Q_{3,1}(\tau_{2,3})Q_{3,1}(\tau_{2,4})Q_{3,1}(\tau_{3,4}) + \text{sym} \]

\[ + \frac{1}{48} Q_{3,0}(\tau_{1,2})Q_{3,0}(\tau_{1,3})Q_{3,0}(\tau_{1,4}) Q_{3,2}(\tau_{2,3})Q_{3,2}(\tau_{2,4})Q_{3,2}(\tau_{3,4}) + \text{sym} \]

\[ + \ldots \]

(6-12)

Those expressions lead us to conjecture a general form in terms of Bessel polynomials:
Conjecture 6.1 We conjecture that for all \( n \) and \( \beta \), \( \hat{I}_{\beta,n} \) is of the form:

\[
\hat{I}_{\beta,n} = \sum_{\{l\}} A_{\{l\}} \prod_{i<j} Q_{\beta,l(i,j)}(\tau_{i,j})
\]

Unfortunately, we have not been able so far to determine the general form of the coefficients \( A_{\{l\}} \) for \( n > 3 \) (except \( n = 4 \) and \( \beta = 2 \)).

6.4 Symplectic case \( \beta = 2 \)

For \( \beta = 2 \), the recursion eq. (6-8), reduces to:

\[
\hat{I}_{2,n} = \Delta(Y_n)^4 \prod_{i=1}^{n-1} x_{i,n} \prod_i \frac{\partial}{\partial a_i} \left( \hat{I}_{2,n-1}(X_{n-1}, a) \right) \left. \frac{e^{\sum_i (x_i - x_n)(a_i - y_i)}}{\prod_{k=1}^{n} \prod_{i=1, i\neq k}^{n-1} (y_k - a_i)^2} \right\}_{a_i = y_i}
\]

\[
= \prod_{i=1}^{n-1} x_{i,n} y_{i,n}^2 \left( x_i - x_n - \sum_{k=1, k\neq i}^{n} \frac{2}{y_i - y_k} + \frac{\partial}{\partial a_i} \right) \hat{I}_{2,n-1}(X_{n-1}, a) \left. \right|_{a_i = y_i}
\]

\[
(6 - 14)
\]

From a recursion hypothesis, we assume that \( \hat{I}_{2,n-1}(X_{n-1}, a) \) is a polynomial in the \( \tau \)'s of the form:

\[
\hat{I}_{2,n-1}(X_{n-1}, Y_{n-1}) = \sum_{\{l\}} A_{\{l\}} \prod_{i<j} Q_{2,l(i,j)}(\tau_{i,j})
\]

where for every pair \((i, j)\) we have \( l_{i,j} \in \{0, 1\} \). We recall that:

\[
|0 > = Q_{2,0}(\tau) = \tau^2 + \tau, \quad |1 > = Q_{1,0}(\tau) = 2\tau
\]

Thus we may write:

\[
\frac{\partial}{\partial a_i} = -\frac{1}{2} \sum_{k \neq i} x_{i,k} \frac{\partial}{\partial t_{i,k}} \quad , \quad t_{i,k} = -\frac{1}{2} (x_i - x_k)(a_i - a_k)
\]

and we define the operators \( C_{i,k} \) acting on functions of the variable \( \tau_{i,k} \) such that:

\[
C_{i,k} = \frac{1}{\tau_{i,k}} - \frac{1}{2} \frac{\partial}{\partial \tau_{i,k}}
\]

and all derivatives must be eventually computed at \( t_{i,k} = \tau_{i,k} \).

Since our operators act on expressions of the form eq. (6-13), we need to compute:

\[
C_{i,j}|0 > = C_{i,j} \cdot Q_{2,0}(\tau_{i,j}) = C_{i,j}(\tau_{i,j}^2 + \tau_{i,j}) = \frac{1}{2}
\]

\[
C_{i,j}|1 > = C_{i,j} \cdot Q_{2,1}(\tau_{i,j}) = C_{i,j} \cdot 2\tau_{i,j} = 1
\]
And we may also have terms of the form $C_{i,j}C_{j,i}$, for which we have:

$$C_{i,j}C_{j,i}|0> = C_{i,j}C_{j,i} \cdot (\tau_{i,j}^2 + \tau_{i,j}) = -\frac{1}{2} , \quad C_{i,j}C_{j,i}|1> = C_{i,j}C_{j,i} \cdot \tau_{i,j} = 0 \quad (6-21)$$

Finally we have:

$$\hat{I}_{2,n} = \prod_{i=1}^{n-1} \tau_{i,n}^2 \prod_{i=1}^{n-1} \left(1 + \frac{1}{\tau_{i,n}} + \sum_{k=1, i \neq i}^{n-1} \frac{x_{i,k}}{x_{i,n}} C_{i,k} \right) \quad (6-22)$$

It is more convenient to rewrite this in terms of a Hilbert space with basis $|0> = Q_{2,0}$ and $|1> = Q_{2,1}$, and thus:

$$\hat{I}_{2,n} = \prod_{i=1}^{n-1} \left(\tau_{i,n}^2 + \tau_{i,n} + \frac{1}{2} \tau_{i,n} \sum_{k=1, i \neq i}^{n-1} \frac{y_{n,i}}{y_{k,i}} A_{i,k} \right) \quad (6-23)$$

where

$$A_{i,k} = 2\tau_{i,k}C_{i,k} \quad (6-24)$$

We have:

$$A|0> = \frac{1}{2}|1> , \quad A|1> = |1> \quad (6-25)$$

and:

$$A_{i,k}A_{k,i} = 2(A_{i,k} - 1) \quad (6-26)$$

Unfortunately we have not been able to go further with this formulation.

### 6.4.1 Triangle conjecture

We have seen that there is an operator formalism for computing angular integrals, with operators $A_{i,j}$ associated to "edges" $(i, j)$. However, it can be seen for $n = 3, 4$, that operator edges appear only in certain combinations, which involve triangles $(i, j, k)$. We thus introduce the triangles operators:

$$T_{i,j,k} = \pi_{i,j} \pi_{j,k} \pi_{k,i} \quad (6-27)$$

where $\pi_{i,j} = \pi_{j,i}$ is the projector on state $\frac{1}{2}|1> = \tau_{i,j}$:

$$\pi_{i,j} (\tau_{i,j}^2 + \tau_{i,j}) = \tau_{i,j} , \quad \pi_{i,j} \cdot \tau_{i,j} = \tau_{i,j} , \quad \pi_{i,j} = \pi_{j,i} , \quad \pi_{i,j}^2 = \pi_{i,j} \quad (6-28)$$

With this notation we have:

$$\hat{I}_{2,3} = (1 + \frac{1}{2} T_{1,2,3}). \prod_{1 \leq i < j \leq 3} |0> \quad (6-29)$$
where we recall that \( |0 >_{i,j} = \tau_{i,j}^2 + \tau_{i,j} \).

And

\[
\hat{I}_{2,4} = \left( 1 + \frac{1}{2} (T_{1,2,3} + T_{1,2,4} + T_{1,3,4} + T_{2,3,4}) \right)
+ \frac{1}{4} (T_{1,2,3}T_{1,2,4} + T_{1,2,3}T_{1,3,4} + T_{1,2,4}T_{1,3,4})
+ T_{1,2,3}T_{2,3,4} + T_{1,2,4}T_{2,3,4} + T_{1,3,4}T_{2,3,4}) \right) \cdot \prod_{1 \leq i < j \leq 4} |0 >_{i,j} \quad (6-30)
\]

We are naturally led to conjecture that:

\[
\hat{I}_{2,n} = \left( \sum_{\text{triangulations } T} C_T \prod_{T \in T} \prod_{i<j} |0 >_{i,j} \right) \quad (6-31)
\]

We have:

\[
C_\emptyset = 1 \quad , \quad C_{(i,j,k)} = \frac{1}{2} \quad , \quad C_{(i,j,k),(i,j,l)} = \frac{1}{4} \quad , \quad \ldots \quad (6-32)
\]

We have not been able so far to prove this conjecture. It is to be noted from the low values of \( n \), that triangles seem to play a role for all \( \beta \in \mathbb{N} \).

6.4.2 Additional results: determinantal recursion

Just for completeness, we give another form of the recursion eq. (6-14), in terms of determinants:

\[
\hat{I}_{2,n+1}(X_{n+1}; Y_{n+1}) = \frac{\det \left[ X - x_{n+1} - \frac{2}{\sqrt{y_n}} \right] + B + \partial_Y \right] \det(X - x_{n+1})}{\det(X - x_{n+1})} \hat{I}_{2,n}(X_n; Y_n) \quad (6-33)
\]

where

\[
\hat{I}_{2,n}(X, Y) = \frac{1}{\prod_{i<j} \tau_{i,j}^2} \hat{I}_{2,n}(X, Y) \quad (6-34)
\]

and where \( B \) is the antisymmetric matrix

\[
B_{ij} = \frac{\sqrt{2}}{y_i - y_j} \quad (6-35)
\]

and \( \partial_Y = \text{diag}(\partial_{y_1}, \ldots, \partial_{y_n}) \). This is proved by observing that the expansion of the determinant eq. (6-33) can be interpreted like a Wick’s expansion equivalent to eq. (6-14).

7 Conclusion

In this article, we have found many new relations and new representations of angular integrals.
First, we have been able to rewrite angular integrals with a complicated Haar measure, in terms of usual Lebesgue measure contour integrals. Then, we have deduced duality and recursion formulae.

This allowed us to prove Brezin-Hikami’s conjecture, and to find some explicit form for \( n = 3 \), and conjecture some explicit form in terms of Bessel polynomials for the general case.

For \( \beta = 2 \), we have simplified our recursion (computed the residues). The same method seems to be applicable for higher \( \beta \), but we have not done it in this article.

We have obtained many new forms of angular integrals, but unfortunately, this does not seem to be the end of the story. Our expressions are still not explicit enough to be useful for computing matrix integrals. The form of our expressions, strongly suggest that the kernel determinantal formulae \([25]\) in the \( \beta = 1 \) case, could be replaced by hyperdeterminantal formulae for higher \( \beta \), but this is still to be understood. The best thing, would be to get expressions with enough structure to generalize the method over integration of matrix variables of Mehta \([26]\).

Acknowledgments

We would like to thank G. Akemann, E. Brezin, P. Desrosiers, S. Hikami, A. Prats-Ferrer, J.B. Zuber, for useful and fruitful discussions on this subject. This work is partly supported by the Enigma European network MRT-CT-2004-5652, by the ANR project Géométrie et intégrabilité en physique mathématique ANR-05-BLAN-0029-01, by the Enrage European network MRTN-CT-2004-005616, by the European Science Foundation through the Misgam program, by the French and Japanese governments through PAI Sakurav, by the Quebec government with the FQRNT.

A Appendix: Polynomials of \( \tau \)

Lemma A.1 Let

\[
P_n(X, Y) = x_1x_2\cdots x_{n-1}x_n \ y_{n+1}y_{n+2}\cdots y_{2n-1}y_{2n} + y_1y_2\cdots y_{n-1}y_n \ x_{n+1}x_{n+2}\cdots x_{2n-1}x_{2n}
\]

(1-1)

We prove that \( P_n \) is a polynomial of degree \( n \) in the \( \tau \)'s, where \( \tau_{i,2n+1} = -\frac{1}{2}x_iy_i \) and \( \tau_{i,j} = -\frac{1}{2}(x_i - x_j)(y_i - y_j) \), with integer coefficients:

\[
P_n \in \mathbb{Z}[\tau]
\]

(1-2)

proof:
It clearly holds for \( n = 0 \) and \( n = 1 \). Indeed the \( n = 1 \) case reads:

\[
x_1y_2 + x_2y_1 = x_1y_1 + x_2y_2 - (x_1 - x_2)(y_1 - y_2) = 2(\tau_{1,2} - \tau_{1,3} - \tau_{2,3})
\]  

(1-3)

Assume that the lemma holds up to \( n - 1 \), and let us prove it for \( n \). In the following \( A \equiv B \) means that \( A - B \) is a polynomial in the \( \tau \)'s.

\[
P_n
\]

\[
= x_1x_2 \ldots x_{n-1}x_n y_{n+1}y_{n+2} \ldots y_{2n-1}y_{2n} + y_1y_2 \ldots y_{n-1}y_n x_{n+1}x_{n+2} \ldots x_{2n-1}x_{2n}
\]

\[
= (x_1y_{n+1} + x_{n+1}y_1)(x_2 \ldots x_{n-1}x_n y_{n+2} \ldots y_{2n-1}y_{2n} + y_2 \ldots y_{n-1}y_n x_{n+2} \ldots x_{2n-1}x_{2n})
\]

\[
- x_2 \ldots x_{n-1}x_n x_{n+1} y_{n+2} \ldots y_{2n-1}y_{2n}y_1
\]

\[
- y_2 \ldots y_{n-1}y_n y_{n+1} x_{n+2} \ldots x_{2n-1}x_{2n}x_1
\]

\[
\equiv - x_2 \ldots x_{n-1}x_n x_{n+1} y_{n+2} \ldots y_{2n-1}y_{2n}y_1
\]

\[
- y_2 \ldots y_{n-1}y_n y_{n+1} x_{n+2} \ldots x_{2n-1}x_{2n}x_1
\]

\[
(1 - 4)
\]

and then:

\[
P_n 
\]

\[
\equiv - x_2 \ldots x_{n-1}x_n x_{n+1} y_{n+2} \ldots y_{2n-1}y_{2n}y_1
\]

\[
- y_2 \ldots y_{n-1}y_n y_{n+1} x_{n+2} \ldots x_{2n-1}x_{2n}x_1
\]

\[
\equiv - (x_2y_1 + x_1y_2)(x_3 \ldots x_{n-1}x_n x_{n+1} y_{n+2} \ldots y_{2n-1}y_{2n} + y_3 \ldots y_{n-1}y_n y_{n+1} x_{n+2} \ldots x_{2n-1}x_{2n})
\]

\[
+ x_{n+1}x_1x_3 \ldots x_{n-1}x_n y_2y_{n+2} \ldots y_{2n} + y_{n+1}y_1y_3 \ldots y_n x_2x_{n+2} \ldots x_{2n}
\]

\[
(1 - 5)
\]

Repeating the same operation recursively we obtain \( \forall k \):

\[
P_n 
\]

\[
\equiv x_{n+1} \ldots x_{n+k}x_1 x_{k+2} \ldots x_n y_2 \ldots y_{k+1} y_{k+1+1} \ldots y_{2n} + y_{n+1} \ldots y_{n+k} y_1 y_{k+2} \ldots y_n x_2 \ldots x_{k+1} x_{k+n+1} \ldots x_{2n}
\]

\[
(1 - 6)
\]

In particular for \( k = n - 2 \) we find:

\[
P_n 
\]

\[
\equiv x_{n+1} \ldots x_{2n-2} x_1 x_n y_2 \ldots y_{n-1} y_{2n-1} y_{2n}
\]

\[
+ y_{n+1} \ldots y_{2n-2} y_1 y_n y_2 \ldots x_{n-1} x_{2n-1} x_{2n}
\]

\[
\equiv (x_1y_{2n-1} + x_{2n-1}y_1)(x_{n+1} \ldots x_{2n-2} x_n y_2 \ldots y_{n-1} y_{2n}
\]

\[
+ y_{n+1} \ldots y_{2n-2} y_1 y_n x_2 \ldots x_{n-1} x_{2n})
\]

\[
- x_n \ldots x_{2n-1} y_1y_2 \ldots y_{n-1} y_{2n} - y_n \ldots y_{2n-1} x_1x_2 \ldots x_{n-1} x_{2n}
\]
and we repeat the same operations:

\[
P_n \equiv -x_1 x_2 \ldots x_{n-1} x_{2n} \equiv -(x_n y_1 + x_1 y_n) (x_{n+1} \ldots x_{2n-1} y_2 \ldots y_{n-1} y_{2n} + y_{n+1} \ldots y_{2n-1} x_2 \ldots x_{n-1} x_{2n}) + x_1 x_{n+1} \ldots x_{2n-1} y_2 \ldots y_n y_{2n} + y_1 y_{n+1} \ldots y_{2n-1} x_2 \ldots x_n x_{2n}
\]

(1-8)

and once more

\[
P_n \equiv x_1 x_{n+1} \ldots x_{2n-1} y_2 \ldots y_n y_{2n} + y_1 y_{n+1} \ldots y_{2n-1} x_2 \ldots x_n x_{2n}
\]

(1-9)

Therefore \( P_n \equiv -P_n \), i.e. \( P_n \) is a polynomial in the \( \tau \)'s.

\[\Box\]

**Lemma A.2** Let

\[
P_{\alpha, \beta}(X, Y) = \prod_{i=1}^{n} x_i^{\alpha_i} y_i^{\beta_i} + \prod_{i=1}^{n} x_i^{\beta_i} y_i^{\alpha_i}, \quad \sum_{i} \alpha_i = \sum_{i} \beta_i = d \quad (1-10)
\]

We prove that \( P_{\alpha, \beta} \) is a polynomial of degree \( d \) in the \( \tau \)'s, with integer coefficients:

\[
P_n \in \mathbb{Z}[\tau] \quad (1-11)
\]

**proof:**

We proceed by recursion on the total degree \( d = \sum_i \alpha_i = \sum_i \beta_i \). The lemma clearly holds for \( d = 0 \) and \( d = 1 \).

Assume \( d \geq 2 \) and that the lemma holds up to \( d - 1 \). We will prove it for \( d \).

- if there exists \( i \) such that \( \alpha_i \beta_i > 0 \), then \( P_{\alpha, \beta} \) is the factor of \( \tau_{i,n+1} \) times \( P_{\alpha', \beta'} \) of smaller degree, and from the recursion hypothesis it holds.

- assume that \( \forall i, \alpha_i \beta_i = 0 \). Since \( d \geq 2 \), there must exist some \( i \) such that \( \alpha_i \geq 1 \) and some \( j \) such that \( \beta_j \geq 1 \). Let us choose \( k \) and \( l \) such that:

\[
\alpha_k = \max_i \{\alpha_i\} \geq 1, \quad \beta_l = \max_i \{\beta_i\} \geq 1 \quad (1-12)
\]

We have \( k \neq l \).
If $\alpha_k = \beta_l = 1$, then we can apply lemma A.1 and thus the lemma is proved for that case.

- Therefore, we now assume that $\alpha_k\beta_l \geq 2$, and with no loss of generality we may assume that $\alpha_k \geq 2$. We write:

$$P_n = x_1^{\alpha_1} \cdots x_n^{\alpha_n} y_1^{\beta_1} \cdots y_n^{\beta_n} + x_1^{\beta_1} \cdots x_n^{\beta_n} y_1^{\alpha_1} \cdots y_n^{\alpha_n}$$

$$= (x_k y_l + x_l y_k) (x_1^{\alpha_1} \cdots x_k^{\alpha_k-1} \cdots x_n^{\alpha_n} y_1^{\beta_1} \cdots y_l^{\beta_l-1} \cdots y_n^{\beta_n})$$

$$+ y_1^{\alpha_1} \cdots y_k^{\alpha_k-1} \cdots y_n^{\alpha_n} x_1^{\beta_1} \cdots x_l^{\beta_l-1} \cdots x_n^{\beta_n}$$

$$- x_1^{\alpha_1} \cdots x_k^{\alpha_k-1} x_l^{\beta_l+1} \cdots x_n^{\alpha_n} y_1^{\beta_1} \cdots y_l^{\beta_l-1} y_k^{\beta_k+1} \cdots y_n^{\beta_n}$$

$$- y_1^{\alpha_1} \cdots y_k^{\alpha_k-1} y_l^{\beta_l+1} \cdots y_n^{\alpha_n} x_1^{\beta_1} \cdots x_l^{\beta_l-1} x_k^{\beta_k+1} \cdots x_n^{\beta_n}$$

$$\equiv - x_k y_l (x_1^{\alpha_1} \cdots x_k^{\alpha_k-2} x_l^{\beta_l+1} \cdots x_n^{\alpha_n} y_1^{\beta_1} \cdots y_l^{\beta_l-1} y_k^{\beta_k+1} \cdots y_n^{\beta_n})$$

$$+ y_1^{\alpha_1} \cdots y_k^{\alpha_k-2} y_l^{\beta_l+1} \cdots y_n^{\alpha_n} x_1^{\beta_1} \cdots x_l^{\beta_l-1} x_k^{\beta_k+1} \cdots x_n^{\beta_n})$$

$$(1 - 13)$$

From the recursion hypothesis, the RHS is a polynomial in the $\tau$’s, and thus we have proved the lemma.

□

**Lemma A.3** Let $P$ be a polynomial of $2n+2$ variables $x_1, \ldots, x_n, x_{n+1}, y_1, \ldots, y_n, y_{n+1}$, with the following properties:

- $P$ is invariant by translations $\forall i, \ x_i \to x_i + \delta x$, $y_i \to y_i + \delta y$,
- $P$ is invariant under $\forall i, \ x_i \to \lambda x_i$, $y_i \to \frac{1}{\lambda} y_i$,
- $P$ is symmetric in the exchange $X \leftrightarrow Y$.

Then $P$ is a polynomial of the $\tau_{i,j}$’s.

**proof:**

Because of invariance by translation, we can always assume that $x_{n+1} = y_{n+1} = 0$. Then, the other properties imply that $P$ is a linear combination of monomials of the type $P_{\alpha,\beta}(X,Y)$ of Lemma A.2

□

**B Appendix: Loop equations**

Loop equations for matrix models have been studied for a long time [27]. Loop equations (sometimes called Ward identities or Schwinger-Dyson equations) for $\beta$ ensembles can be found for instance in [12, 33, 19, 20, 21, 6]. Here, we summarize the method.
• 1-matrix model in eigenvalue representation, for arbitrary $\beta$:

Consider the integral:

$$ Z = \int d\lambda_1 \ldots d\lambda_n e^{-\sum_i V(\lambda_i)} \prod_{i < j} (\lambda_j - \lambda_i)^{2\beta} \quad (2-1) $$

If we make an infinitesimal local change of variable $\lambda_i \to \lambda_i + \epsilon \lambda_i^k + O(\epsilon^2)$, we find:

$$ Z = (1 + O(\epsilon^2)) \int d\lambda_1 \ldots d\lambda_n \prod_i (1 + \epsilon k \lambda_i^{k-1}) e^{-\sum_i V(\lambda_i)} \prod_i (1 - \epsilon \lambda_i^k V'(\lambda_i)) \prod_{i < j} (\lambda_j - \lambda_i)^{2\beta} \prod_{i < j} (1 + 2\beta \epsilon \frac{\lambda_i^k - \lambda_j^k}{\lambda_i - \lambda_j}) \quad (2-2) $$

i.e., by considering the term linear in $\epsilon$:

$$ 0 = \left\langle \sum_i k \lambda_i^{k-1} + \beta \sum_{l=0}^{k-1} \sum_{i \neq j} \lambda_i^l \lambda_j^{k-1-l} - \sum_i \lambda_i^k V'(\lambda_i) \right\rangle \quad (2-3) $$

It can be written collectively by summing over $k$ with $1/x^{k+1}$, this is equivalent to consider a local change of variable $\lambda_i \to \lambda_i + \epsilon \frac{1}{x - \lambda_i} + O(\epsilon^2)$, and we write $\omega(x) = \sum_i \frac{1}{x - \lambda_i}$:

$$ 0 = \left\langle -\omega'(x) + \beta (\omega(x)^2 + \omega'(x)) - \sum_i \frac{V'(\lambda_i)}{x - \lambda_i} \right\rangle \quad (2-4) $$

i.e.

$$ 0 = -\left\langle \text{Tr} \frac{V'(M)}{x - M} \right\rangle + \beta \left\langle \text{Tr} \frac{1}{x - M} \text{Tr} \frac{1}{x - M} \right\rangle + (\beta - 1) \frac{\partial}{\partial x} \left\langle \text{Tr} \frac{1}{x - M} \right\rangle \quad (2-5) $$

• 2-matrix model for $\beta = 1/2, 1, 2$:

Similarly if we consider a 2-matrix model:

$$ Z = \int dM_1 dM_2 e^{-\text{Tr} (V_1(M_1) + V_2(M_2) - M_1 M_2)} \quad (2-6) $$

again we make a local change of variable $M_1 \to M_1 + \epsilon \frac{1}{x - M_1} A + O(\epsilon^2)$. The Jacobian of this change of variable is computed as a split rule (cf []), it can be computed for each of the 3 ensembles $\beta = 1/2, 1, 2$ and is worth:

$$ dM_1 \to dM_1 \left( 1 + \epsilon \beta \text{Tr} \frac{1}{x - M_1} \text{Tr} A \frac{1}{x - M_1} + \epsilon (\beta - 1) \frac{\partial}{\partial x} \text{Tr} A \frac{1}{x - M_1} + O(\epsilon^2) \right) \quad (2-7) $$

Thus we find:

$$ 0 = -\left\langle \text{Tr} (V_1(M_1) - M_2) \frac{1}{x - M_1} \right\rangle + \beta \left\langle \text{Tr} \frac{1}{x - M_1} \text{Tr} A \frac{1}{x - M_1} \right\rangle $$
\[ +(\beta - 1) \frac{\partial}{\partial x} \left\langle \text{Tr} \ A \frac{1}{x - M_1} \right\rangle \]  \hspace{1cm} (2-8)

- Without a definition of a 2-matrix integral for arbitrary \( \beta \), it is not possible to find the loop equation for any \( \beta \). However, we see that equation eq. (2-8) is valid for the 2-matrix model for \( \beta = 1/2, 1, 2 \), and is valid for the 1-matrix eigenvalue model for any \( \beta \). Therefore it is natural to take it as a definition of the 2-matrix model for arbitrary \( \beta \).

C Appendix: Proof \( \ n = 3 \)

C.1 BESSEL ZOOLOGY

We define the functions

\[ Q_{\beta} (x) = \sum_{l=0}^{\infty} (-)^l \frac{\Gamma (\beta + l)}{\Gamma (\beta - l)} \frac{2^{-l}}{l!} x^{\beta - l} \] \hspace{1cm} (3-1)

We have

\[ 2x^2 Q_{\beta}' (x) - 2\beta x Q_{\beta} (x) = -\sum_{l=1}^{\infty} (-)^l \frac{\Gamma (\beta + l)}{\Gamma (\beta - l)} \frac{2^{-l+1}}{(l-1)!} x^{\beta - l+1} \]
\[ x^2 Q_{\beta}'' (x) - 2\beta x Q_{\beta}' (x) + 2\beta Q_{\beta} (x) = -\sum_{l=0}^{\infty} (-)^l \frac{\Gamma (\beta + l + 1)}{\Gamma (\beta - l - 1)} \frac{2^{-l}}{l!} x^{\beta - l} \] \hspace{1cm} (3-2)

Changing \( l \) into \( l + 1 \) in (3-2) we obtain the differential equation

\[ x^2 Q_{\beta}'' (x) - 2x (\beta - x) Q_{\beta}' (x) + 2\beta (1 - x) Q_{\beta} (x) = 0 \] \hspace{1cm} (3-3)

We define the functions

\[ Q_{\beta,k} (x) = (-2)^k x^{\beta-k} \left( x^2 \frac{d}{dx} \right)^k \left( \frac{Q_{\beta} (x)}{x^\beta} \right) \] \hspace{1cm} (3-4)
\[ Q_{\beta,0} (x) = Q_{\beta} (x) \] \hspace{1cm} (3-5)

that is

\[ Q_{\beta,k} (x) = \sum_{l=0}^{\infty} (-)^{l+k} \frac{\Gamma (\beta + l + k)}{\Gamma (\beta - l - k)} \frac{2^{-l}}{l!} x^{\beta - l - k} \] \hspace{1cm} (3-6)

From (3-1) we obtain the recurrence

\[ Q_{\beta,k} (x) = 2(\beta - k + 1) Q_{\beta,k-1} (x) - 2x Q_{\beta,k-1}' (x) \] \hspace{1cm} (3-7)

For instance

\[ Q_{\beta,1} (x) = 2\beta Q_{\beta,0} (x) - 2x Q_{\beta,0}' (x) \] \hspace{1cm} (3-8)
and
\[ Q_{\beta,2}(x) = 2(\beta - 1) Q_{\beta,1}(x) - 2x Q'_{\beta,1}(x) \]  
\[ Q_{\beta,2}(x) = 4x^2 Q''_{\beta,0}(x) - 8x(\beta - 1) Q'_{\beta,0}(x) + 4\beta(\beta - 1) Q_{\beta,0}(x) \]

Thus, we have, from 3-8 and 3-10, the expressions \( Q'_{\beta,0}(x) \) and \( Q''_{\beta,0}(x) \) in terms of \( Q_{\beta,1}(x) \) and \( Q_{\beta,2}(x) \). Equation 3-3 becomes
\[ Q_{\beta,2}(x) + 4(1 - x) Q_{\beta,1}(x) - 4\beta(\beta - 1) Q_{\beta,0}(x) = 0 \]

From 3-11 by derivatives \( \frac{d}{dx} \) and recurrence, it is easy to show that
\[ Q_{\beta,k+2}(x) + 4(k + 1 - x) Q_{\beta,k+1}(x) - 4[\beta(\beta - 1) - k(k + 1)] Q_{\beta,k}(x) = 0 \]

C.2 CALOGERO N=3

We consider the Calogero differential operator
\[ H_{\text{Calogero}} = \sum_{i=1}^{3} \frac{d^2}{dx_i^2} + 2\beta \sum_{i<j} \frac{1}{x_i - x_j} \left( \frac{d}{dx_i} - \frac{d}{dx_j} \right) \]

and we look for solutions
\[ H_{\text{Calogero}} \Phi(x_i, y_i) = \left( \sum_i y_i^2 \right) \Phi(x_i, y_i) \]

where the solutions \( \Phi(x_i, y_i) \) have a certain number of symmetry properties described somewhere else. We write
\[ \Phi(x_i, y_i) = f(x_i, y_i) e^{\sum_{i=1}^{3} x_i y_i} \]

so that the equations 3-13 and 3-14 become
\[ D = \sum_{i=1}^{3} \frac{d^2}{dx_i^2} + 2\beta \sum_{i<j} \frac{1}{x_i - x_j} \left( \frac{d}{dx_i} - \frac{d}{dx_j} + y_i - y_j \right) + 2 \sum_{i=1}^{3} y_i \frac{d}{dx_i} \]

and
\[ D f(x_i, y_i) = 0 \]
Let us introduce the variables

\[ a = \frac{1}{2} (x_1 - x_2) \ (y_1 - y_2) = (x_1 - x_2) \ Y_{12} \]  
\[ b = \frac{1}{2} (x_1 - x_3) \ (y_1 - y_3) = (x_1 - x_3) \ Y_{13} \]  
\[ c = \frac{1}{2} (x_2 - x_3) \ (y_2 - y_3) = (x_2 - x_3) \ Y_{23} \]

where

\[ Y_{ij} = -Y_{ji} \]

and we look for solutions of the type \( f (a, b, c) \). We have

\[ \frac{df}{dx_1} = Y_{12} \ f'_a + Y_{13} \ f'_b \]  
\[ \frac{df}{dx_2} = Y_{21} \ f'_a + Y_{23} \ f'_c \]  
\[ \frac{df}{dx_3} = Y_{31} \ f'_b + Y_{32} \ f'_c \]

and

\[ \frac{d^2 f}{dx_1^2} = Y_{12}^2 \ f''_a + 2Y_{12}Y_{13} \ f''_{ab} + Y_{13}^2 \ f''_b \]  
\[ \frac{d^2 f}{dx_2^2} = Y_{21}^2 \ f''_a + 2Y_{21}Y_{23} \ f''_{ac} + Y_{23}^2 \ f''_c \]  
\[ \frac{d^2 f}{dx_3^2} = Y_{31}^2 \ f''_b + 2Y_{31}Y_{32} \ f''_{bc} + Y_{32}^2 \ f''_c \]

The equations \( 3 \text{-}16 \) and \( 3 \text{-}17 \) become

\[ D f (a, b, c) = D_1 f (a, b, c) + D_2 f (a, b, c) = 0 \]  
\[ D_1 f (a, b, c) = Y_{12}^2 \left[ 2f''_a + 4 \left( \frac{\beta}{a} + 1 \right) f'_a + 4 \frac{\beta}{a} f \right] + \text{circ.perm.} \]  
\[ D_2 f (a, b, c) = 2Y_{12}Y_{13} \left[ f''_{ab} + \frac{\beta}{a} f'_b + \frac{\beta}{b} f'_a \right] + \text{circ.perm.} \]

We now try the functions

\[ f (a, b, c) = \frac{Q_{\beta,k} (a)}{a^{23}} \frac{Q_{\beta,k} (b)}{b^{23}} \frac{Q_{\beta,k} (c)}{c^{23}} = \frac{\{k, k, k\}}{(abc)^{23}} \]

where \( Q_{\beta,k} (x) \) are defined in \( 3 \text{-}4 \text{-}3 \text{-}5 \) and \( 3 \text{-}6 \). We consider

\[ f (a) = \frac{Q_{\beta,k} (a)}{a^{23}} \]  
\[ f (a, b, c) = \frac{Q_{\beta,k} (a)}{a^{23}} \frac{Q_{\beta,k} (b)}{b^{23}} \frac{Q_{\beta,k} (c)}{c^{23}} = \frac{\{k, k, k\}}{(abc)^{23}} \]
we have

\[ 2 f'_a + 2 \frac{\beta}{a} f = \frac{2a Q_{\beta,k} (a) - 2\beta Q_{\beta,k} (a)}{a^{2\beta+1}} = -2k Q_{\beta,k} (a) + Q_{\beta,k+1} (a) \]  

(3-33)

By derivation we obtain

\[ 2f''_a + 2 \frac{\beta}{a} f'_a - 2 \frac{\beta}{a^2} f = \frac{1}{a^{2\beta+2}} \left[ \frac{1}{2} Q_{\beta,k+2} (a) + (\beta + 2k + 2) Q_{\beta,k+1} (a) \right] \]  

(3-34)

so that

\[ 2f''_a + 4 \frac{\beta}{a} f'_a + 2 \frac{2 \beta (\beta - 1)}{a^2} f = \frac{1}{a^{2\beta+2}} \left[ \frac{1}{2} Q_{\beta,k+2} (a) + 2(k+1) Q_{\beta,k+1} (a) \right] \]  

(3-35)

\[ 2f''_a + 4 \frac{\beta}{a} f'_a = \frac{1}{a^{2\beta+2}} \left[ \frac{1}{2} Q_{\beta,k+2} (a) + 2(k+1) Q_{\beta,k+1} (a) \right] \]  

(3-36)

Finally we obtain

\[ 2f''_a + 4(\frac{\beta}{a} + 1) f'_a + 4 \frac{\beta}{a} f = \frac{1}{2a^{2\beta+2}} \left[ Q_{\beta,k+2} (a) + 4(k+1-a) Q_{\beta,k+1} (a) \right] \]  

(3-37)

Now, we use the recurrence relation (3-12) and get the simple result

\[ 2f''_a + 4(\frac{\beta}{a} + 1) f'_a + 4 \frac{\beta}{a} f = -\frac{4k}{a^{2\beta+1}} Q_{\beta,k} (a) \]  

(3-38)

We just proved that

\[ D_1 \left\{ \frac{k,k,k}{(abc)^{2\beta}} \right\} = -4k \left( \frac{Y^2_{12}}{a} + \frac{Y^2_{31}}{b} + \frac{Y^2_{23}}{c} \right) \frac{k,k,k}{(abc)^{2\beta}} \]  

(3-39)

We further transform the result (3-39). We have

\[ \frac{Y^2_{12}}{a} = \frac{Y_{12}}{(x_1 - x_2)} \frac{Y_{12}}{\Delta(x)} (x_1 - x_3) \]  

(3-40)

\[ \frac{Y^2_{12}}{a} = \frac{Y_{12}}{\Delta(x)} [F - (x_1 - x_2)^2] \]  

(3-41)

where

\[ \Delta(x) = (x_1 - x_2) \]  

(3-42)

\[ F = x_1^2 + x_2^2 + x_3^2 - x_1 x_2 - x_1 x_3 - x_2 x_3 \]  

(3-43)

By circular permutation we also have

\[ \frac{Y^2_{31}}{b} = \frac{Y^2_{31}}{\Delta(x)} [F - (x_3 - x_1)^2] \]  

(3-44)

\[ \frac{Y^2_{23}}{c} = \frac{Y^2_{23}}{\Delta(x)} [F - (x_2 - x_3)^2] \]  

(3-45)
We note that in 3-39 the quantity $F$ disappear since

$$Y_{12} + Y_{23} + Y_{31} = 0 \quad (3-46)$$

We may write now

$$D_1 \left\{ \frac{k, k, k}{(abc)^{2\beta}} \right\} = \frac{4k}{\Delta(x)} \left[ (x_1 - x_2) a + \text{circ.perm.} \right] \left\{ \frac{k, k, k}{(abc)^{2\beta}} \right\} \quad (3-47)$$

We now consider

$$D_2 \left\{ \frac{k, k, k}{(abc)^{2\beta}} \right\} \quad (3-48)$$

Using

$$f(a, b, c) = f(a) f(b) f(c) \quad (3-49)$$

we have

$$f_a^\omega (a, b, c) + \frac{\beta}{a} f_b^\omega (a, b, c) + \frac{\beta}{b} f_c^\omega (a, b, c) = \left[ \left( f_a^\omega (a) + \frac{\beta f(a)}{a} \right) \left( f_b^\omega (b) + \frac{\beta f(b)}{b} \right) \right] f(c) \quad (3-50)$$

but in 3-30 the term $\frac{\beta^2}{ab} f(a) f(b) f(c)$ disappears since

$$\frac{Y_{12} Y_{13}}{ab} + \text{circ.perm.} = \frac{x_2 - x_3}{\Delta(x)} + \text{circ.perm.} = 0 \quad (3-51)$$

Then, from 3-33 we get

$$= \left[ 2Y_{12} Y_{13} \frac{k Q_{\beta, k}(a) + \frac{\beta}{k} Q_{\beta, k+1}(a)}{\Delta(x) (abc)^{2\beta}} \frac{k Q_{\beta, k}(b) + \frac{\beta}{b} Q_{\beta, k+1}(b)}{\Delta(x) (abc)^{2\beta}} \frac{Q_{\beta, k}(c)}{\Delta(x) (abc)^{2\beta}} \right] + \text{circ.perm.} \quad (3-52)$$

Again, the term containing $Q_{\beta, k} (a)$ $Q_{\beta, k} (b)$ $Q_{\beta, k} (c)$ disappears by 3-51. We write

$$D_2 \left\{ \frac{k, k, k}{(abc)^{2\beta}} \right\} = \frac{1}{\Delta(x)} \frac{1}{(abc)^{2\beta}} \left[ (x_2 - x_3) \left[ \frac{1}{2} \left\{ k + 1, k + 1, k \right\} \right. \right.$$

$$\left. + k \left\{ k + 1, k, k \right\} + k \left\{ k, k + 1, k \right\} \right] + \text{circ.perm.} \quad (3-53)$$

We note that

$$(x_2 - x_3) \left[ \left\{ k + 1, k, k \right\} + \left\{ k + 1, k, k \right\} + \left\{ k, k + 1, k \right\} \right] + \text{circ.perm.} = 0 \quad (3-54)$$

so that

$$D_2 \left\{ \frac{k, k, k}{(abc)^{2\beta}} \right\} = \frac{1}{\Delta(x)} \frac{1}{(abc)^{2\beta}} \left[ (x_2 - x_3) \left[ \frac{1}{2} \left\{ k + 1, k + 1, k \right\} \right. \right.$$

$$\left. - k \left\{ k, k, k \right\} \right] + \text{circ.perm.} \quad (3-55)$$
We now collect $D_1$ and $D_2$. From 3-28, 3-31, 3-47 and 3-55, we obtain

$$D \left\{ \{k, k, k\} \right\}_{(abc)^{2\beta}} = \frac{1}{\Delta(x)} \frac{1}{(abc)^{2\beta}} \left[ (x_2 - x_3) \left[ 4kc \{k, k, k\} + \frac{1}{2} \{k + 1, k + 1, k\} - k \{k, k, k + 1\} \right] + \text{circ.perm.} \right]$$

(3-56)

Again,

$$(x_2 - x_3) \{k, k, k\} + \text{circ.perm.} = 0$$

(3-57)

so that

$$D \left\{ \{k, k, k\} \right\}_{(abc)^{2\beta}} = \frac{1}{\Delta(x)} \frac{1}{(abc)^{2\beta}} \left[ (x_2 - x_3) \left[ \frac{1}{2} \{k + 1, k + 1, k\} - k \{k, k, k + 1\} \right] + \text{circ.perm.} \right]$$

(3-58)

We now use equation (10) and write

$$D \left\{ \{k, k, k\} \right\}_{(abc)^{2\beta}} = \frac{1}{\Delta(x)} \frac{1}{(abc)^{2\beta}} \left[ (x_2 - x_3) \left[ -4k (\beta - k) (\beta + k - 1) \{k, k, k - 1\} \right] + \text{circ.perm.} \right]$$

(3-59)

Consequently, we obtain the remarkable result

$$D \left[ \frac{\Gamma (\beta - k)}{\Gamma (\beta + k)} \frac{1}{8^k k!} \left\{ \frac{k, k, k}{(abc)^{2\beta}} \right\} \right] = \frac{1}{2\Delta(x)} \frac{1}{(abc)^{2\beta}} \left[ (x_2 - x_3) \left[ -\frac{\Gamma (\beta - k)}{\Gamma (\beta + k)} \frac{1}{8^k k!} \left\{ k + 1, k + 1, k \right\} - k \{k, k, k - 1\} \right] + \text{circ.perm.} \right]$$

(3-60)

Clearly enough, we define for $\beta$ not integer

$$f (abc) = \sum_{k=0}^{\infty} \frac{\Gamma (\beta - k)}{\Gamma (\beta + k)} \frac{1}{8^k k!} \left\{ k, k, k \right\}_{(abc)^{2\beta}}$$

(3-61)

then,

$$D f (abc) = 0 + \text{circ.perm.}$$

(3-62)

Now, if $\beta$ is an integer

$$Q_{\beta, k \geq \beta} (x) = 0$$

(3-63)

and we define

$$f (abc) = \sum_{k=0}^{\beta-1} \frac{\Gamma (\beta - k)}{\Gamma (\beta + k)} \frac{1}{8^k k!} \left\{ k, k, k \right\}_{(abc)^{2\beta}}$$

(3-64)

so that

$$D f (abc) = 0 + \text{circ.perm.}$$

(3-65)
We proved that a solution to 3-14 is
\[ \Phi (x_i, y_i) = \left[ \sum_{k=0}^{\infty \text{ or } \beta - 1} \frac{\Gamma(\beta - k)}{\Gamma(\beta + k)} \frac{1}{8^k k!} \{k, k, k\} (abc)^{2\beta} \right] e^{\sum_{i=1}^{3} x_i y_i} \] (3-66)

\[ H_{\text{Calogero}} \Phi (x_i, y_i) = 0 \] (3-67)

where \( H_{\text{Calogero}} \) is given in 3-13
