SUMMARY

This paper presents the software package SYMORO+ for the automatic symbolic modelling of robots. This package permits to generate the direct geometric model, the inverse geometric model, the direct kinematic model, the inverse kinematic model, the dynamic model, and the inertial parameters identification models.

The structure of the robots can be serial, tree structure or containing closed loops. The package runs on Sun stations and PC computers, it has been developed under MATHEMATICA and C language. In this paper we give an overview of the algorithms used in the different models, the computational cost of the dynamic models of the PUMA robot are given.

KEYWORDS: Symbolic calculation, robots, modelling, identification, kinematic, dynamic, simulation.

1. INTRODUCTION

Many works have been devoted to the automatic generation of the symbolic modelling of robots. Most of these works were interested in the generation of some models or more especially in the dynamic model only. SYMORO+ generates almost all the symbolic models needed in the simulation, control, identification, and design of robots. This package is the result of the research work of the robotics team of the "Laboratoire d'Automatique de Nantes", in the field of modelling, control and identification of robots.
The programs generating the different models are developed using MATHEMATICA [1]. A graphic interface, written in language C, is developed such that the user can define his robot or the desired model using recent stations environment. The main interface page is seen in figure 1, on which we distinguish the parameters of the robot and the following main menus: Robot, Geometric, Kinematic, Dynamic, Identification, Optimizer.

The functions and models corresponding to these menus are given in table 1.

The paper is organized as follows: Section 2 gives the parameters needed to define a robot, then sections 3, …, 7 present the different models which can be generated by SYMORO+, an idea will be given to describe the algorithms which are used in generating the different models.

Figure 1: Main page of SYMORO+
2- ROBOT DESCRIPTION

The definition of a robot is carried out using the menu **Robot**. The software package SYMORO+ can treat serial, tree structure or closed loop robots. The description of the geometry of the robot is carried out using the notations of Khalil and Kleinfinger [2]. At first the number of moving links (N_{L}), the number of joints (N_{J}) and the type of structure (serial, tree structure or closed) must be given. The following three sets of parameters (figure 1) are then defined either numerically or symbolically:

### 2.1 The geometric parameters

These parameters define the kinematic of the structure, the type of joints and the location of the link frames with respect to its antecedent [2]. The coordinate frame j is assigned fixed with respect to link j. The z\_j axis is along the axis of joint j, the x\_j axis is along the common perpendicular of z\_j and one of the following axis on the same link. The geometry of the robot is defined by the following parameters (for j=1,…,N_f):

**Table 1**: Functions and models of the menus of SYMORO+
- $\gamma_j$, $b_j$, $\alpha_j$, $d_j$, $\theta_j$, $r_j$ defining frame $j$ with respect to its antecedent frame $a(j)$, figure 2, in serial robots $\gamma_j$, $b_j$ are equal to zero. It is to be noted that the joint variable $q_j$ is equal to $\theta_j$ if $j$ is rotational and equal to $r_j$ for $j$ translational,
- $\sigma_j$ defining the type of joint $j$. $\sigma_j = 0$ for $j$ rotational, $\sigma_j = 1$ for $j$ translational,
- the antecedent frames $a(j)$,
- $\mu_j$ indicates if the joint $j$ is motorized (active) or not (passive). In open loop robots (serial or tree structure robots) all the joints are supposed active.

It is to be noted that the number of frames $N_f$ in serial or tree structure robot is equal to the number of moving links $N_L$. In the case of closed loop robot we suppose each closed loop opened in one of its passive joint to construct an equivalent tree structure, then we add two frames on one of the links surrounding the opened joints. If the number of the opened joint is $k$ the number of the corresponding additional frames will be $k$ and $k+B$, these two frames are aligned but their antecedent frames are not the same (figure 3). Thus in the case of closed loop robots

$$N_f = N_L + 2B$$

where $B = N_j - N_L = \text{number of closed loops}$.

### 2.2 Dynamic parameters

These parameters are composed of inertial and friction parameters. For each link the following parameters have to be defined:

$$[XX_j, XY_j, XZ_j, YY_j, YZ_j, ZZ_j, MX_j, MY_j, MZ_j, M_j, I_{aj}], \text{ and } [F_{vj}, F_{sj}]$$

where:

- $(XX_j, ..., ZZ_j)$ are the elements of the inertia matrix $JJ_j$, defining the inertia of link $j$, around the origin of frame $j$,
- $(MX_j, MY_j, MZ_j)$ are the elements of $JMS_j$ defining the first moments of link $j$,
- $M_j$ the mass of link $j$,
- $I_{aj}$ inertia of motor $j$ referred to the joint side.

$F_{vj}$, $F_{sj}$ are the viscous and static friction coefficients of joint $j$.

### 2.3 General parameters

The following parameters can also be defined.

- The location of the base of the robot with respect to a general fixed frame (matrix $Z$).
- Joint velocities ($QP_j$) and accelerations ($QDP_j$).
- External forces of each link on the environment ($FX_j, FY_j, FZ_j$)
- External moments of each link on the environment ($Cx_j, CY_j, CZ_j$).
- The speed and the acceleration of the base of the robot.
- The acceleration of gravity: $g = [G1 \ G2 \ G3 ]^T$. 

-4-
3. THE GEOMETRIC MODELS

The following models can be obtained under menu Geometric.

3.1 The direct geometric model: The direct geometric model, gives the position and orientation of the end effector as function of the motorized joints variables. It can be obtained by the multiplication of the transformation matrices along the path between the base of the robot and the terminal link. A frame $j$ will be defined with respect to frame $r$, by the following (4x4) transformation matrix:

$$
^rT_j = \begin{bmatrix}
^rA_j & ^rP_j \\
0 & 0 & 0 & 1
\end{bmatrix}
$$

(1-a)

where

* $^rA_j$ defines the orientation of frame $j$ with respect to frame $r$.
* $^rP_j$ defines the position of the origin of frame $j$ with respect to frame $i$.

The frame $j$ coordinate will be defined with respect to frame $i$, with $i = a(j)$, by the following (4x4) matrix:

$$
^iT_j = \begin{bmatrix}
C\gamma_jC\theta_j - S\gamma_jC\alpha_jS\theta_j -C\gamma_jS\theta_j - S\gamma_jC\alpha_jC\theta_j + S\gamma_jS\alpha_j + d_jC\gamma_j + r_jS\gamma_jS\alpha_j \\
S\gamma_jC\theta_j + C\gamma_jC\alpha_jS\theta_j -S\gamma_jS\theta_j + C\gamma_jC\alpha_jC\theta_j - C\gamma_jS\alpha_j + d_jS\gamma_j - r_jC\gamma_jS\alpha_j \\
S\alpha_jS\theta_j -S\alpha_jC\theta_j + C\alpha_j + r_jC\alpha_j + b_j \\
0 & 0 & 0 & 1
\end{bmatrix}
$$

(1-b)

where:

* $S= \sin$, $C= \cos$,

In the case of open loop robots the direct geometric model is defined by the transformation matrix of the terminal link referred to the base. In the case of closed loop robots the constraint equations defining the relation between the passive joint variables, in the path between the terminal link and the base, and the motorized joints outside this path can be obtained by solving the geometric constraint equations (section 3.4), in order to obtain the location of the end effector as function of motorized joints only.

3.2 Fast geometric model

This function gives the transformation matrix between two frames in customized form, using intermediate variables in order to minimize its calculation cost.
3.3 The inverse geometric model

The inverse geometric model is the closed form solution giving all the configurations of the robot corresponding to a given location of the end effector. In our software package three methods are used:

* The first is derived from the work presented in [3, 4]. This method gives the solution of six degrees of freedom robot provided that one of the following conditions is verified:
  - the robot contains three translational joints.
  - the robot has three rotational joints defining a spherical joint (their axes are intersecting).

* The second method is derived from the work given in [5,6]. This method can provide the solution of most of the current industrial robots.

* The third method is derived from the general method of Raghavan and Roth [7, 8], where the solution of one variables is given as a polynomial equation of degree 16 at most, then the other variables can be obtained.

In the case of closed loop robots, the programs (Pieper, Paul, or general method) give the solution of the joints on the direct path between the base of the robot and the end effector. To get the values of the motorized joint positions outside this path the geometric constraint equations of the loops must be resolved, as seen in the following section.

![Figure 2: Definition of link frames.](image-url)
3.4 Geometric constraint equations of loops

The direct and inverse geometric models of closed loop robots can be considered as the direct and inverse geometric robot of the serial path from the base to the terminal link plus the solution of the geometric constraint equations of the closed loops of the robot. We make use of the method developed in [4]. The solution is ensured analytically for each closed loop with less than five passive joints. The geometric constraint equations can be obtained by solving the transformation matrix along the loop (figure 3) which is equal to the identity matrix:

\[ B_{T_i} \ldots j_{T_{k+B}} = I_4 \]  

with \( I_4 \) is the 4x4 identity matrix.

4. THE KINEMATIC MODELING

The direct kinematic model defines the velocity of the end effector as function of the joint velocities. It can be written as:

\[
\begin{bmatrix} \dot{r}_V \\ \dot{r}_\omega \end{bmatrix} = rJ_n \dot{q} 
\]

where:

\( \dot{q} \) is the vector of joint velocities,
\( \mathbf{r} \mathbf{V}_n \) and \( \mathbf{r} \mathbf{\omega}_n \) define the translational and angular velocities of frame \( n \) referred to frame \( r \),
\( \mathbf{r} \mathbf{J}_n \) is the Jacobian matrix of link \( n \), referred to frame \( r \).

The following models can be generated from the menu kinematic

### 4.1 Calculation of the Jacobian matrix

SYMORO+ calculates the Jacobian matrix using the method developed by Renaud [9]. It gives the Jacobian matrix as the product of three matrices, two of them are of full rank and the third contains simple terms such that:

\[
\begin{bmatrix}
  \mathbf{r} \mathbf{A}_i & 0_3 \\
  0_3 & \mathbf{r} \mathbf{A}_i 
\end{bmatrix}
\begin{bmatrix}
  \mathbf{I}_3 & \mathbf{i} \hat{\mathbf{l}}_{j,n} \\
  \mathbf{0}_3 & \mathbf{I}_3 
\end{bmatrix}
\begin{bmatrix}
  \mathbf{i} \mathbf{J}_{n,j} 
\end{bmatrix}
\]

(4)

with \( 0_3 \) and \( \mathbf{I}_3 \) denotes the zero and identity (3x3) matrix respectively, the symbol \( \hat{\cdot} \) means the 3x3 matrix of the vector product; such that \( \mathbf{a} \times \mathbf{b} = \mathbf{a} \hat{\mathbf{b}} \).

The vectoriel matrix \( \mathbf{J}_{n,j} \) is given as:

\[
\mathbf{J}_{n,j} =
\begin{bmatrix}
  \sigma_f \mathbf{a}_f + \sigma_i(\mathbf{a}_j \times \mathbf{L}_{i,j}) & \ldots & \sigma_n \mathbf{a}_n + \sigma_i(\mathbf{a}_n \times \mathbf{L}_{n,j}) \\
  \sigma_j \mathbf{a}_f & \ldots & \sigma_j \mathbf{a}_n 
\end{bmatrix}
\]

(5)

where

- \( f \) is the first joint on the path between the base and link \( n \), such that \( f=1 \) in the case of serial robots.
- \( \mathbf{a}_j \) is the unit vector along the axis \( \mathbf{z}_j \)
- \( \mathbf{L}_{i,j} \) is the position vector connecting the origin of frame \( i \) to that of frame \( j \)
- \( \sigma_j \) is equal to 1 if \( j \) is rotational, and equal to 0 if \( j \) is translational

### 4.2 Calculation of the velocities of the links

The translational and angular velocities of links can be calculated using relation (3), they can be calculated more efficiently, from the number of operations point of view, by the following recursive algorithm, for \( j=1,...,N_L \),

\[
\begin{align*}
\mathbf{j} \mathbf{\omega}_i &= \mathbf{j} \mathbf{A}_i \mathbf{i} \mathbf{\omega}_i \\
\mathbf{j} \mathbf{\omega}_j &= \mathbf{j} \mathbf{\omega}_i + \sigma_j \mathbf{q}_j \mathbf{j} \mathbf{a}_j \\
\mathbf{j} \mathbf{v}_j &= \mathbf{j} \mathbf{A}_i (\mathbf{i} \mathbf{v}_i + \mathbf{i} \mathbf{\omega}_i \times \mathbf{i} \mathbf{p}_j) + \sigma_j \mathbf{q}_j \mathbf{j} \mathbf{a}_j
\end{align*}
\]

(6a, 6b, 6c)
where $i = a(j)$ denotes the link antecedent to $j$, and $i\mathbf{a}_j$ is the unit vector $[0 \ 0 \ 1]^T$. The initial values $0\omega_0$ and $0\mathbf{V}_0$ are the velocities of the base.

### 4.3 Calculation of link accelerations

Differentiating equation (3), we get the translational and rotational acceleration of link $n$ as:

$$
\begin{bmatrix}
\dot{\mathbf{V}}_n \\
\dot{\omega}_n
\end{bmatrix} = \dot{\mathbf{J}}_n \dot{q} + \mathbf{J}_n \ddot{q}
$$

(7)

The calculation of link accelerations using (7) is time consuming, it is more efficient to calculate the link accelerations by the following recursive equations, which can be obtained by differentiating equations (6):

$$
\dot{\mathbf{\omega}}_j = \dot{\mathbf{A}}_i \dot{\mathbf{\omega}}_i + \sigma_j (\dot{q}_j \dot{\mathbf{a}}_j + \dot{\mathbf{\omega}}_i \times \dot{q}_j \dot{\mathbf{a}}_j)
$$

(8)

$$
\dot{\mathbf{U}}_j = \dot{\mathbf{\omega}}_j \times \mathbf{\omega}_j + \dot{\mathbf{\omega}}_j
$$

(9)

$$
\dot{\dot{\mathbf{V}}}_j = \dot{\mathbf{A}}_i [i\dot{\mathbf{V}} + i\dot{\mathbf{U}}_i \text{Im}P_j] + \sigma_j [\dot{q}_j \dot{\mathbf{a}}_j + 2\dot{\mathbf{\omega}}_i \times \dot{q}_j \dot{\mathbf{a}}_j]
$$

(10)

where: $i = a(j)$, $\dot{\mathbf{\omega}}_i$ and $\dot{\mathbf{\omega}}_j$ are calculated using equations (6).

### 4.4 Calculation of $\dot{\mathbf{J}} \dot{q}$ of the links

In some applications (task space control), we need to calculate the vector $\dot{\mathbf{J}} \dot{q}$. From equation (7) it can be seen that $\dot{\mathbf{J}} \dot{q}$ can be obtained by the use of the recursive equations (8,..10) and by assuming $\ddot{q}_j$ equal zero [10].

### 4.5 Kinematic constraint equations

This function gives the relation between the velocities of the passive joints as function of the velocities of the motorized joints. It can be calculated by equating the velocities on the terminal frame of each loop using the two sides of the loop. From figure 3, we get:

$$
\begin{bmatrix}
\mathbf{V}_k \\
\mathbf{\omega}_k
\end{bmatrix} = k\mathbf{J}_k \dot{q}_1 = k^{+B}\mathbf{J}_k+B \dot{q}_2
$$

(11)

where $\dot{q}_1$ and $\dot{q}_2$ denote the velocities of the joints from the root of the loop to the opened joint, along each side of the loop.
As function of the type of the loop, spatial or planar, and the type of the opened joint, redundant rows in equation (11) can be automatically eliminated [11].

Doing this procedure on all the loops we obtain the kinematic constraint equation as:

\[
\begin{bmatrix}
W_a & W_p & 0 \\
W_{ac} & W_{pc} & W_c
\end{bmatrix}
\begin{bmatrix}
\dot{q}_a \\
\dot{q}_p \\
\dot{q}_c
\end{bmatrix} = 0
\] (12)

where \( q_a, q_p, q_c \) represent the velocity of active (motorized), passive, and opened joints respectively.

From the first row of equation (12) we obtain:

\[
\dot{q}_p = -W_p^{-1}W_a \dot{q}_a = W \dot{q}_a
\] (13)

The acceleration constraint equation can also be given by differentiating equation (12) with respect to the time as:

\[
\begin{bmatrix}
W_a & W_p & 0 \\
W_{ac} & W_{pc} & W_c
\end{bmatrix}
\begin{bmatrix}
\ddot{q}_a \\
\ddot{q}_p \\
\ddot{q}_c
\end{bmatrix} + \begin{bmatrix}
\Psi \\
\Phi
\end{bmatrix} = 0
\] (14)

In fact \( \Psi \) and \( \Phi \) are calculated using a recursive method similar to that calculating \( J^T \dot{q} \) as given in section 4.4.

### 4.6 Inverse kinematic model

The inverse kinematic model gives \( \dot{q} \) as function of the link velocities \( V_n, \omega_n \). The solution implies to calculate the inverse of the Jacobian matrix, which is reduced to the inversion of \( \dot{J} \dot{q} \). The determinant is also provided to study the singular configurations of the robot.

### 5- THE DYNAMIC MODELING

The following models can be obtained in the menu dynamic.

### 5.1 Inverse dynamic model (I.D.M)
The inverse dynamic model gives the motor torques or forces as a function of the joint positions, velocities and accelerations. The calculation of this model represent the computed control law which decouples and linearizes the equation of motion of the robots. The model generated by our program has a reduced number of operations, such that it can be used for dynamic control applications, and this is thanks to the use the base inertial parameters (see section 6) and a customized Newton Euler algorithm which is linear in the inertial parameters [12].

The I.D.M using Newton Euler algorithm is given as follows:

The following notations will be used:
- \( F_j \): total forces on link \( j \),
- \( M_j \): total moments on link \( j \) around the origin \( o_j \),
- \( f_j \): force on link \( j \) due to motor \( j \) and its antecedent link \( i \),
- \( m_j \): moment on link \( j \) due to motor \( j \) and the antecedent link \( i \),
- \( f_{e,j} \): the force of link \( j \) on the environment,
- \( m_{e,j} \): the moments of link \( j \) on the environment,
- \( \Gamma \): motor torques or forces vector,
- \( g \): acceleration of gravity,

The algorithm consists of two recursive calculations:

a- The forward calculation, for \( j=1,\ldots,N_L \), is given as:

\[
\begin{align*}
J F_j &= M_j j \dot{V}_j + J U_j j MS_j \\
J M_j &= J J_j j \omega_j + J J_j j \omega_j x (J J_j j \omega_j) + J M_S x j \dot{V}_j 
\end{align*}
\] (15)

where \( J \omega_j, J \dot{\omega}_j, J V_j, J U_j \) are calculated using equations.(6,8,9,10).

To take into account the gravity forces the gravity acceleration will be subtracted from the translational acceleration of the base such that:

\[
0 \dot{V}_0 = 0 \dot{V}_b - g, \ 0 \dot{\omega}_0 = 0 \dot{\omega}_b, \ 0 \omega_0 = 0 \omega_b
\]

b- By studying the equilibrium of each link, the backward recursive calculation, for \( j=N_L,\ldots,1 \), gives:

\[
\begin{align*}
f_f & = J F_j + \sum k f_k + f_{e,j} \\
f_f & = A_j f_f \\
M_j &= M_j + \sum k m_k + \sum k p_k x f_k + m_{e,j}
\end{align*}
\] (17)

(18)

(19)

projecting \( f_f \) or \( M_j \) on the joint axis and taking into account the inertia and frictions of the actuators, we get the motor torque as:
\[ \Gamma_j = (\sigma_j \hat{f}_j + \sigma_j \hat{n}_j)^T j a_j + I a j \ddot{q}_j + F v_j \ddot{q}_j + F s_j \text{sign} (\dot{q}_j) \]  

(20)

The sum sign in equations (17) and (19) is on \( k \), which denote all the links successors of \( j \) such that \( a(k) = j \).

For serial robot, the maximum number of operations of this algorithm is equal to \( 92N_L - 127 \) multiplications and \( 81N_L - 117 \) additions, for \( N_L = 6 \) these relations give 425 multiplications and 369 additions. This number will be further reduced for real robots, where many of the geometric parameters of distances are zero and those of angles are equal to \( k\pi/2 \), with \( k \) integer, and in particularly if the links are supposed symmetric. Table 2 gives the number of operations for the 6 d.o.f PUMA robot (using base inertial parameters as defined in section 6.4).

5.2 Dynamic model of Closed loop robots

The joint positions of the equivalent tree structure of a closed loop robot can be written as:

\[ q_{tr} = \begin{bmatrix} q_a \\ q_p \end{bmatrix} \]  

(21)

where \( q_a \), \( q_p \) represent the positions of active and passive joints respectively.

The dynamic model of a closed-loop structured robot can be obtained as a function of the corresponding tree structure dynamic model using the following relation [13,14]:

\[ \Gamma_m = G^T \Gamma_{tr} = = \Gamma_a + W^T \Gamma_p \]  

(22)

where:

\( \Gamma_m \) is the \((m \times 1)\) vector of the torques of motorized joints,
\( G = \partial q_{tr} / \partial q_a \) is the Jacobian matrix of \( q_{tr} \) with respect to \( q_a \),
\( W \) is defined in equation (13).
\( \Gamma_{tr} \) is the \((N_L \times 1)\) vector of the joint torques (or forces) of the corresponding tree structure, which is supposed as:

\[ \Gamma_{tr} = \begin{bmatrix} \Gamma_a \\ \Gamma_p \end{bmatrix} \]

where \( \Gamma_a \) and \( \Gamma_p \) denote the vectors of the torques corresponding to active and passive joints respectively.

\( \Gamma_{tr} \) can be obtained using Newton-Euler algorithm as given in section 5.1, while \( G \) can be obtained from the resolution of kinematic constraint equations.

5.3 Direct dynamic model (D.D.M)
The direct dynamic model is used to simulate the robot dynamics, it permits to calculate the joint accelerations as a function of the input torques or forces. Since the general form of the inverse dynamic model can be written as:

\[ \Gamma = A \ddot{q} + B(q, \dot{q})\dot{q} + Q \]

where :
- \( A \) is the inertia matrix of the robot,
- \( B(q, \dot{q})\dot{q} \) gives the Coriolis and centrifugal forces,
- \( Q \) is the gravity forces.

The direct dynamic model can be obtained as follows:

\[ \ddot{q} = A^{-1} [ \Gamma - H ] \]

where:
\[ H = B(q, \dot{q})\dot{q} + Q \]

Thus the calculation of \( A \), and \( H \) represent the direct dynamic model.

5.3.1 Calculation of the vector \( H \)

The vector \( H \) can be calculated by the Newton-Euler method, given in section 5.1 by noting that, see equation (23), it is equal to \( \Gamma \) under the condition that \( \ddot{q} = 0 \). To calculate \( H \) efficiently a separate function is given to calculate it using a customized symbolic calculation.

Table 2 gives the number of operations for calculating \( H \) for the PUMA robot (using base inertial parameters).

5.3.2 Calculation of the inertia matrix \( A \)

The calculation of the matrix \( A \) is given by an algorithm similar to the algorithm of Newton-Euler [15]. By using the fact that the \( j \)th column of \( A \) is equal to \( \Gamma \) if:

\[ \dot{q} = 0, \quad g = 0, \quad \ddot{q} = e_j \]

with \( e_j \) is the unit (\( N_L \times 1 \)) vector, whose elements are equal to zero except the \( j \)th component which is equal to 1.

To increase the efficiency of this method, we make use of the symmetrical property of \( A \) and we use the generalized link inertial parameters. The generalized link is defined as the fictitious link composed of link \( j \) and all the succeeding links articulated on it [16]. The algorithm is thus composed of two steps, the calculation of the inertial parameters of the generalized links and a customized Newton-Euler algorithm which take into account the conditions of equation (26).

The inertial parameters of the generalized link \( j \) are denoted as:

\( M_j^+, J_j^+, MS_j^+ \), they will be calculated by the following algorithm:
Initialization: for $j = 1, \ldots, N_L$:

$$\begin{align*}
\mathbf{j}_j^+ &= \mathbf{j}_j, \\
\mathbf{M}_j^+ &= \mathbf{M}_j
\end{align*}$$

for $j = N_L, \ldots, 2$ and $a(j) \neq 0$:

$$\begin{align*}
a(j)\mathbf{M}_j &= a(j)\mathbf{A}_j \mathbf{M}_j
\end{align*}$$

(27)

$$\begin{align*}
a(j)\mathbf{j}_{a(j)}^+ &= a(j)\mathbf{j}_{a(j)} + a(j)\mathbf{A}_j \mathbf{j}_{a(j)} - [a(j)\mathbf{P}_j a(j)\mathbf{M}_j + (a(j)\mathbf{P}_j a(j)\mathbf{M}_j)^T] + a(j)\mathbf{P}_j a(j)\mathbf{P}_j^T \mathbf{M}_j
\end{align*}$$

(28)

$$\begin{align*}
a(j)\mathbf{M}_{a(j)}^+ &= a(j)\mathbf{M}_{a(j)} + a(j)\mathbf{A}_j \mathbf{M}_j + a(j)\mathbf{P}_j \mathbf{M}_j
\end{align*}$$

(29)

$$\begin{align*}
\mathbf{M}_{a(j)} &= \mathbf{M}_{a(j)} + \mathbf{M}_j
\end{align*}$$

(30)

Using the conditions (26) in Newton Euler algorithm, the recursive forward calculation will be reduced to:

$$\begin{align*}
\mathbf{j}_j^F &= \mathbf{\sigma}_j [0 \ 0 \ M_j^+]^T + \mathbf{\bar{\sigma}}_j [ -M\mathbf{Y}_j^+ \ M\mathbf{X}_j^+ \ 0]^T
\end{align*}$$

(31)

$$\begin{align*}
\mathbf{j}_j^M &= \mathbf{\sigma}_j [ XZ_j^+ \ YZ_j^+ \ ZZ_j^+ ]^T + \mathbf{\bar{\sigma}}_j [ \ M\mathbf{Y}_j^+ \ -M\mathbf{X}_j^+ \ 0 \ ]^T
\end{align*}$$

(32)

The recursive backward calculation of the I.D.M will be reduced to

$$\begin{align*}
\mathbf{j}_j^F &= \mathbf{j}_j^F
\end{align*}$$

(33)

$$\begin{align*}
\mathbf{j}_j^M &= \mathbf{\sigma}_j [ \ M\mathbf{Y}_j^+ \ -M\mathbf{X}_j^+ \ 0 \ ]^T + \mathbf{\bar{\sigma}}_j [ XZ_j^+ \ YZ_j^+ \ ZZ_j^+ ]^T
\end{align*}$$

(34)

$$\begin{align*}
\mathbf{A}_{j,j} &= \mathbf{\sigma}_j \ M_j^+ + \mathbf{\bar{\sigma}}_j \ ZZ_j^+ + \mathbf{I}_{a_j}
\end{align*}$$

(35)

where: $\mathbf{A}_{j,j}$ is the $(j,j)$ element of the matrix $\mathbf{A}$

To calculate the other elements of the column $j$ ($\mathbf{A}_{a(j),j}, \ldots, \mathbf{A}_{s_j(0),j}$), where $s_j(0)$ indicates the succeeding link of the base on the path between link 0 and link $j$, we continue the backward calculations which gives the following relations for $k=j, a(j), a(a(j)), \ldots, s_j(0)$:

$$\begin{align*}
a(k)\mathbf{f}_{a(k)} &= a(k)\mathbf{A}_k \mathbf{k}_k
\end{align*}$$

(36)

$$\begin{align*}
a(k)\mathbf{m}_{a(k)} &= a(k)\mathbf{A}_k \mathbf{k}_k + a(k)\mathbf{P}_k \times a(k)\mathbf{f}_{a(k)}
\end{align*}$$

(37)

$$\begin{align*}
\mathbf{A}_{a(k),j} &= a(k)\mathbf{f}_{a(k)} (\mathbf{\sigma}_j a(k)\mathbf{f}_{a(k)} + \mathbf{\bar{\sigma}}_j a(k)\mathbf{m}_{a(k)})
\end{align*}$$

(38)

$\mathbf{A}_{i,j} = 0$ if link $i$ is not on the path between link $j$ and link 0.

Table 2, gives the number of operations for calculating the inertia matrix for the PUMA robot (using base inertial parameters).

### 5.4 Direct dynamic model without calculating the inertia matrix
An algorithm derived from the work of [17,18] is programmed in customized form to get directly the joint accelerations as function of joint positions, velocities and torques without calculating nor inverting the inertia matrix. This algorithm can be used only for open loop robots. Table 2 gives the number of operations for calculating the \textit{D.D.M} for the PUMA robot (using base inertial parameters).

5.5 Dynamic model using Lagrange equation

This function calculates the elements of the matrices \( A, B, \) and \( Q \) of the dynamic model defined in equation (23). Two methods has been developed to get the elements of \( B \) : the first based on differentiating the inertia matrix of the robot obtained in section 5.3; the other method uses the algorithm developed in [19]. Table 2 gives the number of operations for calculating the coefficients of the matrices \( A \) and \( B \) for the PUMA robot (using base inertial parameters).

6- THE IDENTIFICATION MODEL

In order to use the dynamic model in simulation or control we need to know the values of the dynamic (inertial and friction) parameters. The most appropriate method to evaluate these parameters is the use of the identification techniques. Many identification models which are linear in the dynamic parameters are proposed: the dynamic model, the filtered dynamic model, and the energy model. All these models are generated in SYMORO+ as given in the following sections.

6.1 The dynamic identification model: The dynamic model can be used to identify the inertial parameters [20,21,22]. Since the dynamic model is linear in the dynamic parameters, as defined in section 2.2, it can be written as follows:

\[
\Gamma = D(q, q', \ddot{q}) K \tag{39}
\]

where

- \( K \) is the \((N_p \times 1)\) vector of dynamic parameters.
- \( D \) is \((N_L \times N_p)\) matrix.
- \( N_p \) is the number of inertial and friction parameters.

To identify \( K \) a sufficient number of equations can be obtained by calculating relation (39) at different times. The least squares solution is generally used in the solution SYMORO+ gives the symbolic expressions of the elements of the matrix \( D \) using customized symbolic calculation. The calculation of the column \( j \) of the matrix \( D \) is obtained from the Newton Euler algorithm of the inverse dynamic model, section 5.1, with the assumption that
the the jth inertial parameters, denoted as \( K_j \), is equal to one while all the other inertial parameters are equal to zero. It is to be noted that the calculation of \( \dot{\omega}_j, \dot{\dot{\omega}}_j, \dot{V}_j, \dot{U}_j \) for \( j = 1, \ldots, N_L \) is calculated only once for all the columns.

### 6.2 The filtered dynamic identification model

The filtered dynamic model is proposed in [23,24,25] in order to get a model which is not function of the joint accelerations. We have proposed and programmed a new method to get this model in SYMORO+ [26]. The main idea of the proposed algorithm is derived from the Lagrangian equation which is given as:

\[
\Gamma = \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}} \right) - \frac{\partial L}{\partial q} \tag{40}
\]

with:
- \( L \) the Lagrangian of the system, equal to \( E - U \),
- \( E \) the kinetic energy of the system,
- \( U \) the potential energy of the system.

Equation (40), can be written as:

\[
\Gamma = \frac{d}{dt} D_1 (q, \dot{q}) K + D_2 (q, \dot{q}) K \tag{41}
\]

where

\[
D_1 (q, \dot{q}) K = \frac{\partial E}{\partial \dot{q}} \tag{42}
\]

and

\[
D_2 (q, \dot{q}) K = -\frac{\partial E}{\partial q} + \frac{\partial U}{\partial q} \tag{43}
\]

Applying a numerical filter, denoted \( F \), of second order or higher, on the two sides of equation (41) gives:

\[
\Gamma_f = D_{1df} (q, \dot{q}) K + D_{2df} (q, \dot{q}) K \tag{44}
\]

where the subscript "\( f \)" means the application of the filter \( F \), and "\( df \)" means the application of a filter \( F' \) which associate to the filter \( F \) a derivative action. For instance in the case of using second order filter \( F \) and \( F' \) could be taken as:

\[
F(s) = \frac{a^2}{(s+a)^2} \tag{45}
\]

\[
F'(s) = \frac{a^2 s}{(s+a)^2} \tag{46}
\]

SYMORO+ gives the symbolic expressions of the elements of the matrices \( D_1 \) and \( D_2 \) using customized symbolic calculation using the algorithm presented in [26].
6.3 The energy identification model

Using the dynamic model in the identification need to estimate or measure the joint accelerations. To overcome this difficulty a model based on the energy theorem has been proposed [27].

To simplify the writing we assume that the friction is neglected. From the energy theorem we get:

\[
\int_{t_1}^{t_2} \dot{q}^T \Gamma \, dt = H(t_2) - H(t_1) = \Delta h(q, \dot{q}) \, K
\]

(47)

where:

- \( H(t_i) \) is the total energy (kinetic and potential) at time \( t_i \), it is linear in the inertial parameters and can be written as:

\[ H = h(q, \dot{q}) \, K \]

(48)

- \( h \) is a row matrix function of \( q \) and \( \dot{q} \).

Since the kinetic and potential energies of link \( j \) can be written as:

\[
E_j = \frac{1}{2} [j\omega_j^T j \dot{J}_j + j \omega_j^T j \dot{V}_j + jM_j j \dot{V}_j + 2 \dot{M}S_j T (j \dot{V}_j \times j \omega_j)] \quad (49)
\]

\[
U_j = -g^T (0P_j + 0A_j jM_j) \quad (50)
\]

where,

- \( 0g \) is the acceleration of gravity referred to frame zero.
- \( 0P_j \) is the position of the origin of frame \( j \) w.r.t. frame zero.
- \( 0A_j \) is the 3x3 transformation matrix giving the orientation of frame \( j \) w.r.t. frame 0, such that:

\[
0A_j = [0s_j \quad 0n_j \quad 0a_j] \quad (51)
\]

with \( s_j, n_j, a_j \) are the unit vectors along the x, y, and z axis respectively.

The coefficients of the inertial parameters in the vector \( h \) can be given as follows:

\[
h_{XX_j} = \frac{1}{2} \omega_1,j \omega_1,j
\]

\[
h_{XY_j} = \omega_1,j \omega_2,j
\]

\[
h_{XZ_j} = \omega_1,j \omega_3,j
\]

\[
h_{YY_j} = \frac{1}{2} \omega_2,j \omega_2,j
\]

\[
h_{YZ_j} = \omega_2,j \omega_3,j
\]

\[
h_{ZZ_j} = \frac{1}{2} \omega_3,j \omega_3,j
\]

\[
h_{MX_j} = \omega_3,j V_2,j - \omega_2,j V_3,j - 0g^T 0s_j
\]

(52)
\[ h_{MYj} = \omega_{1,j} V_{3,j} - \omega_{3,j} V_{1,j} - g^T 0_n^j \]
\[ h_{MZj} = \omega_{2,j} V_{1,j} - \omega_{1,j} V_{2,j} - g^T 0_a^j \]
\[ h_{Mj} = \frac{1}{2} jV_j^T jV_j - g^T 0_P^j \]

where, \( j\omega_j \) and \( jV_j \) are represented by the vectors:
\[ j\omega_j = [\omega_{1,j} \omega_{2,j} \omega_{3,j}]^T \]  \hspace{1cm} (53)
\[ jV_j = [V_{1,j} V_{2,j} V_{3,j}]^T \]  \hspace{1cm} (54)

To identify \( K \) a sufficient number of equations can be obtained by calculating relation (47) between different intervals of time. The least squares solution is generally used in this identification.

SYMORO+ calculates the elements of the matrix \( h \) using customized symbolic calculation.

6.4 The base inertial parameters

The base inertial parameters are defined as the minimum parameters which can be used to get the dynamic model. They represent the set of parameters which can be identified using the dynamic or energy model, thus its determination is essential for the identification of the inertial parameters of robots. They constitute also the parameters to be adapted during an adaptive dynamic control strategy. The use of the base parameters in all the dynamic models presented in section (5) leads to reduce their computation complexity [12].

These parameters can be obtained from the classical inertial parameters by eliminating those which have no effect on the dynamic model and by regrouping some others. In [28,...,33] we have presented symbolic and numerical methods to calculate these parameters for serial, tree structured, or closed loop robots. These algorithms have been programmed in SYMORO+.

The program generates a new file of inertial parameters which can be used directly in the Dynamic or Identification menus.

7. OPTIMIZATION OF THE MODELS

The models obtained under customized symbolic form can be optimized from the number of operations point of view using the optimizer menu. The optimized output file can be given in either of the following format: Fortran, Mathematica, C, Maple, Matlab, such that the generated model can be used directly by these systems.

8. CONCLUSION
This paper presents the software package of symbolic modelling of robots SYMORO+. This package generates all the models needed in the simulation, identification, control and design of robots. The algorithms used in deriving these models have been presented, they have been programmed using MATHEMATICA system. A friendly user interface is developed in C. The paper gives also an overview of the best algorithms which can be used in modelling the robots. Current extension is concerned with the modelling of flexible robots [34] structure and walking legged robots.

ACKNOWLEDGMENT
This work has been supported by the "CRITT Productique de Pays de Loire", I would like to thank also all the members of the the robotics team of the "Laboratoire d'Automatique de Nantes" who have participated in this project, either by developing new algorithms in the modelling of robots or by testing this package. Particular thanks to C.Chevallereau, F.Bennis, Ph. Seigle, P.Restrepo, and D.Murareci who have been involved in programming some modules of SYMORO+.
