Abstract: For any non negative real values $h$ and $k$, an $L(h, k)$-labeling of a graph $G = (V, E)$ is a function $L : V \rightarrow \mathbb{R}$ such that $|L(u) - L(v)| \geq h$ if $(u, v) \in E$ and $|L(u) - L(v)| \geq k$ if there exists $w \in V$ such that $(u, w) \in E$ and $(w, v) \in E$. The span of an $L(h, k)$-labeling is the difference between the largest and the smallest value of $L$. We denote by $\lambda_{h,k}(G)$ the smallest real $\lambda$ such that graph $G$ has an $L(h, k)$-labeling of span $\lambda$. The aim of the $L(h, k)$-labeling problem is to satisfy the distance constraints using the minimum span.

In this paper, we study the $L(h, k)$-labeling problem on regular grids of degree 3, 4, and 6 for those values of $h$ and $k$ whose $\lambda_{h,k}$ is either not known or not tight. We also initiate the study of the problem for grids of degree 8. For all considered grids, in some cases we provide exact results, while in the other ones we give very close upper and lower bounds.

Keywords: $L(h, k)$-labeling, triangular grids, hexagonal grids, squared grids, octagonal grids

Biographical notes: Tiziana Calamoneri is assistant professor at the Department of Computer Science, University of Rome “La Sapienza”. She got her Ph.D. in Computer Science 1997, at University of Rome “La Sapienza,” Italy. Her research interests include parallel and sequential graph algorithms, channel assignment in wireless networks, two- and three-dimensional graph drawing, layout of interconnection networks topologies and optimal routing schemes.

Saverio Caminiti is a PhD student at the Department of Computer Science, University of Rome "La Sapienza", Italy. He got his Master Degree in Computer Science in 2003, at University of Rome "La Sapienza". His research interests include compact representation of data structures both in sequential and parallel settings, graph algorithms, and graph coloring.

Guillaume Fertin is a Professor at LINA (Laboratoire d’Informatique de Nantes-Atlantique), University of Nantes, France. He completed his PhD degree from University of Bordeaux, France, in 1999. Since 1996, he has been researching in optimization, discrete mathematics and algorithmics, with two main applications fields: interconnection networks and bioinformatics.
1 INTRODUCTION

In this paper, we are interested in the frequency assignment problem, that arises in wireless communication systems. More precisely, we focus here on minimizing the number of frequencies used in the framework where radio transmitters that are geographically close may interfere if they are assigned close frequencies. This problem has originally been introduced in (17) and was later developed in (12). It is equivalent to a graph labeling problem, in which the nodes represent the transmitters, and any edge joins two transmitters that are sufficiently close to potentially interfere. The aim here is to label the nodes of the graph in such a way that:

- any two neighbors (transmitters that are very close) are assigned labels (frequencies) that differ by a parameter at least $h$;
- any two nodes at distance 2 (transmitters that are close) are assigned labels (frequencies) that differ by a parameter at least $k$;
- the gap between the smallest and the greatest value for the labels is minimized.

This problem is usually referred to as the $L(h, k)$-labeling problem. More formally, for any non-negative real values $h$ and $k$, an $L(h, k)$-labeling of a graph $G = (V, E)$ is a function $L : V \rightarrow \mathbb{R}$ such that $|L(u) - L(v)| \geq h$ if $(u, v) \in E$ and $|L(u) - L(v)| \geq k$ if there exists $w \in V$ such that $(u, w) \in E$ and $(w, v) \in E$. The span of an $L(h, k)$-labeling is the difference between the largest and the smallest value of $L$. Hence, it is not restrictive to assume 0 as the smallest value of $L$, something which will be assumed throughout this paper. We denote by $\lambda_{h,k}(G)$ the smallest real $\lambda$ such that graph $G$ has an $L(h, k)$-labeling of span $\lambda$; we call $L(h, k)$ number of $G$ this value. The aim of the $L(h, k)$-labeling problem is to satisfy the distance constraints using the minimum span.

Since its definition (11) as a specialization of the frequency assignment problem in wireless networks (12; 17), the $L(h, k)$-labeling problem has been intensively studied. Note that the $L(h, k)$-labeling problem is a generalization of some standard graph colorings, such as the usual (or proper) coloring when $h = 1$ and $k = 0$, or the 2-distance coloring (equivalent to the proper coloring of the square of the graph) when $h = k = 1$. We also note that the case $h = 2$ and $k = 1$ (or, more generally $h = 2k$), called radio-coloring or $\lambda$-coloring, is the most widely studied (see for instance (7; 9; 13; 14)).

The decision version of the $L(h, k)$-labeling problem is NP-complete even for small values of $h$ and $k$ (2). This motivates seeking optimal solutions on particular classes of graphs (see for instance (3; 4; 8; 11; 18; 19; 20; 15) and (6) for a complete survey). Concerning the more specific grid topologies, a large number of papers has been published on the subject. For instance, Makansi (16) provided an optimal $L(0, 1)$-labeling for the grid, that is regular grids of degree 4 (see Figure (b)). Battiti, Bertossi and Bonuccelli (1) found an optimal $L(1, 1)$-labeling for hexagonal, squared and triangular grids (that is, respectively, regular grids of degree 3, 4 and 6, see Figures (a), (b) and (c)). The $L(2, 1)$-labeling problem of regular grids of degree $\Delta$, denoted $G_{\Delta}$, has been studied independently by different authors (3; 7) proving that $\lambda_{2,1}(G_{\Delta}) = \Delta + 2$ by means of optimal coloring algorithms. More recently, Fertin and Raspaud (10) determined several bounds on $\lambda_{h,k}$ for $d$-dimensional squared grids.

In (5) some values of $\lambda_{h,k}$ for regular grids of degree 3, 4, and 6 are exactly computed, while in some intervals different upper and lower bounds are given; moreover, the case $h < k$ is not considered at all. Our goal in this paper is to improve some of those bounds, as well as to consider the case $h < k$. Moreover, we extend this study to a new class of graphs, namely grids of degree 8. Grids of degree 8 can be defined as the strong product of two infinite paths (15) (see also Figure for a graphical representation of the four types of grids we study in this paper). Grids of degree 8 can also be seen as a natural extension of grids of degree 6, who themselves are an extension of grids of degree 4 (see Figures (a), (b) and (c)).

Figure 1 Grids studied in this paper: (a) $G_3$, (b) $G_4$, (c) $G_6$ and (d) $G_8$

Before going further, we observe that when $h < k$ (a case that we will consider in this paper), there are actually two ways to define the $L(h, k)$-labeling problem:

- The first one is the distance-based model, which asks that two neighbors in the graph differ by at least $h$, while two nodes at distance 2 differ by at least $k$. This means that when two nodes are at the same time connected by a 1-path and a 2-path (hence when there is a cycle of length 3 in the graph), we consider the distance to be 1, and thus impose only the condition on $h$.

- The second one is the max-based model, which asks that two nodes connected at the same time by a 1-path and a 2-path differ by at least $\max\{h, k\}$; in that
sense, this model is more restrictive than the distance-based model. In particular, this model imposes that any cycle of length 3 to be always labeled with three labels at least \( \max\{h, k\} \) apart from each other.

Note that when \( h \geq k \), the two definitions coincide, since \( \max\{h, k\} = h \). The same occurs when the considered graph has no triangles, which is the case for \( G_3 \) and \( G_4 \).

In this paper, in the study of \( G_6 \) and \( G_8 \), when \( h < k \), we chose to consider the max-based problem. As mentioned above, we study in this paper the \( L(h, k) \)-labeling problem on regular grids of degree 3, 4, and 6 for those values of \( h \) and \( k \) whose \( \lambda_{h,k} \) is either not known or not tight, and we also study the \( L(h, k) \)-labeling problem in a new class of graphs, namely grids of degree 8. For all considered grids, in some cases we provide exact results, or we give close upper and lower bounds (see Figure 6.2 at the end of the paper for a summary of results).

The paper is organized as follows: in Section 2, we give a few technical lemmas that will help to obtain general lower and upper bounds for the considered types of graphs, while in Sections 3.2, 4.2 and 4.2, we improve bounds on the \( L(h, k) \) number of grids for degree 3, 4, 6 and 8, respectively.

Note finally that if no confusion arises, we will speak interchangeably, in the rest of this paper, of a node and its label.

2 PRELIMINARIES

In this section, we show four different lemmas, which will prove to be useful in the rest of the paper. Lemmas 1 and 1 are concerned with lower bounds for the \( L(h, k) \) number, while Lemmas 2 and 3 deal with upper bounds.

**Theorem 1.** \( \lambda_{h,k}(G_\Delta) \geq h + (\Delta - 1)k \) when \( h \leq k \), for \( \Delta = 3, 4 \).

**Proof.** Consider an optimal \( L(h, k) \)-labeling of \( G_\Delta \), \( h \leq k \), \( \Delta = 3, 4 \), and let \( x \) be a node labeled 0. The smallest label among those of its neighbors must be at least \( h \). Furthermore, the \( \Delta \) neighbors of \( x \) are all connected by a 2-length path and hence their labels must differ by at least \( k \) from each other. It follows that the greatest label must be at least \( h + (\Delta - 1)k \).

**Lemma 1.** \( \lambda_{h,k}(G_\Delta) \geq \Delta k \) when \( h \leq k \), for \( \Delta = 6, 8 \).

**Proof.** Observe that \( G_6 \) and \( G_8 \) are characterized by the property that each pair of adjacent nodes is also connected by a 2-length path. This implies that, given an optimal \( L(h, k) \)-labeling of \( G_\Delta \), \( h \leq k \), \( \Delta = 6, 8 \), starting from a node \( x \) labeled 0, the smallest label, among those of their neighbors must be at least \( k \). With reasonings analogous to those of the previous proof, the claim follows.

**Lemma 2.** For any graph \( G \) and any \( h \leq k \), \( \lambda_{h,k}(G) \leq k \cdot \lambda_{1,1}(G) \).

**Theorem 1.** \( \lambda_{h,k}(G_\Delta) \geq h + (\Delta - 1)k \) when \( h \leq k \), for \( \Delta = 3, 4 \).

**Proof.** Consider the labeling \( L' \) obtained from \( L \) by substituting every label \( i \) with label \( ik \) \( (i = 0, 1, \ldots, \lambda_{1,1}(G)) \). We claim that \( L' \) is an \( L(h, k) \)-labeling of \( G \) with span \( k \cdot \lambda_{1,1}(G) \), provided \( h \leq k \). Indeed, any two neighbors, which differ by at least 1 in \( L \), differ by at least \( k \) in \( L' \); moreover, any two nodes connected by a 2-length path, which differ by at least 1 in \( L \) differ by at least \( k \) in \( L' \).

**Lemma 3.** For any graph \( G \) and any \( h \geq \frac{k}{2} \), \( \lambda_{h,k}(G) \leq h \cdot \lambda_{1,2}(G) \).

**Proof.** Analogously to the proof of Lemma 2, consider an \( L(1, 2) \) labeling, say \( L \), of \( G \). Consider the labeling \( L' \) obtained from \( L \) by substituting every label \( i \) with label \( ih \) \( (i = 0, 1, \ldots, \lambda_{1,2}(G)) \). Since \( h \geq \frac{k}{2} \), \( L' \) is an \( L(h, k) \)-labeling of \( G \) with span \( h \cdot \lambda_{1,2}(G) \). Indeed, any two neighbors, which differ by at least 1 in \( L \), differ by at least \( h \) in \( L' \); moreover, any two nodes connected by a 2-length path, which differ by at least 2 in \( L \) differ by at least \( 2h \geq k \) in \( L' \).

3 REGULAR GRIDS OF DEGREE 3

3.1 Upper Bounds for \( G_3 \)

**Proposition 1.** \( \lambda_{h,k}(G_3) \leq h + 2k \) when \( h \leq \frac{k}{2} \).

**Proof.** Consider an optimal \( L(1, 2) \)-labeling of \( G_3 \) over the set of labels \( \{0, 1, \ldots, 5\} \), whose general pattern is depicted in Figure 3.1(a). The idea is to substitute \( h \) to 1, \( k \) to 2, \( h+k \) to 3, \( 2k \) to 4, and \( h+2k \) to 5. In that case, the labeling that is produced is a feasible \( L(h, k) \)-labeling. Indeed, each pair of consecutive labels differs by either \( h \) or \( k \), but since we supposed \( h \leq \frac{k}{2} \), we have \( k - h \geq h \) and thus any two consecutive labels differ by at least \( h \). Similarly, any other pair of distinct labels differs by at least \( k \). Moreover, the largest label used is \( h + 2k \), hence the result.

**Figure 2** General patterns for \( L(h, k) \)-labelings of \( G_3 \):
(a) \( L(1, 2) \)-labeling ; (b) \( L(1, 1) \)-labeling

**Proposition 2.** \( \lambda_{h,k}(G_3) \leq \min\{5h, 3k\} \) when \( \frac{k}{2} \leq h \leq k \).
Proof. By Lemma 3, since \( \frac{k}{2} \leq h \) and since there exists an \( L(1,2) \)-labeling of \( G_3 \) that is of span 5 (see for instance the general pattern shown in Figure 3.1(a)), we know there exists an \( L(h,k) \)-labeling of \( G_3 \) of span 5\( h \).

Analogously, since \( h \leq k \), we obtain an \( L(h,k) \)-labeling of span 3\( k \) by Lemma 2; indeed, there exists an \( L(1,1) \)-labeling of \( G_3 \) that is of span 3 (whose general pattern is shown in Figure 3.1(b), see also (1)). \( \square \)

3.2 Lower Bounds for \( G_3 \)

Proposition 3. \( \lambda_{h,k}(G_3) \geq h + 2k \) when \( h \leq k \).

Proof. This bound directly comes from Lemma 1. \( \square \)

Figure 3  Neighborhood of a node labeled 0 in \( G_3 \)

Proposition 4. \( \lambda_{h,k}(G_3) \geq 3k \) when \( \frac{2k}{3} \leq h \leq k \).

Proof. Consider an optimal \( L(h,k) \)-labeling of \( G_3 \). Suppose, by contradiction, that \( \lambda_{h,k}(G_3) < 3k \). Let us consider a node labeled 0, and let \( x, y, z \) be its 3 neighbors. Without loss of generality, suppose \( x < y < z \).

In view of the \( L(h,k) \)-constraints, we must have \( x \geq h, \ y \geq x + k \geq h + k \), and \( z \geq y + k \geq h + 2k \). Furthermore, from the hypothesis \( \lambda_{h,k}(G_3) < 3k \), we have that \( z < 3k \), hence \( y \leq z - k < 2k \), and \( x \leq y - k < k \). Let \( x_1 \) and \( x_2 \), \( y_1 \) and \( y_2 \), \( z_1 \) and \( z_2 \) be the not 0 neighbors of \( x, y, \) and \( z \), respectively (see Figure 3.2).

Let us first prove that if \( y_m = \min\{y_1, y_2\} \) and \( y_M = \max\{y_1, y_2\} \), then \( y_m < y < y_M \). Indeed, if \( y < y_m \), then \( y_m \geq y + h \geq 2h + k \), and consequently \( y_M \geq 2h + 2k \). However, \( 2h + 2k \geq 3k \) (because we supposed \( h \geq \frac{2k}{3} \)), a contradiction to the fact that \( \lambda < 3k \). On the other hand, if \( y < y_M \), then \( y < y_M + h \).

And since \( y_M \geq y_m + h \geq 2k \), we end up with \( y \geq h + 2k \). However, by hypothesis we know that \( y < 2k \), a contradiction since \( h > 0 \). Thus we conclude that in all the cases, we have \( y_m < y < y_M \).

Now, in order to prove the statement, we will show that under the hypothesis \( \lambda_{h,k}(G_3) < 3k \), both cases \( x_1 < x_2 \) and \( x_1 > x_2 \) lead to a contradiction.

Case 1: \( x_1 < x_2 \). In this case \( x_1 \geq k \), as \( x_1 \) is connected by a 2-length path to node 0 (via \( x \)) and \( x_2 \geq x_1 + k \geq 2k \). If \( x_1 < x \), then \( x \geq x_1 + h \geq k + h \), a contradiction since \( x < k \). Hence, \( x < x_2 < x_1 \). It follows that \( x_1 \geq x + h \geq 2h \) and \( x_2 \geq x_1 + k \geq 2k + h \). Let us now consider \( y_1 \) and \( y_2 \).

Case 1.1: \( y_1 < y_2 \). Hence we know that \( y_1 < y < y_2 \).

In such a case \( y_1 \geq k \) and \( y_1 \leq y - h < 2k - h \). Note that \( y_1 < x_2 \) as \( y_1 < 2k - h \) and \( x_2 \geq 2k \). Let us consider the common neighbor of \( x_2 \) and \( y_1, \alpha, \) and let us study the relative position of its label with respect to \( x_2 \) and \( y_1 \).

- \( \alpha < y_1 < x_2 \). Then \( \alpha \leq y - k < k \); if \( x < \alpha \) we have \( \alpha \geq x + k \geq h + k \), a contradiction; on the other hand, if \( \alpha < x \) then \( \alpha \leq x - k < 0 \), a contradiction too.
- \( y_1 < x_2 < \alpha \). Then \( x_2 \leq \alpha - h < 3k - h \); from previous hypotheses we also have \( x_2 \geq 2h + k \), and this leads to a contradiction as \( 3k - h \leq 2h + k \) when \( h \geq \frac{2k}{3} \).
- \( y_1 < \alpha < x_2 \). We have again two cases. If \( y_1 < \alpha < y \) then \( \alpha \leq y - k < k \) and \( y_1 \leq \alpha - h < h - k \) that is a contradiction as \( y_1 \geq k \). If \( y_1 < \alpha < y \) then \( \alpha \leq x_2 - h < 3k - h \), \( y \leq \alpha - k < 2k - h \), and \( y_1 \leq y - h < 2k - 2h \) that is a contradiction as \( y_1 \geq k \) and \( k \geq 2k - 2h \) when \( \frac{2k}{3} \leq h \).

Case 1.2: \( y_1 > y_2 \). Thus we have \( y_1 > y > y_2 \). This implies that \( y_1 \geq y + h \geq 2h + k \). Hence, \( y_1 \) lies in the interval \([2h + k; 3k]\). However, we also know that \( x_2 \) lies in the interval \([2h + k; 3k]\). Since this interval is of width \( w \leq 2k - 2h \), we conclude that \( w < k \) (because we supposed \( h \geq \frac{2k}{3} \) and hence \( h \geq \frac{k}{2} \)). This leads to a contradiction because \( y_1 \) and \( x_2 \) must be at least \( k \) away from each other.

Case 2: \( x_1 > x_2 \). With considerations analogous to those done for case \( x_1 < x_2 \), we can derive \( x < x_2 < x_1 \) and \( 2h + k < x_1 < 3k \) and \( 2h < x_2 < 2k \). Now, let us look at \( y_1 \) and \( y_2 \).

Case 2.1: \( y_1 < y_2 \). We thus have \( y_1 < y < y_2 \). However, this leads to a contradiction. Indeed, \( y_1 > k \) as it is connected by a 2-length path to node 0, then \( x_2 \geq y_1 + k > 2k \).

Case 2.2: \( y_1 > y_2 \). We then have \( y_2 < y < y_1 \). This implies that \( y_1 \geq y + h \geq 2h + k \) and hence \( y_1 > x_2 \) as \( x_2 < 2k \). Now consider \( \alpha \), the common neighbor of \( x_2 \) and \( y_1 \).

- \( x_2 < y_1 < \alpha \). Then \( \alpha \geq y_1 + h \geq 3h + k \geq 3k \), a contradiction since we supposed \( \lambda < 3k \).
- \( \alpha < x_2 < y_1 \). Then \( \alpha \leq x_2 - h < 2k - h \). If \( \alpha > y \) then \( \alpha \geq y + k \geq h + 2k \), a contradiction; if \( \alpha < y \) then \( \alpha \leq y - k < k \). However, we know that \( x < k \); moreover, because \( \alpha < k \) and \( \alpha \) must lie at least \( k \) away from \( x \), this leads to a contradiction.
- \( x_2 < \alpha < y_1 \). Then \( \alpha \leq y_1 - h < 3k - h \). If \( \alpha > y \) then \( \alpha \geq y + k \geq h + 2k \) that is greater than \( 3k - h \) under the hypothesis \( h \geq \frac{2k}{3} \), a contradiction; if \( \alpha < y \) then \( \alpha \leq y - k < k \) that again contradicts the fact that \( \alpha \) must lie at least \( k \) away from \( x \).

Altogether, we see that every possible case leads to a contradiction. This proves that the initial assumption, \( \lambda < 3k \), is false, and consequently the proposition is proved. \( \square \)
Proposition 5. $\lambda_{h,k}(G_3) \geq 3h$ when $k \leq h \leq \frac{3k}{2}$.

Proof. The proof is analogous to the previous one, i.e., by contradiction we assume that there exists a $L(h,k)$-labeling with span $\lambda < 3h$, we start from node labeled 0, we look at its neighbors and prove that neither $x_1 < x_2$ nor $x_1 > x_2$ can occur. Wlog, let us assume $x < y < z$. Hence, $x \geq h$, $y \geq h + k$ and $z \geq h + 2k$. On the other hand, $z < 3h$, $y < 3h - k$ and $x < 3h - 2k$. Let $x_1$ and $x_2$, $y_1$ and $y_2$, $z_1$ and $z_2$ be the not 0 neighbors of $x$, $y$, and $z$, respectively (see Figure 3.2).

We first prove that if $y_m = \min\{y_1, y_2\}$ and $y_M = \max\{y_1, y_2\}$, then $y_m < y < y_M$. Indeed, if $y < y_m$, then $y_m \geq y + h \geq 2h + k$, and consequently $y_M \geq 2h + 2k$. However, $2h + 2k \geq 3h$ (because we supposed $h \leq \frac{3k}{2}$), a contradiction to the fact that $\lambda < 3h$.

On the other hand, if $y_M < y$, then $y \geq y_M + h$. And since $y_M \geq y_m + k \geq 2k$, we end up with $y \geq h + 2k$. However, by hypothesis we know that $y < 3h - k$, a contradiction since $3h - k \leq h + 2k$, because we supposed $h \leq \frac{3k}{2}$. Thus we conclude that in all the cases, we have $y_m < y < y_M$.

Now, as in the previous proof, let us consider $x_1$ and $x_2$ (see Figure 3.2), and show that, under the hypothesis $\lambda < 3h$, none of the cases $x_1 < x_2$ and $x_1 > x_2$ can occur.

Case 1: $x_1 < x_2$. This implies $x_1 \geq k$, as $x_1$ is connected by a 2-length path to node 0 (via $x$). If $x_1 < x$, then $x \geq x_1 + h \geq h + k$, that is a contradiction as $x < 3h - 2k \leq h + k$ under the hypothesis $h \leq \frac{3k}{2}$. Hence $x < x_1 < x_2$. It follows that $x_1 \geq x + h \geq 2h$ and $x_2 \geq x_1 + k \geq 2h + k$. Let us consider now $y_1$ and $y_2$.

Case 1.1: $y_1 < y_2$. Then we know that $y_1 < y < y_2$. Note that $y_1 < x_2$ as $x_2 \geq 2h + k$ and $y_1 \leq y - h \leq y_2 - 2h < 3h - 2h = h$. Now, let us consider $\alpha$, the common neighbor of $y_1$ and $y_2$.

- $y_1 < x_2 < \alpha$. The contradiction comes from the inequality $\alpha \geq x_2 + h \geq 3h + k$.

- $\alpha < y_1 < x_2$. Then $\alpha \geq y + h \geq h$, $y \geq y_1 + h \geq 2h$ and $y_2 \geq y + h \geq 3h$, a contradiction.

- $y_1 < \alpha < x_2$. Since we have $y_1 \geq k$, this implies $\alpha \geq y_1 + h \geq h + k$ and $\alpha \leq x_2 - h < 2h$. It is easy to see that the same bounds hold also for $y$. Hence $y$ and $\alpha$ both lie in the interval $[h + k; 2h]$, of width $w < h - k$, that is $w \leq k$. The contradiction comes from the fact that $\alpha$ and $y$ being connected by a 2-length path, they must lie at least $k$ away from each other.

Case 1.2: $y_1 > y_2$. Thus, we know that $y_1 > y > y_2$. We know that $x_2$ and $y_1$ must be at least $k$ away from each other. Moreover, $2h + k \leq x_2 < 3h$ and $2h + k \leq y_1 < 3h$. Hence, both $x_2$ and $y_1$ lie in an interval of width $w < h - k$. Since we supposed $h \leq \frac{3k}{2}$, we conclude $w < k$, a contradiction.

Case 2: $x_1 > x_2$. We can easily see that in that case we must have $x_1 > x_2 > x$. Indeed, $x_2 \geq k$, since it is connected by a 2-length path to node 0. Hence, if $x > x_2$, then $x \geq h + k$. However, we know that $x < 3h - 2k$, a contradiction since $h \leq \frac{3k}{2}$. Hence we conclude that $x_1 > x_2 > x$, which implies $x_2 \geq x + h \geq 2h$ and $x_1 \geq x_2 + k \geq 2h + k$. Now let us consider $y_1$ and $y_2$.

Case 2.1: $y_1 < y_2$. Let us then consider $\alpha$, the common neighbor of $y_1$ and $y_2$, and let us look at its relative position compared to $x$ and $y$. There are three possible cases.

- $\alpha > y > x$. We recall that we are in the case $x_1 > x_2 > x$, that is $x_2 \geq x + h \geq 2h$. If $\alpha > x_2$ then $\alpha \geq x_2 + h \geq 3h$, a contradiction to the hypothesis $\lambda < 3h$. Now, if $\alpha < x_2$, $\alpha \leq x_2 - h$. Since $x_2 \leq x_1 - k < 3h - k$, we conclude $\alpha \leq 2h - k$. But $y \geq h + k$ and $y \geq y + k$, that is $\alpha \geq h + 2k$. This is a contradiction since $2h - k \leq h + 2k$, by the hypothesis that $h \leq \frac{3k}{2}$.

- $y > x > \alpha$. In that case, if $\alpha < y_1$, then $y_1 \geq \alpha + h \geq h$, which implies $y \geq 2h$ and $y_2 \geq 3h$, a contradiction to the hypothesis $\lambda < 3h$. Now, if $\alpha > y_1$, then $\alpha \geq h$, which in turns means that $x \geq h + k$ and $y \geq h + 2k$. However, we know that $y < 3h - k$, a contradiction since $3h - k \leq h + 2k$ due to the fact that we supposed $h \leq \frac{3k}{2}$.

Case 2.2: $y_1 > y_2$. Here, we consider the three nodes $z, z_1$ and $z_2$. We first show that if $z_M = \min\{z_1, z_2\}$ and $z_M = \max\{z_1, z_2\}$, then $z_M < z_M < 3h$. Indeed, if $z_M > z$ then $z_M \geq z + h$, and since we know $z \geq h + 2k$, we conclude $z_M \geq 2h + 2k$, a contradiction to the fact that $\lambda < 3h$ since $2h + 2k \geq 3h$. Now let us look at the relative positions of $z_1$ and $z_2$. There are two cases to consider.

- $z_1 > z_2$. In that case, we have $z > z_1 > z_2$. Now let us look at $\beta$, common neighbor of $z_1$ and $y_2$, and let us consider the relative positions of $\beta$ and $y$.

  - $\beta < y$. First, we note that $\beta < z_1$. Indeed, $z_2 \geq k$ (it is connected by a 2-length path to node 0), thus $z_1 \geq 2k$. However, $\beta < y$ by hypothesis, hence $\beta \leq y - k$, that is $\beta < 2h - k$. Moreover, $2h - k \leq 2h$ since we are in the case $\lambda \leq \frac{3k}{2}$, and thus we conclude that $\beta < z_1$. This implies $\beta \leq z_1 - h$, that is $\beta \leq 2h - \beta$; and since $z \leq 2h < 3h$, we get $\beta < h$. On the other hand, $y_2 < y$, thus $y_2 \leq y - h$. But since $y < 2h$, we then have $y_2 < h$. Hence, both $\beta$ and $y_2$ lie in the interval $[0; h]$. However, they are neighbors and thus should have labels that are at least $h$ away, a contradiction.

  - $\beta > y$. Then we have $\beta \geq y + k$, that is $\beta \geq h + 2k$. However, we know that $z \geq h + 2k$ as
well. Thus, \( \beta \) and \( z \) lie in the interval \([h + 2k; \lambda]\), where \( \lambda < 3h \) by hypothesis. Thus the width of this interval \( w \) satisfies \( w < 2h - 2k \), and thus \( w < k \) because we supposed \( h < \frac{3k}{2} \). However, \( \beta \) and \( z \) are neighbors, and thus should have labels at least differing by \( h \), a contradiction with the fact that \( w < h \).

- \( z_2 > z_1 \). In that case, we know that \( z > z_2 > z_1 \). In particular, this means that \( z_2 < 2h \), and \( z_1 < 2h - k \). However, \( z_1 \geq k \) since it is connected by a 2-length path to node 0. We also have \( y \leq z - h < 2h \), and thus \( y \leq y - h < h \); and since \( h \geq k \), we conclude that \( y \leq 2h - k \). Moreover, \( y_2 \geq k \) since it is connected by a 2-length path to node 0. Hence, both \( z_1 \) and \( y_2 \) lie in the interval \([0; 2h - k]\), of width \( w < 2h - 2k \), that is \( w < k \) since we supposed \( h < \frac{3k}{2} \). However, \( z_1 \) and \( y_2 \) are connected by a 2-length path, and thus should have labels at least differing from \( k \), a contradiction.

Altogether, we see that every possible case leads to a contradiction. This proves that the initial assumption, \( \lambda < 3h \), is false, and consequently the proposition is proved.

**Proposition 6.** \( \lambda_{h,k}(G_3) \geq h + 3k \) when \( \frac{3k}{2} \leq h \leq 2k \).

**Proof.** Consider an optimal \( L(h, k) \)-labeling of \( G_3 \) with span \( \lambda \). By contradiction, suppose \( \lambda < h + 3k \). Let us consider a node labeled 0, and let \( x, y, z \) be its 3 neighbors. Without loss of generality, suppose \( x < y < z \).

In view of the \( L(h, k) \)-constraints, we must have \( x \geq h \), \( y \geq x + k \geq h + k \), and \( z \geq y + k \geq h + 2k \). Furthermore, for the hypothesis \( \lambda < h + 3k \), \( z < h + 3k \), hence \( y \leq z - k < h + 2k \), and \( z \leq y - k < h + k \). Let \( x_1 \) and \( x_2 \), \( y_1 \) and \( y_2 \), and \( z_1 \) and \( z_2 \) be the not 0 neighbors of \( x, y, z \), respectively (see Figure 3.2).

Let us first prove the following, which will be useful in the rest of the proof: if \( y \leq \min(y_1, y_2) \) and \( y M = \max(y_1, y_2) \), then \( y < y < y M \). Indeed, if \( y < y < y M \), we have \( y \geq y + h \geq 2h + k \), and \( y \geq y + h = 2h + k \). This contradicts the fact that \( \lambda < h + 3k \), because \( 2h + 2k \geq h + 3k \) (since we supposed \( h \geq \frac{3k}{2} \)). Now suppose \( y < y < y M \). Then \( y < y < y M \), because it is connected by a 2-length path to node 0. Thus \( y < y M < h + 2k \), and \( y < y M < h + 2k \), which contradicts the fact that \( y < h + 2k \). Altogether, we conclude that the only possible case is \( y \leq \min(y_1, y_2) \).

In the following we show that, under the hypothesis \( \lambda < h + 3k \), both cases \( x_1 < x_2 \) and \( x_1 > x_2 \) lead to a contradiction, which will prove the statement.

**Case 1:** \( x_1 < x_2 \). This implies \( x_1 \geq k \), as \( x_1 \) is connected by a 2-length path to node 0 (via \( x \)) and \( x_2 \geq x_1 + k \geq 2k \). If \( x_1 < x \), then \( x \geq x_1 + h \geq k + h \), that is a contradiction as \( x < h + k \). Hence, we have \( x < x_1 < x_2 \). It follows that \( x_1 \geq x + h \geq 2h \) and \( x_2 \geq x_1 + k \geq 2h + k \). Moreover, \( x_1 \leq x_2 - k < h + 2k \) and \( x \leq x_1 - h < 2k \). Let us now consider \( y_1 \) and \( y_2 \).

**Case 1.1:** \( y_1 < y_2 \). By (1) above, we have \( y_1 < y < y_2 \). Let us now consider \( \alpha \) (common neighbor of \( y_1 \) and \( x_2 \)), and let us study its relative position compared to \( x \) and \( y \) (we recall that \( x < y \) by hypothesis).

- \( \alpha > y > x \). Hence we have \( \alpha \geq y + k \geq h + 2k \). But \( x_2 \geq 2h + k \geq h + 2k \) as well. Hence, both \( \alpha \) and \( x_2 \) lie in the interval \([h + 2k; h + 3k]\) of width \( w < k \). However, \( x_2 \) and \( \alpha \) are neighbors, thus they must be at least \( h \) away, a contradiction.

- \( y > \alpha > x \). In that case, \( \alpha \leq y - k < 2k \). But we also have \( \alpha \geq x + k \geq h + k \), a contradiction.

- \( y > x > \alpha \). Since \( x < 2k \), we conclude that \( \alpha \leq x - k < k \). However, we know \( y_1 \geq k \) (because it is connected by a 2-length path to node 0). Thus \( \alpha \geq y_1 \), hence \( y_1 \geq \alpha + h \geq h \). But we know \( y_1 < y < y_2 \), thus \( y_1 \leq y - h \), and \( y < y_2 - h < 3k \), thus \( y < y_2 - k \). But we cannot have \( y_1 \geq h \) and \( y_2 < 3k - h \), since \( h < \frac{3k}{2} \).

**Case 1.2:** \( y_2 < y_1 \). By (1) above, we have \( y_2 < y < y_1 \). Hence \( y \geq y + h \geq 2h + k \). We also know that \( x_2 \geq 2h + k \), since \( x < x_2 \). Thus \( y_1 \) and \( x_2 \) share the same interval \([2h + k; h + 3k]\), of width \( w < 2k - h < k \). But \( y_1 \) and \( x_2 \) are connected by a 2-length path, and thus must be at least \( k \) away, which is impossible.

Hence, at this point we conclude that necessarily \( x_1 > x_2 \). Thus let us consider this case.

**Case 2:** \( x_2 < x_1 \). In that case, it is easily seen that actually \( x_1 > x_2 > x \), since \( x > x_2 \) would imply \( x_{\geq x + h} \); and since \( x_2 \geq k \) (it is connected by a 2-length path to node 0), we would have \( x \geq h + k \), a contradiction to the fact that \( x < h + k \). Now let us look again at the relative positions of \( y_1 \) and \( y_2 \).

**Case 2.1:** \( y_1 < y_2 \). By (1) above, we have \( y_1 < y < y_2 \). This implies that \( y \leq y_2 - h < 3k \). And since we know by hypothesis that \( x < y \), we conclude that \( x < y < y_2 \).

- \( \alpha > y > x \). Then \( \alpha \geq y + k \geq h + 2k \). However, we know \( y \leq y_1 \), that is \( y < y_1 < x \). Thus \( \alpha \geq x + h \), and since \( x_2 > x \) we have \( x_2 \geq x + h \geq 2h \). We conclude \( \alpha \geq 3h \), a contradiction to the fact that \( \lambda < h + 3k \), since we supposed \( h < \frac{3k}{2} \).

- \( y > \alpha > x \). Then \( \alpha \leq x + k \geq h + k \), and \( \alpha \leq y - k < 2k \). This is a contradiction since \( h + k \geq 2k \) by hypothesis.

- \( y > x > \alpha \). Then \( \alpha \leq x - k < k \). However, \( y_1 \geq k \) (it is connected by a 2-length path to node 0). Thus \( y_1 \geq \alpha \), which means \( y_1 \geq \alpha + h \geq h \). But we know that \( y_1 < y \), that is \( y \leq y_1 < y_2 \). This is a contradiction since \( h \geq 3k - h \) by hypothesis.

**Case 2.2:** \( y_1 > y_2 \). By (1) above, we have \( y_2 < y < y_1 \). Let us now look at the relative positions of \( z, z_1 \) and \( z_2 \). We
first note that if \( z_m = \min \{z_1, z_2\} \) and \( z_M = \max \{z_1, z_2\} \), then \( z_m < z_M < z \). Indeed, if \( z_M > z \) then \( z_M \geq z + h \), and since we know \( z \geq h + 2k \), we conclude \( z_M \geq h + 3k \), a contradiction.

- \( z_1 > z_2 \). Hence \( z > z_1 > z_2 \), by the argument above. Let us derive here some inequalities that will be useful in the following. Since \( z < h + 3k \) and \( z_1 \leq z - h \), we conclude \( z_1 < 3k \). Moreover, we know that \( z_2 \geq k \) and \( z_1 > z_2 \), thus we conclude \( z_1 \geq z_2 + k \geq 2k \). Finally, we recall that \( h + 2k \leq z < h + 3k \). Now let us look at the relative positions of \( \beta \) and \( y \).

- \( \beta < y \). Then \( \beta \leq y - k < 2k \). Since \( z_1 \geq 2k \), we conclude \( \beta < z_1 \). Thus \( \beta < z_1 - h \leq 3k - h \).

We also know that \( y_2 \leq 3k - h \) because \( y_2 < y \leq y - h \), and because \( y < 3k \). Hence, both \( \beta \) and \( y_2 \) are contained in the interval \([0; 3k - h]\), of width \( w < 3k - h \). But \( 3k - h \leq h \) by hypothesis, and since \( \beta \) and \( y_2 \) must be at least \( h \) away, this is impossible.

- \( \beta > y \). Then \( \beta \geq y + k \geq h + 2k \). This implies that both \( \beta \) and \( z \) lie in the interval \([h + 2k; h + 3k]\), of width \( w < k \). However, \( \beta \) and \( z \) must be at least \( k \) away from each other, a contradiction.

- \( z_2 > z_1 \). Hence \( z > z_2 > z_1 \). In particular, we have \( k \leq z_1 < 2k \). But we also know that \( k \leq y_2 < 3k - h \leq 2k \). Thus \( y_2 \) and \( z_1 \) both lie in the interval \([k; 2k]\), of width \( w < k \). But they must be at least \( k \) away, a contradiction.

Altogether, we have shown that every possible case leads to a contradiction. This proves that the initial assumption, \( \lambda < h + 3k \), is false. This proves the proposition.

### 4 REGULAR GRIDS OF DEGREE 4

#### 4.1 Upper Bounds for \( G_4 \)

**Proposition 7.** \( \lambda_{h,k}(G_4) \leq h + 3k \) when \( h \leq \frac{k}{2} \).

**Proof.** Consider the \( L(1,2) \)-labeling whose general pattern is depicted in Figure 4.1(a). This labeling has span 7. If we now substitute labels 0, 1, 2, 3, 4, 5, 6, 7, the new labeling we obtain is an \( L(h,k) \)-labeling of \( G_4 \). Indeed, it is easy to see that when \( h \leq \frac{k}{2} \), each pair of consecutive labels differs by at least \( h \), while each other pair of distinct labels differs by at least \( k \). Moreover, the largest label used is \( h + 3k \), hence the result.

**Proposition 8.** \( \lambda_{h,k}(G_4) \leq \min \{7h, 4k\} \) when \( \frac{k}{2} \leq h \leq k \).

**Figure 4** General patterns for \( L(h,k) \)-labelings of \( G_4 \):
(a) \( L(1,2) \); (b) \( L(1,1) \) ; (c) \( L(3,2) \)

**Proof.** By Lemma 3, since \( \frac{k}{2} \leq h \) and since there exists an \( L(1,2) \)-labeling of \( G_4 \) that is of span 7 (as shown in Figure 4.1(a)), we know there exists an \( L(h,k) \)-labeling of \( G_4 \) of span 7k.

Analogously, since \( h \leq k \), we obtain an \( L(h,k) \)-labeling of span 4k by Lemma 2 ; indeed, there exists an \( L(1,1) \)-labeling of \( G_4 \) that is of span 4 (whose pattern is shown in Figure 4.1(b), see also (1)).

**Proposition 9.** \( \lambda_{h,k}(G_4) \leq 3h + k \) when \( \frac{3k}{2} \leq h \leq \frac{5k}{3} \).

**Proof.** Consider the \( L(3,2) \)-labeling of \( G_4 \) whose general pattern is depicted in Figure 4.1(c). This labeling has span 11. If we now substitute labels 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, the new labeling we obtain is an \( L(h,k) \)-labeling of \( G_4 \). By construction, any pair of labels that are at least 3 away in the list differs by at least \( h \), while any pair of labels that is at least 2 away in the list differs by at least \( k \), because we supposed \( \frac{3k}{2} \leq h \). Moreover, the largest label used is \( 3h + k \), hence the result.

**Proposition 10.** \( \lambda_{h,k}(G_4) \leq \frac{11k}{2} \) when \( \frac{11k}{8} \leq h \leq \frac{3k}{2} \).

**Proof.** It is known (see (5)) that \( \lambda_{h,k}(G_4) \leq 4h \) when \( h \geq k \). Since \( \lambda_{h,k} \) is a non decreasing function, Proposition 9 implies that \( \lambda_{h,k}(G_4) \leq \frac{11k}{2} \) when \( \frac{11k}{8} \leq h \leq \frac{3k}{2} \).

#### 4.2 Lower Bounds for \( G_4 \)

**Proposition 11.** \( \lambda_{h,k}(G_4) \geq h + 3k \) when \( h \leq k \).

**Proof.** This bound directly comes from Lemma 1.

### 5 REGULAR GRIDS OF DEGREE 6

**Proposition 12.** \( \lambda_{h,k}(G_6) = 6k \) when \( h \leq k \).

**Proof.** The upper bound is proved observing that since \( h \leq k \), we obtain an \( L(h,k) \)-labeling of span 6k by Lemma 2 ; indeed, there exists an \( L(1,1) \)-labeling of \( G_6 \) of span 6, whose general pattern is shown in Figure 4.2 (see also (1)). The lower bound directly comes from Lemma 1.

### 6 REGULAR GRIDS OF DEGREE 8
6.1 Upper Bounds for \( G_8 \)

Proposition 13. \( \lambda_{h,k}(G_8) \leq 8k \) when \( h \leq k \).

Proof. Since \( h \leq k \), we obtain an \( L(h,k) \)-labeling of span 8\( k \) by Lemma 2; indeed, there exists an \( L(1,1) \)-labeling of \( G_8 \) of span 8 (whose general pattern is shown in Figure 6.1(a)).

Proposition 14. \( \lambda_{h,k}(G_8) \leq \min \{8h,10k\} \) when \( k \leq h \leq 2k \).

Proof. Once again we exploit the \( L(1,1) \)-labeling of \( G_8 \) whose general pattern is depicted in Figure 6.1(a). If we substitute \( 0, h, 2h, \ldots, 8h \) to labels \( 0, 1, \ldots, 8 \), the new labeling we obtain is an \( L(h,k) \)-labeling of \( G_8 \). Indeed, it is easy to see that each pair of consecutive labels differs by at least \( h \), and thus by at least \( k \) since \( k \leq h \). Moreover, the largest label used is \( 8h \), hence the result.

The upper bound of 10\( k \) comes from the \( L(2,1) \)-labeling of \( G_8 \) whose general pattern is shown in Figure 6.1(b). If we substitute \( 0, k, 2k, \ldots, 10k \) to labels \( 0, 1, \ldots, 10 \), the new labeling we obtain is an \( L(h,k) \)-labeling of \( G_8 \). Indeed, it is easy to see that when \( k \leq h \leq 2k \), each pair of nonconsecutive labels differs by at least \( 2k \geq h \), while any pair of distinct labels differs by at least \( k \). Moreover, the largest label used is \( 10k \), hence the result.

Proposition 15. \( \lambda_{h,k}(G_8) \leq \min \{5h,14k\} \) when \( 2k \leq h \leq 3k \).

Proof. Consider the \( L(2,1) \)-labeling whose general pattern is described in Figure 6.1(b). This labeling has span 10. If we now substitute \( 0, k, h+k, 2h, 2h+k, 3h, 3h+k, 4h, 4h+k, 5h \) to labels \( 0, 1, \ldots, 10 \), the new labeling we obtain is an \( L(h,k) \)-labeling of \( G_8 \). Indeed, it is easy to see that each pair of nonconsecutive labels differs by at least \( h \). On the other hand, since \( 2k \leq h \), any pair of distinct labels differs by at least \( k \). Moreover, the largest label used is \( 5h \).

Analogously, the other bound is given using an \( L(3,1) \)-labeling, such as the one whose general pattern is shown in Figure 6.1(c). This labeling is of span 14. If we now substitute \( 0, k, 2k, \ldots, 14k \) to labels \( 0, 1, \ldots, 14 \), the new labeling we obtain is an \( L(h,k) \)-labeling of \( G_8 \). Indeed, when \( h \leq 3k \), each pair of labels that are at least 3 away in the list differs by at least \( 3k \geq h \), while any pair of distinct labels differs by at least \( k \). Moreover, the largest label used is \( 14k \), hence the result.

Proposition 16. \( \lambda_{h,k}(G_8) \leq 4h+2k \) when \( 3k \leq h \leq 6k \).

Proof. Starting from the \( L(3,1) \)-labeling used in the previous proof (cf. also Figure 6.1(c)) of span 14, we substitute labels \( 0, k, 2k, h, h+k, h+2k, 2h, 2h+k, \ldots, 4h, 4h+k, 4h+2k \) to labels \( 0, 1, \ldots, 14 \). This new labeling is also an \( L(h,k) \)-labeling of \( G_8 \). Indeed, each pair of labels that are at least 3 away in the list differs by at least \( h \) by construction, while any pair of distinct labels differs by at least \( k \) because \( h \geq 3k \). Moreover, the largest label used is \( 4h+2k \), hence the result.

Proposition 17. \( \lambda_{h,k}(G_8) \leq 3h+8k \) when \( h \geq 6k \).

Proof. Consider the labeling whose general pattern is depicted in Figure 6.1(a). This labeling is an \( L(1,1) \)-labeling of span 11, with the additional property that the only consecutive labels that can appear on neighboring nodes are of the form \( 3i+2 \) and \( 3(i+1) \). We now replace any label \( l \) of this labeling by a new label, thanks to the following rule (cf. Figure 6.1(b)): any label of the form \( l = 3i+j \) (\( i = 0, 1, 2, 3, j = 0, 1, 2 \)) is replaced by \( l' = (b+2k)i+j \). In this new labeling, any pair of labels of the form \( 3i+2 \) and \( 3(i+1) \) is now separated by \( h \). Moreover, the labeling we started from is an \( L(1,1) \)-labeling, and any two differing labels in the new labeling are at least \( k \) away. Thus, this new labeling is an \( L(h,k) \)-labeling of span \( 3h+8k \).
Problem on regular grids of degree 3, 4, 6 and 8, and we have improved, in many different cases, the bounds on the greatest label. Let us consider a label \( x \) which is neither 0 nor \( \lambda \) (note that there must exist one since \( G_8 \) contains \( K_3 \) as an induced subgraph; note also that necessarily, \( x \) lies in the interval \([h; \lambda - h]\)). Now, consider its 8 neighbors, say \( v_1 \ldots v_8 \). Then no other label than \( x \) can be used in the interval \([x-h; x+h]\) for the \( v_i \)'s. However, all the \( v_i \)s are pairwise connected by 2-length paths, so they must be at least \( k \) away from each other. If there are \( \alpha \) (resp. \( \beta \)) labels for the \( v_i \)s in the interval \([0; x-h]\) (resp. \([x+h; \lambda]\)), then we must have \((x-h) - (\alpha - 1)k \geq 0\) and \( \lambda \geq (x+h) + (\beta - 1)k \), with \( \alpha + \beta = 8 \). Since \( \lambda_{h,k}(G_8) = \lambda \), we conclude that \( \lambda_{h,k}(G_8) \geq 2h + (\alpha + \beta - 2)k \), hence the result.

**Proposition 20.** \( \lambda_{h,k}(G_8) \geq 3h + 3k \) when \( h \geq 3k \).

**Proof.** First, observe that we have \( \lambda_{h,k}(G_8) \geq 3h + k \). Indeed, consider an optimal \( L(h, k) \)-labeling of \( G_8 \), a node labeled 0, and the set of its neighbors (see Figure 6.2). Wlog., suppose \( \min\{a, b, c\} \leq \min\{e, f, g\} \). Since \( a, b \) and \( c \) are neighbors of 0, then we have \( \min\{a, b, c\} \geq h \). And since any node among \( e, f \) and \( g \) is connected by a 2-length path to any node among \( a, b \) and \( c \), we conclude that \( \min\{e, f, g\} \geq h + k \). Finally, since \( e, f \) and \( g \) induce a \( K_3 \), we have \( \max\{e, f, g\} \geq 3h + k \).

**Figure 8** Neighborhood of a node labeled 0 in \( G_8 \).

However, we can derive a better lower bound of \( 3h + 3k \), taking into account nodes \( d \) and \( h \) in addition to the previous study. This bound then derives from a very tedious case by case analysis that is not developed here. Instead, we have run an exhaustive search by computer on the grid restricted to those nine nodes. The source and binary codes corresponding to this search are available at the following URL: http://www.sciences.univ-nantes.fr/info/perso/perma-

### 7 CONCLUDING REMARKS

In this paper, we have studied the \( L(h, k) \)-labeling problem on regular grids of degree 3, 4, 6 and 8, and we have improved, in many different cases, the bounds on the \( L(h, k) \) number in each of these classes of graphs. A graphical representation of our results is depicted in Figure 6.2: bold lines in this figure are results from this paper, grey lines are previously known results, and grey zones represent the gaps that still exist between the known lower and upper bounds.

Though we managed to obtain tight bounds in several cases, there are still some other cases for which the gap is not closed, and it actually looks difficult to improve the bounds without using case by case analysis arguments, as we have sometimes done in this paper. However, a natural question consists in closing the gaps that still remain in all the four classes of graphs considered here.

Moreover, as observed in the introduction, when \( h < k \) we have considered in this paper the \textit{max-based} model, that imposes a condition on labels of nodes connected by a 2-length path instead of using the concept of \textit{distance} 2 (we recall that when \( h \geq k \), the two definitions coincide). Hence, it is also natural to ask for a similar study in the case \( h < k \), but using this time the \textit{distance-based} definition. We note that this makes sense only for \( G_8 \) and \( G_9 \), since there are no triangles in \( G_3 \) and \( G_4 \), and thus in that case the two definitions coincide. Moreover, since the \textit{max-based} model is by definition more restrictive than the \textit{distance-based} model, the upper bounds we obtain in the \textit{max-based} model also apply in the \textit{distance-based} model, while this is not a priori the case for lower bounds.

### REFERENCES

Summary of the results achieved in this paper: bold lines are results from this paper, grey lines are previously known results, and grey zones represent the gaps that still exist between the known lower and upper bounds.
