Abstract

This paper deals with the problem of estimating the tail of a bivariate distribution function. To this end we develop a general extension of the POT (Peaks-Over-Threshold) method, mainly based on a two-dimensional version of the Pickands-Balkema-de Haan Theorem. We introduce a new parameter that describes the nature of the tail dependence, and we provide a way to estimate it. We construct a two-dimensional tail estimator and study its asymptotic properties. We also present real data examples which illustrate our theoretical results.

Keywords: Extreme Value Theory, Peaks Over Threshold method, Pickands-Balkema-de Haan Theorem, Tail dependence.

2000 MSC: 62H12, 62H05, 60G70.

1. Introduction

The univariate POT (Peaks-Over-Threshold) method is common for estimating extreme quantiles or tail distributions (see e.g. McNeil 1997, 1999 and references therein). A key idea of this method is that a distribution is in the domain of attraction of an extreme value distribution if and only if the distribution of excesses over high thresholds is asymptotically generalized Pareto (GPD) (e.g. Balkema and de Haan, 1974; Pickands, 1975):

\[
V_{\xi,\sigma}(x) := \begin{cases} 
1 - (1 - \frac{\xi x}{\sigma})^{\frac{1}{\xi}}, & \text{if } \xi \neq 0, \sigma > 0, \\
1 - e^{-\frac{x}{\sigma}}, & \text{if } \xi = 0, \sigma > 0,
\end{cases}
\]

and \(x \geq 0\) for \(\xi \leq 0\) or \(0 \leq x < \frac{\sigma}{\xi}\) for \(\xi > 0\). This univariate modeling is well understood, and has been discussed by Davison (1984), Davison and Smith (1990) and other papers of these authors.

In this paper, we are interested in the problem of fitting the joint distribution of bivariate observations exceeding high thresholds. To this end we develop
a bivariate estimation procedure, mainly based on a version of the Pickands-
Balkema-de Haan Theorem in dimension 2 (Theorem 2.1). This extension al-
low us to consider a two-dimensional structure of dependence between both con-
tinuous random components \( X \) and \( Y \). This dependence is modeled via a
copula \( C \), which is supposed to be unknown.

We recall here some classical bivariate threshold models, based on a characteri-
sation of the joint tail by Resnick (1987). Letting

\[
\begin{aligned}
\text{equation of } (Y_1, Y_2) \text{ with marginals } F_j, j = 1, 2. \text{ Define } Z_j = -1/\log(F_j(Y_j)), j = 1, 2, \text{ i.e. each } Y_j \text{ is transformed to a unit Fréchet variable and } P(Z_j \leq z) = \exp^{-1/z}, \\

\text{for } 0 < z < \infty. \text{ Let } F_* \text{ denote the joint distribution of } (Z_1, Z_2), \text{ we have } F(y_1, y_2) = F_*(z_1, z_2). \text{ The assumption that } F \text{ is in the maximum domain of attraction (MDA) of a bivariate extreme value distribution } G \text{ is equivalent assuming } F_* \text{ to be in the domain of attraction of a bivariate extreme value distribution } G_*, \text{ where the marginals of } G_* \text{ are unit Fréchet. The characterization of Resnick (1987) can be written as}
\end{aligned}
\]

\[
\begin{align}
\lim_{t \to \infty} \frac{\log(F_*(tz_1, tz_2))}{\log(F_*(t, t))} &= \lim_{t \to \infty} \frac{1 - F_*(tz_1, tz_2)}{1 - F_*(t, t)} = \frac{\log(G_*(z_1, z_2))}{\log(G_*(1, 1))}.
\end{align}
\]

Equating the left and the right-hand terms for large \( t \) leads to the following
model for the joint tail of \( F \) (see Ledford and Tawn, 1996):

\[
\begin{align}
\mathcal{F}_1(y_1, y_2) &= \exp \{-l(-\log(F_{Y_1}(y_1)), -\log(F_{Y_2}(y_2)))\},
\end{align}
\]

for \( y_j > u_j \), where \( u_j \) are high thresholds for the marginal distributions and \( l \)
is the stable tail dependence function of the limiting extreme value distribution
\( G_* \). Then approximation (3) can be estimated by

\[
\begin{align}
\mathcal{F}_1^*(y_1, y_2) &= \exp \{-\hat{l}(-\log(\hat{F}_{Y_1}^*(y_1)), -\log(\hat{F}_{Y_2}^*(y_2)))\},
\end{align}
\]

for high values of \( y_1 \) and \( y_2 \), where \( \hat{F}_{Y_1}^*(y_1) \) (resp. \( \hat{F}_{Y_2}^*(y_2) \)) is an estimator for the
marginal tail of \( Y_1 \) (resp. \( Y_2 \)). For instance \( \hat{F}_{Y_1}^*(y_1) \) (resp. \( \hat{F}_{Y_2}^*(y_2) \)) comes from
the univariate POT method described in Section 4.1. In (4) \( \hat{l} \) is an estimator
of the stable tail dependence function (see Drees and Huang, 1998; Draisma et al., 2004; Einmahl et al., 2008). For another approach, based on the estimation
of the so-called univariate dependence function of Pickands (Pickands, 1981),
see for instance Capéraà and Fougeres (2000). Problems arise with both these
bivariate techniques when \( (Y_1, Y_2) \) are asymptotically independent i.e.,

\[
\lambda := \lim_{t \to 0} P[F_{Y_1}^{-1}(Y_1) > 1 - t | F_{Y_2}^{-1}(Y_2) > 1 - t] = 0.
\]

When the data exhibit positive or negative association that only gradually dis-
sappears at more and more extreme levels, these methods produce a significant
introduced a model in which the tail dependence is characterized by a coeffi-
cient \( \eta \in (0, 1] \). In these works the joint survival distribution function of a
bivariate random vector \((Z_1, Z_2)\) with unit Fréchet marginals is assumed to satisfy 
\[ P[Z_1 > z, Z_2 > z] \sim L(z) P[Z_1 > z]^\frac{1}{\eta}, \]
where \(L\) is a slowly varying function at infinity. Various methods to estimate this coefficient \(\eta\) are proposed in Peng (1999), Draisma et al. (2004), Beirlant et al. (2011). For some counter-examples of the Ledford and Tawn’s model see Schlather (2001).

Contrarily to this approach, we propose a model based on regularity conditions of the copula and on the explicit description of the dependence structure in the joint tail (see condition in (8) in Proposition 2.1). The study of tail dependence from a distributional point of view by means of appropriate copulae has received attention in the past decade. The interested reader is referred to Juri and Wüthrich (2002, 2004), Wüthrich (2004), Charpentier and Juri (2006), Charpentier and Segers (2006), Javid (2009).

The general idea of our model is to decompose the estimation of \(P(X \leq x, Y \leq y)\), for \(x, y\) above some marginal thresholds \(u_X, u_Y\), in the estimation of different bivariate regions. For the joint upper tail in \([u_X, x] \times [u_Y, y]\) we use the non parametric estimators coming from Theorem 2.1 (see Section 2). For the lateral regions \([-\infty, x] \times [-\infty, u_Y]\) and \([-\infty, u_X] \times [-\infty, y]\) we approximate the distribution function \(F\) using (3). The stability of our estimation compared to the one of \(\hat{F}_1\) is analyzed on some real cases (Section 7) which have been studied in other papers (e.g. Beirlant et al., 2011; Frees and Valdez 1998; Lescourret and Robert, 2006). Therefore our estimator, in a different way from the Ledford and Tawn’s method, covers situations less restrictive than dependence or perfect independence above thresholds. Note also that our method is free from the pre-treatment of data because we can work directly with the original general samples without the transformation in Fréchet marginal distributions.

Finally, we recall that, in the past decade, bivariate extensions of the POT method via generalized Pareto distribution have been developed in a series of papers by Falk and Reiss (2005 and references therein) or in Reiss and Thomas (2007; Chapter 13). Recently a multivariate generalization is treated in Beirlant et al. (2004), Rootzén and Tajvidi (2006) and Michel (2008). The role of multivariate generalized Pareto distributions in the framework of extreme value theory is still under scrutiny. In contrast to the univariate case it is not intuitively clear, how exceedances over high thresholds are to be defined. Our paper makes a contribution to this part of recent literature. To the best of our knowledge the POT procedure we propose in this paper can not be directly deduced from POT methods proposed in works cited above. Moreover we provide an estimation of bivariate tails such this type of estimation is not obtained in the papers cited above. However, some ingredients for a comparison are investigated in Theorem 4.2 in Juri and Wüthrich (2004).

The paper is organized as follows. In Section 2 we state an extension of the Pickands- Balkema-de Haan Theorem in the case of bivariate distributions with different marginals (Theorem 2.1). In Section 3 we provide a new non parametric estimator for the dependence structure of a bivariate random sample in the upper tail. In Section 4.2 we recall the POT procedure for univariate distributions and we use Theorem 2.1 in order to build a new estimator for the tail of the
bivariate distribution. The study of the asymptotic properties of our estimator makes use of a convergence result in univariate case (Theorem 5.1) dealing with asymptotic behavior of the absolute error between the theoretical distribution function and its tail estimator. In Section 6 we present the consistency result of our estimator with its convergence rate both in the asymptotic dependent case (Theorem 6.1) and in the asymptotic independent one (Theorem 6.2). Examples with real data are presented in Section 7. Some auxiliary results and more technical proofs are postponed to the Appendix.

Remark 1 Assume we observe \( X_1, \ldots, X_n \) i.i.d. with common distribution function \( F \). If we fix some high threshold \( u \), let \( N \) denote the number of excesses above \( u \). In the following, two approaches will be considered. In the first one, we work conditionally on \( N \). If \( n \) is the sample size and \( u_n \) the associated threshold, the number of excesses is \( m_n \), with \( \lim_{n \to \infty} m_n = \infty \) and \( \lim_{n \to \infty} m_n/n = 0 \). The second approach considers the number of excesses \( N_n \) as a binomial random variable (which is the case in the simulations), \( N_n \sim \text{Bi} (n, 1 - F(u_n)) \) with \( \lim_{n \to \infty} 1 - F(u_n) = 0 \) and \( \lim_{n \to \infty} n(1 - F(u_n)) = \infty \). Keeping in mind these considerations will be useful in the following (in particular in Section 5).

2. On the two-dimensional Pickands-Balkema-de Haan Theorem

A central one dimensional result in univariate tail estimation is the so-called Pickand-Balkema-de Haan Theorem. As our aim is the estimation of bivariate tails, we are interested in two-dimensional extensions of this theorem. Such a two dimensional generalization can be found in the literature (e.g. see Juri and Wüthrich, 2004; Wüthrich, 2004) with the assumption \( F_X = F_Y \). Starting from Theorem 4.1 in Juri and Wüthrich (2004) and Theorem 3.1 in Charpentier and Juri (2006), we provide here a precise formulation and proof of a general bivariate Pickands-Balkema-de Haan Theorem (Theorem 2.1 below). We first introduce some notation and recall results from Juri and Wüthrich (2004) and Nelsen (1999), which we will need later.

We consider a 2-dimensional copula \( C(u, v) \) and the associated survival copula \( C^*(u, v) \). In a first time we assume that \( X \) and \( Y \) are uniformly distributed on \([0, 1]\). Let us fix a threshold \( u \in [0, 1) \) such that \( \mathbb{P}[X > u, Y > u] > 0 \), i.e. such that \( C^*(1 - u, 1 - u) > 0 \). We consider the distribution of \( X \) and \( Y \) conditioned on \( \{X > u, Y > u\} \):

\[
\forall x \in [0, 1], \quad F_{X,u}(x) := \mathbb{P}[X \leq x \mid X > u, Y > u] = 1 - \frac{C^*(1 - x \lor u, 1 - u)}{C^*(1 - u, 1 - u)},
\]

(6)

\[
\forall y \in [0, 1], \quad F_{Y,u}(y) := \mathbb{P}[Y \leq y \mid X > u, Y > u] = 1 - \frac{C^*(1 - u, 1 - y \lor u)}{C^*(1 - u, 1 - u)}.
\]

(7)

Note that the continuity of the copula \( C \) implies that \( F_{X,u} \) and \( F_{Y,u} \) are also continuous.
Definition 2.1 Let $X$ and $Y$ be uniformly distributed on $[0,1]$. Assume that for a threshold $u \in [0,1]$, $C^*(1-u,1-u) > 0$. We define the upper-tail dependence copula at level $u \in [0,1)$ relative to the copula $C$ by

$$C_u^p(x,y) := \mathbb{P}[X \leq \bar{F}_{X,u}(x), Y \leq \bar{F}_{Y,u}(y) \mid X > u, Y > u],$$

$\forall (x,y) \in [0,1]^2$, where $\bar{F}_{X,u}, \bar{F}_{Y,u}$ are given by (6)-(7).

Note that $\mathbb{P}[X \leq x, Y \leq y \mid X > u, Y > u] \bigg|_{x,y=1}$ obviously defines a two-dimensional distribution function whose marginals are given by $\bar{F}_{X,u}$ and $\bar{F}_{Y,u}$. We remark that $C_u^p(x,y)$ is a copula and from the continuity of $\bar{F}_{X,u}$ and $\bar{F}_{Y,u}$ we obtain the uniqueness of $C_u^p$. Moreover, the asymptotic behavior of $C_u^p$ for $u$ around 1 describes the dependence structure of $X,Y$ in their upper tails.

In order to provide an explicit form for $\lim_{u \to 1} C_u^p(x,y)$, we state Proposition 2.1 below, which is a modification of Theorem 3.1 in Charpentier and Juri (2006). More precisely we adapt Theorem 3.1 in Charpentier and Juri (2006) in the case of Upper-tail dependence copula, assuming that $C$ satisfies suitable regularity condition under the direction $(1-u,1-u)$ (see the limit in (8)). For comparisons we refer to Section 3 in Charpentier and Juri (2006).

Proposition 2.1 Assume that $\partial C^*(1-u,1-v)/\partial u < 0$ and $\partial C^*(1-u,1-v)/\partial v < 0$ for all $u,v \in [0,1)$. Furthermore, assume that there is a positive function $G$ such that

$$\lim_{u \to 1} \frac{C^*(x(1-u), y(1-u))}{C^*(1-u,1-u)} = G(x,y), \text{ for all } x, y > 0. \quad (8)$$

Then for all $(x,y) \in [0,1]^2$

$$\lim_{u \to 1} C_u^p(x,y) = x + y - 1 + G(g_X^{-1}(1-x), g_Y^{-1}(1-y)) := C^*G(x,y), \quad (9)$$

where $g_X(x) := G(x,1)$, $g_Y(y) := G(1,y)$. Moreover there is a constant $\theta > 0$ such that, for $x > 0$

$$G(x,y) = \begin{cases} x^\theta g_Y \left( \frac{y}{x} \right) & \text{for } \frac{y}{x} \in [0,1], \\ y^\theta g_X \left( \frac{x}{y} \right) & \text{for } \frac{x}{y} \in (1, \infty). \end{cases} \quad (10)$$

The proof of Proposition 2.1 is postponed to the Appendix. We adapt in our setting the proof of Theorem 3.1 by Charpentier and Juri (2006). Since $\partial C^*(1-u,1-v)/\partial u < 0$ and $\partial C^*(1-u,1-v)/\partial v < 0$ for all $u,v \in [0,1)$, we have $C^*(1-u,1-u) > 0$, for all $u \geq 0$, i.e. $C_u^p$ is well defined for all $u \geq 0$. Then we ask that the joint survival distribution function of $X$ and $Y$, uniformly distributed on $[0,1]$, is strictly decreasing in each coordinate. As in Remark 3.2 in Charpentier and Juri (2006) one can prove that the convergence in (9) is uniform in $[0,1]^2$. From Proposition 2.1, functions $G, g_X$, and $g_Y$ characterize the asymptotic behavior of the dependence structure for extremal events.
Remark 2
. We note that $C^* G(x, y)$ defined in (9) is the survival copula of the copula $C^G(x, y) := G(g_X^{-1}(x), g_Y^{-1}(y))$ and thus, in particular, is a copula (for more details see Section 3 in Charpentier and Juri, 2006).
. In the case of symmetric copula, i.e. $C(u, v) = C(v, u)$ for all $u$ and $v$, the limit $G$ in (8) is continuous, symmetric, with marginals $G(x, 1) = G(1, x) = g(x)$, where $g : [0, \infty) \to [0, \infty)$ is a strictly increasing function and $g(x) = x^\theta g(1/x)$ for all $x \in (0, \infty)$ (for more details about properties of $G$ in the symmetric case see Section 2 in Juri and Wüthrich, 2004).

In the univariate setting de Haan (1970) proves that $F \in MDA(H_\xi)$ is equivalent to the existence of a positive measurable function $a(\cdot)$ such that, for $1 - \xi x > 0$ and $\xi \in \mathbb{R}$,

$$\lim_{u \to x_F} \frac{1 - F(u + x a(u))}{1 - F(u)} = \begin{cases} (1 - \xi x)^\frac{\theta}{1 - \theta}, & \text{if } \xi \neq 0, \\ e^{-x}, & \text{if } \xi = 0, \end{cases} \quad (11)$$

where $x_F := \sup\{x \in \mathbb{R} | F(x) < 1\}$. It allows stating below a rigorous formulation of the two-dimensional Pickands-Balkema-de Haan Theorem in a general case.

**Theorem 2.1** Let $X$ and $Y$ be two continuous real valued random variables, with different marginal distributions, respectively $F_X$, $F_Y$, and copula $C$. Suppose that $F_X \in MDA(H_\xi)$, $F_Y \in MDA(H_\xi)$ and that $C$ satisfies assumptions of Proposition 2.1. Then

$$\sup_{\mathcal{A}} \left| \Pr[X - u \leq x, Y - F_Y^{-1}(F_X(u)) \leq y | X > u, Y > F_Y^{-1}(F_X(u))] - C^* G \left(1 - g_X(1 - V_{\xi_1, a_1}(u)(x)), 1 - g_Y(1 - V_{\xi_2, a_2}(F_Y^{-1}(F_X(u)))(y))\right) \right|_{u \to x_F} \to 0, \quad (12)$$

where $V_{\xi_i, a_i(\cdot)}$ is the GPD with parameters $\xi_i, a_i(\cdot)$ defined in (1), $a_i(\cdot)$ is as in (11), for $i = 1, 2$, $\mathcal{A} := \{(x, y) : 0 < x \leq x_F - u, 0 < y \leq x_F - F_Y^{-1}(F_X(u))\}$, with $x_F := \sup\{x \in \mathbb{R} | F_X(x) < 1\}$, $x_F := \sup\{y \in \mathbb{R} | F_Y(y) < 1\}$.

The proof of Theorem 2.1 is postponed to the Appendix.

3. Estimating dependence structure in the bivariate framework

It is well known that a bivariate distribution function $F$ with continuous marginal distribution functions $F_X$, $F_Y$ is said to have a stable tail dependence function $l$ if for $x \geq 0$ and $y \geq 0$ the following limit exists:

$$\lim_{t \to 0} \frac{1}{t} \Pr[1 - F_X(X) \leq tx \text{ or } 1 - F_Y(Y) \leq ty] := l(x, y) \quad (13)$$
or similarly
\[
\lim_{t \to 0} \frac{1}{t} \mathbb{P}[1 - F_X(X) \leq tx, 1 - F_Y(Y) \leq ty] := R(x, y) = x + y - l(x, y), \tag{14}
\]

see e.g. Huang (1992). If \( F_X, F_Y \) are in the maximum domain of attraction of two extreme value distributions \( H_X, H_Y \) and if (13) holds then \( F \) is in the domain of attraction of an extreme value distribution \( H \) with marginals \( H_X, H_Y \) and with copula determined by \( l \). Furthermore (13) is equivalent to

\[
\lim_{t \to 0} \frac{1}{t} (1 - C(1 - tx, 1 - ty)) = l(x, y), \quad \text{for } x \geq 0, y \geq 0. \tag{15}
\]

Note that the upper tail dependence coefficient defined in (5) is such that \( \lambda = R(1, 1) \). We introduce the non parametric estimators for \( l \) and \( R \) (see Einmahl et al., 2006):

\[
\hat{l}(x, y) = \frac{1}{k_n} \sum_{i=1}^{n} 1\{R(X_i) > n-k_n x+1 \text{ or } R(Y_i) > n-k_n y+1\}, \tag{16}
\]

\[
\hat{R}(x, y) = \frac{1}{k_n} \sum_{i=1}^{n} 1\{R(X_i) > n-k_n x+1, R(Y_i) > n-k_n y+1\}, \tag{17}
\]

where \( k_n \to \infty, k_n/n \to 0 \) and \( R(X_i) \) is the rank of \( X_i \) among \( (X_1, \ldots, X_n) \), \( R(Y_i) \) is the rank of \( Y_i \) among \( (Y_1, \ldots, Y_n) \), for \( i = 1, \ldots, n \).

### 3.1. Asymptotic dependent case

If \( X \) and \( Y \) are asymptotically dependent \( (\lambda > 0) \) we introduce an estimator for \( G, g_X \) and \( g_Y \) which will be used later to estimate the tail of the bivariate distribution function. Using (13)-(15), we write

\[
g_X(x) = \frac{x + 1 - l(x, 1)}{2 - l(1, 1)} = \frac{R(x, 1)}{R(1, 1)}, \quad g_Y(y) = \frac{y + 1 - l(1, y)}{2 - l(1, 1)} = \frac{R(1, y)}{R(1, 1)},
\]

\[
G(x, y) = \frac{x + y - l(x, y)}{2 - l(1, 1)} = \frac{R(x, y)}{R(1, 1)}.
\]

Using (10), as \( R \) is homogeneous of order one then \( \theta = 1 \). As \( \eta \in (0, 1] \) in the Ledford and Tawn’s model (see Ledford and Tawn 1996, 1997, 1998), \( \theta \) describes the nature of the tail dependence, it does not depend on the marginal distribution functions.

In order to estimate \( g_X, g_Y \) and \( G \), we use the non parametric estimator for \( R \) in (17) and we obtain

\[
\hat{g}_X(x) = \frac{\hat{R}(x, 1)}{\hat{R}(1, 1)}, \quad \hat{g}_Y(y) = \frac{\hat{R}(1, y)}{\hat{R}(1, 1)}, \quad \text{and} \quad \hat{G}(x, y) = \frac{\hat{R}(x, y)}{\hat{R}(1, 1)}. \tag{18}
\]
Using (18) we get a non parametric estimator for \( \theta \), for \( x > 0 \)
\[
\hat{\theta}_x = \begin{cases} 
\frac{\log(G(x,y)) - \log(g(x))}{\log(x)} & \text{if } \frac{y}{x} \in [0,1], \\
\frac{\log(G(x,y)) - \log(g(y))}{\log(y)} & \text{if } \frac{y}{x} \in (1,\infty).
\end{cases} 
\]  
(19)

Following Remark 2, in the case of a symmetric copula, using \( g_X(x) = g_Y(x) = g(x) = x^\theta g(1/x) \) for \( x > 0 \), we get
\[
\hat{\theta}_x = \frac{\log(g(x)) - \log(g(1/x))}{\log(x)}.
\]  
(20)

Using Theorem 2.2 in Einmahl et al. (2006) (see Theorem C in Appendix) we state the following consistency result for \( \hat{G}, \hat{g}_X \) and \( \hat{g}_Y \):

**Corollary 3.1** Under assumptions of Theorem C if we have \( v_n \) such that \( v_n/\sqrt{k_n} \to 0, \) for \( n \to \infty, \) and \( \lambda > 0 \) we obtain
\[
v_n \sup_{0 < x, y \leq 1} |\hat{G}(x,y) - G(x,y)| \xrightarrow{p} 0, \\
v_n \sup_{0 < x \leq 1} |\hat{g}_X(x) - g_X(x)| \xrightarrow{p} 0, \\
v_n \sup_{0 < y \leq 1} |\hat{g}_Y(y) - g_Y(y)| \xrightarrow{p} 0.
\]
with \( \hat{g}_X(x), \hat{g}_Y(y) \) and \( \hat{G}(x,y) \) as in (18), \( k_n \to \infty, \) \( k_n/n \to 0 \) and \( k_n = o(n^{1/(2\lambda^2)}). \)

We now provide an illustration for two different copulae: survival Clayton and Logistic copulae. We remark that they are two symmetric copulae with \( \lambda > 0. \)

In particular we observe the sensitivity of \( \hat{\theta}_x \) in (20) to the sequence \( k_n \) (Figure 1). We draw the mean curve on 100 samples of size \( n = 1000 \) (full line) and the empirical standard deviation (dashed lines).

On simulations it seemed to us that for each value of \( x \) one could exhibit a range of values of \( k_n \) under which our estimate well behaved. In the following we fix \( x \) for each simulation and may vary \( k_n \). The choice of \( k_n \) does not appear to be crucial for \( \hat{\theta}_x \). In Figure 2 the mean squared error for \( \hat{\theta}_x \) is calculated on 100 samples of size \( n = 1000. \)

### 3.2. Asymptotic independent case

We say that \( X \) and \( Y \) are asymptotically independent if \( \lambda = R(1,1) = 0. \) In terms of copula this means that \( C(u,u) = 1 - 2(1-u) + o(1-u), \) for \( u \to 1. \) The problem, with respect to Section 3.1, is that \( g_X(x) = \frac{R(x,1)}{R(1,1)} \) and \( g_Y(y) = \frac{R(1,y)}{R(1,1)} \) have no sense as \( \lambda = 0 \) and \( R(x, y) = x + y - l(x,y) = 0, \) \( \forall x, y. \)

We thus need to introduce a second-order refinement of condition in (8). More precisely, as in Draisma et al. (2004), we shall assume that:
\[
\lim_{t \to 0} \frac{C^*(tx,ty) - C^*(t,t)}{q(t)} := Q(x,y),
\]  
(21)
for all $x, y \geq 0$, $x + y > 0$, where $q_1$ is some positive function and $Q$ is neither a constant nor a multiple of $G$. Moreover we assume that convergence in (21) is uniform on $\{x^2 + y^2 = 1\}$. Let $q(t) := \mathbb{P}[1 - F_X(X) < t, 1 - F_Y(Y) < t]$ and $q^{-1}$ its inverse function. Then, using (21), we obtain the following consistency result for $\hat{G}$, $\hat{g}_X$ and $\hat{g}_Y$:

**Proposition 3.1** Suppose (8) and (21) hold. We assume $\lim_{t \to 0} q(t)/t = \lambda = 0$. Then, for a sequence $k_n$ such that $a_n := n q(k_n/n) \to \infty$ (this implies $k_n \to \infty$), $k_n/n \to 0$, $\sqrt{a_n} q_1(q^{-1}(a_n/n)) \to 0$, it holds that

$$
\psi_n \sup_{0 < x, y \leq 1} |\hat{G}(x, y) - G(x, y)| \xrightarrow{P} 0,
$$

Figure 1: Estimator for $\theta$, $(k, \hat{\theta}_x)$ (left) $x = 0.07$, survival Clayton copula with parameter 1 (right) $x = 5$, Logistic copula with parameter 0.5

Figure 2: Mean squared error for $\hat{\theta}_x$ (left) $x = 0.07$, survival Clayton copula with parameter 1 (right) $x = 5$, Logistic copula with parameter 0.5
\[ \psi_n \sup_{0 < x \leq 1} |\hat{g}_X(x) - g_X(x)| \xrightarrow[p]{n \to \infty} 0, \quad \psi_n \sup_{0 < y \leq 1} |\hat{g}_Y(y) - g_Y(y)| \xrightarrow[p]{n \to \infty} 0, \]

with \( \psi_n << \sqrt{n} \), \( \hat{g}_X(x) \), \( \hat{g}_Y(y) \) and \( \hat{G}(x, y) \) as in (18).

Details of the proof are postponed to the Appendix. It is mainly based on Lemma 6.1 in Draisma et al. (2004).

In Proposition 3.2 below, by assuming some regularity properties on \( C \), we deduce a specific form for \( G \), \( g_X \), \( g_Y \) and \( \theta \).

**Proposition 3.2** If \( \lambda = 0 \) and \( C \) is a twice continuously differentiable copula with the determinant of the Hessian matrix of \( C \) at \( (1, 1) \) different to zero, then

\[ \lim_{u \to 1} \frac{C^*(x(1 - u), y(1 - u))}{C^*(1 - u, 1 - u)} = xy, \quad \forall \ x, y > 0, \]

\( g_X(x) = g_Y(x) = x \) and \( \theta = 2 \).

Details of the proof will be omitted here. The main ingredient is the second-order development of copula \( C \).

The assumptions of Proposition 3.2 are satisfied for a large class of asymptotic independent copulae: Ali Mikhail-Haq, Frank, Clayton with \( a \geq 0 \), Independent and Farlie-Gumbel-Morgenstern copulae. An example of a non symmetric copula that satisfies the assumptions of Proposition 3.2 is \( C(u, v) = xy + \frac{1}{3}(1 - |2x - 1|)(1 - (2y - 1)^2) \). This type of asymmetric copula is proposed in Benth and Kettler (2011) to model the evolution of price spread between electricity and gas prices.

We introduce some examples of asymptotic independent copulae that do not satisfy the assumptions of Proposition 3.2.

We consider the Ledford and Tawn’s model (e.g. see Ledford and Tawn, 1996): \( 2u - 1 + C(1 - u, 1 - u) = (1 - u)^\eta L(1 - u) \), with \( L \) a slowly varying function at zero and \( \eta \in (0, 1] \). Then, for \( \eta > 1/2 \), \( \lim_{u \to 1} (C(1, 1) - C(1 - u, 1) - C(1, 1 - u) - C(1 - u, 1 - u))/((1 - u)^2) = \infty \).

Thus \( \frac{\partial^2 C}{\partial u \partial v} \) does not exist at the point \( (1, 1) \). In particular this is the case of the Gaussian Copula with correlation parameter \( \rho > 0 \). However, from Theorem 5.3 in Juri and Wüthrich (2004), for a Gaussian Copula with \(| \rho | < 1 \) it holds that \( \lim_{u \to 1} C_{uu}(x, y) = xy \) for \( (x, y) \in [0, 1]^2 \).

Let \( C(u, v) = xy - \frac{1}{8}(1 - |2x - 1|)(1 - (2y - 1)^2) \), (for further details see Benth and Kettler, 2011). In this case \( \frac{\partial^2 C}{\partial u \partial v}(1, 1) = 0 \). However we can calculate the limit in (8), and using (10) we obtain

\[ G(x, y) = xy^2, \quad g_X(x) = x, \quad g_Y(y) = y^2, \quad \theta = 3. \]

We now provide an illustration for a Clayton copula. In particular we observe the sensitivity of \( \hat{\theta}_x \) in (20) to the sequence \( k_n \) (Figure 3). We draw the mean curve on 100 samples of size \( n = 1000 \) (full line) and the empirical standard deviation (dashed lines). Furthermore the mean squared error for \( \hat{\theta}_x \) is calculated on 100 samples of size \( n = 1000 \).
4. Estimating tail distributions

4.1. Estimating the tail of univariate distributions

The estimation of the tail of bivariate distributions requires first the estimation of one-dimensional tail (McNeil, 1999; El-Aroui and Diebolt, 2002). Fix a threshold \( u \) and define \( F_u(x) = \mathbb{P}[X \leq x \mid X > u] \). Let \( X_1, X_2, \ldots \) be a sequence of i.i.d random variables with unknown distribution function \( F \) and \( \hat{F}_X(u) \) the empirical distribution function evaluated at the threshold \( u \). Recall that the univariate tail may be estimated by

\[
\hat{F}^{*}(x) = (1 - \hat{F}_X(u))V_{\hat{\xi}, \hat{\sigma}}(x - u) + \hat{F}_X(u), \quad \text{for } x > u, \tag{22}
\]

where \( \hat{\xi}, \hat{\sigma} \) are the maximum likelihood estimators (MLE) based on the excesses above \( u \). Using (22) we get the estimator, proposed by Smith (1987)

\[
1 - \hat{F}^{*}(y) = \begin{cases} 
\frac{N}{n} \left( 1 - \hat{\xi} \frac{(y-u)}{\hat{\sigma}} \right)^{\frac{1}{\hat{\xi}}}, & \text{if } \hat{\xi} \neq 0, \\
\frac{N}{n} (e^{-(y-u)})^{\frac{1}{\hat{\xi}}}, & \text{if } \hat{\xi} = 0, 
\end{cases} \tag{23}
\]

with \( u < y < \infty \) (if \( \hat{\xi} \leq 0 \)) or \( u < y < \frac{\hat{\sigma}}{\hat{\xi}} \) (if \( \hat{\xi} > 0 \)) and \( N \) the random number of excesses above the threshold.

4.2. Estimating the tail of bivariate distributions

In this section we present the main construction of this paper. We propose indeed a POT procedure in order to estimate the two-dimensional distribution function \( F(x, y) \). Asymptotic properties for this estimator are stated and proved in Section 6.

This construction generalizes the one-dimensional POT construction stated in Section 4.1. Let \( X \) and \( Y \) be two real valued random variables with different...
continuous marginal distributions \( F_X \) and \( F_Y \). The structure of dependence between \( X \) and \( Y \) is represented by copula \( C \).

Construction of the tail estimator:

Given a high threshold \( u \) and \( u_Y := F_Y^{-1}(F_X(u)) \), we introduce the distribution of excesses: \( F_u(x, y) := \Pr[X - u \leq x, Y - u_Y \leq y \, | \, X > u, Y > u_Y] \). Using (3) for large value of \( u \) and \( x > u, y > u_Y \), we can approximate \( F(u, y) \) and \( F(x, u_Y) \) as

\[
F_1^*(u, y) = e^{\{-l(-\log(F_X(u)), -\log(F_Y(y)))\}}, \tag{24}
\]

\[
F_2^*(x, u_Y) = e^{\{-l(-\log(F_X(x)), -\log(F_Y(u_Y)))\}}, \tag{25}
\]

where \( l \) is the stable tail dependence function defined by (13). We recall that behind approximations (24)-(25), in order to avoid significant bias, we suppose that the data structure is characterized by dependence (or perfect independence) in the lateral regions \([-\infty, x] \times [-\infty, u_Y] \) and \([-\infty, u_X] \times [-\infty, y] \).

From Theorem 2.1 we now know that, for \( u \) around \( x_F \), we can approximate the distribution of excesses with \( C^*G \). So we obtain, for \( x > u, y > u_Y \),

\[
F^*(x, y) = (\overline{F}(u, u_Y)) \cdot C^*G \left( 1 - g_X(1-V_{\xi_X, \sigma_X}(x-u)), 1 - g_Y(1-V_{\xi_Y, \sigma_Y}(y-u_Y)) \right)
+ F_1^*(u, y) + F_2^*(x, u_Y) - F(u, u_Y). \tag{26}
\]

Then, we estimate \( F(u, u_Y) \) and \( \overline{F}(u, u_Y) \) in (26) from the data \( \{X_i, Y_i\}_{i=1,...,n} \), using the empirical distribution estimates

\[
\hat{F}(u, u_Y) = \frac{1}{n} \sum_{i=1}^{n} 1_{\{X_i \leq u, Y_i \leq u_Y\}}, \quad \overline{\hat{F}}(u, u_Y) = \frac{1}{n} \sum_{i=1}^{n} 1_{\{X_i > u, Y_i > u_Y\}}. \tag{27}
\]

From (24)-(25) and using the non parametric estimator (16) we obtain

\[
\hat{F}_1^*(u, y) = \exp\{-\hat{l}(-\log(\hat{F}_X(u)), -\log(\hat{F}_Y(y)))\}, \tag{28}
\]

\[
\hat{F}_2^*(x, u_Y) = \exp\{-\hat{l}(-\log(\hat{F}_X^*(x)), -\log(\hat{F}_Y(u_Y)))\}, \tag{29}
\]

where \( \hat{F}_X(u) \) and \( \hat{F}_Y(u_Y) \) are the empirical univariate estimators evaluated at respective thresholds and \( \hat{F}_X^*(x) \) and \( \hat{F}_Y^*(u_Y) \) are one-dimensional POT tail estimators of the marginal distribution functions, defined by (22). Now, using (27), (28) and (29), we can approximate \( F^*(x, y) \), for \( x > u, y > u_Y = F_Y^{-1}(F_X(u)) \) and \( u \) large, by

\[
\hat{F}^*(x, y) = \left( \frac{1}{n} \sum_{i=1}^{n} 1_{\{X_i > u, Y_i > u_Y\}} \right) (1 - \hat{g}_X(1-V_{\xi_X, \sigma_X}(x-u))
- \hat{g}_Y(1-V_{\xi_Y, \sigma_Y}(y-u_Y)) + \hat{G}(1-V_{\xi_X, \sigma_X}(x-u), 1-V_{\xi_Y, \sigma_Y}(y-u_Y))
+ \hat{F}_1^*(u, y) + \hat{F}_2^*(x, u_Y) - \frac{1}{n} \sum_{i=1}^{n} 1_{\{X_i \leq u, Y_i \leq u_Y\}}. \tag{30}
\]

12
where \( \hat{\xi}_X, \hat{\sigma}_X \) (resp. \( \hat{\xi}_Y, \hat{\sigma}_Y \)) are MLE based on the excesses of \( X \) (resp. \( Y \)). Finally we remark that the second threshold in (30) depends on the unknown marginal distribution functions \( F_X \) and \( F_Y \). Then, in order to compute in practice \( \hat{F}^*(x,y) \), we propose to estimate \( u_Y \) by \( \hat{u}_Y = F_Y^{-1}(\hat{F}_X(u)) \), with \( \hat{F}_X(u) = \frac{1}{n} \sum_{i=1}^n 1_{\{X_i \leq u\}} \) and \( \hat{F}_Y^{-1} \) the empirical quantile function of \( Y \).

So we obtain, from (30), the tail estimator for the two-dimensional distribution function for \( x > u \) and \( y > \hat{u}_Y \):

\[
\hat{F}^*(x,y) = \left( \frac{1}{n} \sum_{i=1}^n 1_{\{X_i > u, Y_i > \hat{u}_Y\}} \right) (1 - \tilde{g}_X(1 - V_{\hat{\xi}_X, \hat{\sigma}_X}(x - u))) \\
- \tilde{g}_Y(1 - V_{\hat{\xi}_Y, \hat{\sigma}_Y}(y - \hat{u}_Y)) + \hat{G}(1 - V_{\hat{\xi}_X, \hat{\sigma}_X}(x - u), 1 - V_{\hat{\xi}_Y, \hat{\sigma}_Y}(y - \hat{u}_Y)) \\
+ \hat{F}_1^*(u, y) + \hat{F}_2^*(x, \hat{u}_Y) - \frac{1}{n} \sum_{i=1}^n 1_{\{X_i \leq u, Y_i \leq \hat{u}_Y\}},
\]

(31)

In the case with same marginal distributions we have a particular case of (30), with the same threshold \( u \) for \( X \) and \( Y \), and we do not need to estimate the second threshold.

**Remark 3** Note that \( \hat{F}^*(x,y) \) in (31), is only valid for \( x > u \) and \( y > \hat{u}_Y \), when \( u \) is large enough. The expression large enough is a fundamental problem of the POT method. The choice of the threshold \( u \) is indeed a compromise: \( u \) has to be large for the GPD approximation to be valid, but if it is too large, the estimation of the parameters \( \xi_X, \xi_Y \) and \( \sigma_X, \sigma_Y \) will suffer from a lack of observations over the thresholds. The compromise will be explained in Sections 5 and 6.

### 5. Convergence results in the univariate case

In order to study asymptotic properties of our bivariate tail estimator we present in this section some slight modifications of one-dimensional convergence results in Smith (1987; Theorems 3.2 and 8.1). Incidentally we get asymptotic confidence intervals for the unknown theoretical univariate function \( F(x) \), using Theorem 5.1. From now on we assume that the tail of \( F \) decays like a power function, i.e. is in the domain of attraction of Fréchet i.e. \( F(x) = x^{-\alpha}L(x) \) for some slowly varying function \( L(x) \), with \( \alpha > 0 \). As in Smith (1987), Section 3, we shall assume that \( L \) satisfies the following condition

- **SR2**: \( \frac{L(tx)}{L(x)} = 1 + k(t)\phi(x) + o(\phi(x)) \), as \( x \to \infty \), \( \forall t > 0 \),

where \( \phi(x) > 0 \) and \( \phi(x) \to 0 \) as \( x \to \infty \). Let \( R_\rho \) be the set of \( \rho \)-regularly varying functions. Condition SR2 implies, excluding trivial cases, \( \phi \in R_\rho \), for some \( \rho \leq 0 \), and \( k(t) = c h_\rho(t) \), with \( h_\rho(t) = \int_t^\infty u^{\rho-1}du \); (for more details see Section 3 in Smith, 1987 or Goldie and Smith, 1987).
The study of the asymptotic properties of the maximum likelihood estimators of the scale and shape parameters of the generalized Pareto distribution in the POT method has received attention in the literature. For instance asymptotic normality of $\hat{\xi}$ and $\hat{\sigma}$, in the case of random threshold in the POT procedure is studied in depth in Drees et al. (2004). Smith (1987) examines a slightly different version of the MLE’s that is based on the excesses over a deterministic threshold and on the second-order Condition SR2. For details about the difference between these two approaches see, for instance, Remark 2.3 in Drees et al. (2004). In this paper we follow the approach proposed in Smith (1987). In particular Theorems 3.2. and 8.1. in Smith (1987) are written conditionally on $N = m_n$, with $N$ denoting the number of excesses above the threshold. In practice we work with some deterministic threshold $u$ and $N$ is considered as random (see Remark 1 in Section 1). Therefore we give the version of Theorem 3.2 in Smith (1987) (resp. Theorem 8.1), Corollary 5.1 (resp. Corollary 5.2), unconditionally on $N$.

**Corollary 5.1** Suppose $L$ satisfies SR2. Let $n$ be the sample size and $u_n := f(n)$ the threshold, such that $f(n) \to \infty$, for $n \to \infty$. Let $N = N_n$ denote the random number of excesses of $u_n$. We define $\xi = -\alpha^{-1}$ and $\sigma_n = f(n) \alpha^{-1}$. If
\[
n(1 - F(u_n)) \xrightarrow{n \to \infty} \infty,
\]
\[
\sqrt{n(1 - F(u_n))} c \phi(u_n) \xrightarrow{n \to \infty} \mu(\alpha - \rho),
\]
then there exists, with probability 1, a local maximum $(\hat{\sigma}_n, \hat{\xi}_n)$ of the GPD log likelihood function, such that
\[
\sqrt{N} \left( \frac{\hat{\sigma}_n}{\hat{\xi}_n} - 1 \right) - \frac{d}{n \to \infty} \mathcal{N} \left( \begin{pmatrix} \frac{\mu(1-\xi)(1+2\xi\rho)}{1-\xi+\xi\rho} - (1-\xi) \xi(1-\xi^2) \\ \frac{\mu(1-\xi)(1+\rho)}{1-\xi+\xi\rho} - (1-\xi) \xi(1-\xi^2) \end{pmatrix} \right).
\]

**Proof:** If (32) and (33) hold then $N(n(1 - F(u_n)))^{-1} \xrightarrow{p} 1$, and (3.2) in Smith (1987) holds in probability, i.e.
\[
\frac{\sqrt{N} c \phi(u_n)}{\alpha - \rho} = \xrightarrow{\alpha - \rho} \mu \in (-\infty, \infty).
\]

Hence we conclude with a Skorohod-type construction of probability spaces on which (3.2) in Smith (1987) holds almost surely. □

**Corollary 5.2** Suppose all the assumptions of Corollary 5.1 are satisfied. Let $n$ be the sample size, $u_n := f(n) \to \infty$ and $z_n := f(n) \to \infty$, for $n \to \infty$, such that $(z_n)^{-s} \phi(u_n(z_n)) \xrightarrow{s \in [0, 1]} 1$, for $n \to \infty$ and $s \in [0, 1]$. Let $N = N_n$ denote the random number of excesses above $u_n$. If
\[
\frac{\log(z_n)}{\sqrt{n(1 - F(u_n))}} \xrightarrow{n \to \infty} 0,
\]

(34)
then
\[
\sqrt{N} \frac{1 - \hat{F}^*(\hat{f}(n) f(n))}{1 - F(\hat{f}(n) f(n))} - 1 \xrightarrow{\text{d}} N(\nu, \tau^2),
\]
where \(\hat{F}^*\) is as in (23), \(\nu = 0\) if \(\rho = 0\), \(\nu = \frac{\mu_0(\alpha + 1)(1 + \rho)}{1 + \alpha - \rho}\) for \(\rho < 0\) and \(\tau^2 = \alpha^2(1 + \alpha)^2\).

**Proof:** If (32), (33) and (34) hold, then (8.7), (8.8) and (8.11) in Smith (1987) hold in probability, i.e
\[
\left[ \frac{N}{n(1 - F(u_n))} - 1 \right] \xrightarrow{\text{p}} 0.
\]
We conclude as for Corollary 5.1. □

Note that, in simple cases, we often have \(\phi(x) = x^p\); in which case \(\frac{(z_n)^\rho \phi(u_n(z_n)^p)}{\phi(u_n)} \to 1\), for \(n \to \infty\), is automatic satisfied. From Corollary 5.2 the following result can be obtained.

**Theorem 5.1** Assume that all the assumptions of Corollary 5.2 are satisfied. We use the same notation. If
\[
(z_n)^\alpha (n - F(u_n)))^{-1/2} \xrightarrow{n \to \infty} 0,
\]
then
\[
\sqrt{N} \frac{1 - \hat{F}^*(\hat{f}(n) f(n))}{1 - F(\hat{f}(n) f(n))} - 1 \xrightarrow{\text{d}} N(\nu, \tau^2),
\]
where \(\hat{F}\) is the univariate empirical survival function, \(\hat{F}^*\) is as in (23), \(\nu = 0\) if \(\rho = 0\), \(\nu = \frac{\mu_0(\alpha + 1)(1 + \rho)}{1 + \alpha - \rho}\) for \(\rho < 0\) and \(\tau^2 = \alpha^2(1 + \alpha)^2\).

The proof of Theorem 5.1 is postponed to the Appendix. As a byproduct, from (36) it is possible to construct in practice asymptotic confidence intervals for \(F(\hat{f}(n) f(n))\).

### 6. Convergence results in the bivariate case

In this section we provide our main result: the consistency property of our bivariate tail estimator (31) with convergence rate. We consider:

**Remark 4** Let \(n\) be the sample size. We choose, from Theorem 2.1,
\[
u_1 = \frac{\mu_0(\alpha + 1)(1 + \rho)}{1 + \alpha - \rho} \quad \text{for} \quad \rho < 0 \quad \text{and} \quad \tau^2 = \alpha^2(1 + \alpha)^2.
\]

The proof of Theorem 5.1 is postponed to the Appendix. As a byproduct, from (36) it is possible to construct in practice asymptotic confidence intervals for \(F(\hat{f}(n) f(n))\).
Remark 5 As in Section 4.2 in the following we propose to estimate the second threshold \( \tilde{f}_2(n) \) by \( \hat{f}_2(n) := \hat{F}_{Y}^{-1}(\hat{F}_X(\tilde{f}_1(n))) \), with \( \hat{F}_X(\tilde{f}_1(n)) = \frac{1}{n} \sum_{i=1}^{n} 1_{\{X_i \leq \tilde{f}_1(n)\}} \) and \( \hat{F}_Y^{-1} \) the empirical quantile function of \( Y \).

In the following we state and prove separately our consistency result in the asymptotic dependent case (Theorem 6.1) and in the asymptotic independent one (Theorem 6.2).

6.1. Asymptotic dependent case

The proof of Theorem 6.1 below, makes use of a result by Einmahl et al. (2006) which specifies the asymptotic behavior of \( \hat{l}(x,y) \) uniformly in \( 0 \leq x, y \leq 1 \) and provides a convergence rate (see Theorem C in Appendix). More precisely in the asymptotic dependent case, using (18) and applying Corollary 3.1, we obtain the following main result:

**Theorem 6.1** Suppose \( F_X \) and \( F_Y \) belong to the maximum domain of attraction of Fréchet, \( L_X, L_Y \) satisfy Condition SR2. Assume that \( \lambda > 0 \) and that the assumptions of Theorem 2.1 and Corollary 3.1 are satisfied. If sequences \( f_1(n), f_2(n), \tilde{f}_1(n), \tilde{f}_2(n), \) defined by Remark 4, satisfy conditions of Theorem 5.1 then

\[
\left| k_n F^*(x, y) - \hat{F}^*(x, y) \right| \xrightarrow{p} 0, \quad n \to \infty, \tag{37}
\]

with \( x_n = \tilde{f}_1(n)f_1(n), \ y_n = \tilde{f}_2(n)f_2(n) \). Moreover if \( \hat{f}_2(n) \) satisfies conditions of Theorem 5.1 in probability then

\[
\left| k_n F^*(x, \hat{y}_n) - \hat{F}^*(x, \hat{y}_n) \right| \xrightarrow{p} 0, \quad n \to \infty, \tag{38}
\]

with \( \hat{y}_n = \hat{f}_2(n)f_2(n) \). In (37)-(38) we have \( k_n \to \infty, \ k_n/n \to 0, \ k_n/N_X \xrightarrow{p} 0, \ k_n/N_Y \xrightarrow{p} 0, \ k_n = o(n^{\frac{1-2\alpha}{1+2\alpha}}), \ \alpha > 0 \).

The proof of Theorem 6.1 is postponed to the Appendix.

**Remark 6** Let us study, on a class of examples, the assumption of Theorem 6.1. First if we suppose that the function \( \phi(x) \) in Condition SR2 (Section 5) has the general form \( \phi(x) = x^p \), with \( p \leq 0 \), then

\[
(z_n)^{-p} \phi(\hat{f}_2(n)(z_n)^p) / \phi(\hat{f}_2(n)) = 1, \quad \forall \ s \in [0,1].
\]

For instance this is the case of Burr or Fréchet univariate distributions. Furthermore if we assume that \( F_Y \) belongs to the maximum domain of attraction of Fréchet (i.e. \( F_Y(y) = y^{-\alpha}L(y) \)), \( F_Y \) has positive density \( f_Y \in \mathbb{R}_{-1-\alpha} \) and \( \hat{f}_2(n) \) satisfies conditions in (32)-(35) then also the estimated second threshold \( \tilde{f}_2(n) \) satisfies, in probability, conditions in (32)-(35).
We remark indeed that \( \hat{F}_X(\bar{f}_1(n)) \) is a high quantile within the sample (see Embrechts et al., 1997), i.e. \( \hat{F}_X(\bar{f}_1(n)) \xrightarrow{p} 1 \) and \( n(1-\hat{F}_X(\bar{f}_1(n))) \xrightarrow{p} \infty \).

Then, using Theorem 6.4.14 in Embrechts et al. (1997) and a Skorohod-type construction of probability spaces we obtain \( \hat{f}_2(n) (\bar{f}_2(n))^{-1} \xrightarrow{p} 1 \).

Furthermore, using Condition SR2,

\[
\frac{\hat{F}_Y(\bar{f}_2(n))}{\hat{F}_Y(\bar{f}_2(n))} = \frac{\hat{f}_2(n)^{-\alpha} L(\bar{f}_2(n)) + \alpha(n(\bar{f}_2(n)) + o(\bar{f}_2(n)))}{\hat{f}_2(n)^{-\alpha} L(\bar{f}_2(n))}
\]

Using properties of \( k \) and \( \phi \) (see Section 5) we obtain \( \hat{f}_2(n) \xrightarrow{p} 1 \).

Then \( \hat{f}_2(n) \) satisfies, in probability, condition in (32):

\[
n(1 - F_Y(\bar{f}_2(n))) = \frac{\hat{F}_Y(\hat{f}_2(n))}{\hat{F}_Y(\hat{f}_2(n))} n(1 - F_Y(\bar{f}_2(n))) \xrightarrow{p} \infty
\]

The proof for conditions in (33)-(35) is completely analogue to that of condition in (32).

6.2. Asymptotic independent case

As noticed in Section 3.2 in the asymptotic independent case we need to introduce a second-order refinement of condition in (8). Under condition in (21) we obtain the following main result:

**Theorem 6.2** Suppose \( F_X \) and \( F_Y \) belong to the maximum domain of attraction of Fréchet, \( L_X \), \( L_Y \) satisfy Condition SR2. Assume that the assumptions of Theorem 2.1, Proposition 3.1 and Corollary 7.1 are satisfied. If sequences \( f_1(n), f_2(n), \bar{f}_1(n), \bar{f}_2(n) \), defined by Remark 4, satisfy conditions of Theorem 5.1 then

\[
|\sqrt{a_n}(F^*(x_n, y_n) - \hat{F}^*(x_n, y_n))| \xrightarrow{p} 0, \quad (39)
\]

where \( x_n = \bar{f}_1(n)f_1(n), y_n = \bar{f}_2(n)f_2(n) \). Moreover if \( \hat{f}_2(n) \) satisfies conditions of Theorem 5.1 in probability then

\[
|\sqrt{a_n}(F^*(x_n, \hat{y}_n) - \hat{F}^*(x_n, \hat{y}_n))| \xrightarrow{p} 0, \quad (40)
\]

with \( \hat{y}_n = \hat{f}_2(n)f_2(n) \). In (39)-(40) we have \( a_n = n q(k_n/n) \rightarrow \infty \) (this implies \( k_n \rightarrow \infty \), \( k_n/n \rightarrow 0 \), \( \sqrt{a_n} q_1(q^-(a_n/n)) \rightarrow 0 \), \( k_n/NX \xrightarrow{p} 0 \), \( k_n/Y \xrightarrow{p} 0 \), and \( k_n = o(n^{\frac{\alpha}{2+\alpha}}) \), for some \( \alpha > 0 \).

The proof of Theorem 6.2 is postponed to the Appendix.
7. Illustrations with real data

In this section we present four real cases (see Figures 4-5) for which we estimate bivariate tail probabilities to illustrate the finite sample properties of our estimator. We analyze the stability of our estimation compared to the one of \( \hat{F}_{1}^* \), as well the estimation of parameter \( \theta \) of these real cases.

![Figure 4: Logarithmic scale (left) ALAE versus Loss; (right) Storm damages.](image)

![Figure 5: (left) Wave Height (m) versus Surge (m); (right) Wave heights versus Water level.](image)

We consider the Loss–ALAE data (for details see Frees and Valdez, 1998). Each claim consists of an indemnity payment (the loss, \( X \)) and an allocated loss adjustment expense (ALAE, \( Y \)). We estimate \( F(2 \times 10^5, 10^5) \). The empirical probability, defined by (27), is 0.9506667 and the survival empirical probability is 0.006 (for a comparison using the Ledford and Tawn’s model see Beirlant et al., 2011). Figure 6 shows the sensitivity of \( \hat{\theta} \) and \( \hat{F}^* \) to the sequence \( k_n \) and provides a comparison with the estimator \( \hat{F}_{1}^* \).
We now consider an example from storm insurance: aggregate claims of motor policies ($Y$) and aggregate claims of household policies ($X$) from a French insurance portfolio for 736 storm events (for a detailed description see Lescourret and Robert, 2006). We estimate $F(8000, 950)$. The empirical probability is 0.96875 and the survival empirical probability is 0.014. The stability of our estimation compared to the one of $\hat{F}_1^*$, as well the estimation of parameter $\theta$ are presented in Figure 7.

We study the wave surge data comprising 2894 bivariate events that occurred during 1971 – 1977 in Cornwall (England) (for details see Coles and Tawn, 1994 or Ramos and Ledford, 2009). We estimate $F(8.32, 0.51)$. The empirical probability is 0.9903 and the survival empirical probability is 0.00069. The sensitivity of $\hat{\theta}$ and $\hat{F}^*$ to the sequence $k_n$ and the estimation of $\theta$ are presented in Figure 8.
Finally we analyze the **Wave height versus Water level data**, recorded during 828 storm events spread over 13 years in front of the Dutch coast near the town of Petten (for details see Draisma *et al.*, 2004). We estimate $F(5.93, 1.87)$. The empirical probability is 0.97584 and the survival empirical probability is 0.00604. The sensitivity of $\hat{\theta}$ and $\hat{F}^*$ to the sequence $k_n$ and the estimation of $\theta$ are presented in Figure 9. From Draisma *et al.* (2004) it seems that the coefficient $\eta$ of Ledford and Tawn’s model is smaller than 1, then it is plausible to assume asymptotic independence between the wave heights and the water level. Analogously, in our model the estimated parameter $\hat{\theta}$ is greater than one (see Figure 9).
Appendix: proofs and auxiliary results

Proof [Proposition 2.1]:

We know that
\[ C_u^{ap}(x, y) = 1 - \frac{C^*(1 - F_{X,u}(x), 1 - u)}{C^*(1 - u, 1 - u)} - \frac{C^*(1 - u, 1 - F_{Y,u}(y))}{C^*(1 - u, 1 - u)} + \frac{C^*(1 - F_{X,u}(x), 1 - F_{Y,u}(y))}{C^*(1 - u, 1 - u)}. \]

Then
\[ \lim_{u \to 1} C_u^{ap}(x, y) = \lim_{u \to 1} \left[ x + y - 1 + \frac{C^*(1 - F_{X,u}(x), 1 - F_{Y,u}(y))}{C^*(1 - u, 1 - u)} \right]. \]

We introduce the following lemma.

Lemma A (Charpentier and Juri, 2006; Lemma 6.1) Suppose that the random vectors \((X_n, Y_n)\) have continuous, strictly increasing marginals and are such that \(\lim_{n \to \infty} (X_n, Y_n) = (X, Y)\) in distribution for some \((X, Y)\). Then
\[ \lim_{n \to \infty} ||C_n - C||_\infty = 0, \]
where \(C_n\) and \(C\) denote the copulas of \((X_n, Y_n)\) and \((X, Y)\), respectively.

Let \((X, Y)\) have distribution function \(C\). Note that
\[ P[X > x(1 - u) | X > u, Y > u] = \frac{C^*(1 - x(1 - u), 1 - u)}{C^*(1 - u, 1 - u)}, \]
\[ P[Y > y(1 - u) | X > u, Y > u] = \frac{C^*(1 - u, 1 - y(1 - u))}{C^*(1 - u, 1 - u)}, \]
\[ P[X > x(1 - u), Y > y(1 - u) | X > u, Y > u] = \frac{C^*(1 - x(1 - u), 1 - y(1 - u))}{C^*(1 - u, 1 - u)}. \]

The distributions in (42)-(44) are respectively the survival conditional distributions of \(X_{1-u}, Y_{1-u}\) and \(\left(\frac{X}{1-u}, \frac{Y}{1-u}\right)\), given that \(X > u\) and \(Y > u\). Since \(\partial C^*(1 - u, 1 - v)/\partial u < 0\) and \(\partial C^*(1 - u, 1 - v)/\partial v < 0\), for all \(u, v \in [0, 1]\), it follows that the distributions in (42)-(43) are continuous and strictly increasing. By hypothesis, we have
\[ \lim_{u \to 1} \frac{C^*(x(1 - u), y(1 - u))}{C^*(1 - u, 1 - u)} = G(x, y), \text{ for all } x, y > 0, \]
implying that the expressions in (42)-(43) respectively converge to \(g_X(1 - x)\) and \(g_Y(1 - y)\) as \(u \to 1\), with \(g_X(x) := G(x, 1)\), \(g_Y(y) := G(1, y)\).

Since copulas are invariant under strictly increasing transformations of the underlying variables, it follows that we can use the conditional distributions in
From (41), instead of \( F_{X,u} \) and \( F_{Y,u} \), to construct \( C_{u}^{(p)}(x,y) \). Then, from (41) and using Lemma A, we have

\[
limit_{u \to 1} C_{u}^{(p)}(x,y) = \lim_{u \to 1} \left[ x + y - 1 + \frac{C^{*}(g^{-1}_{X}(1-x)(1-u), g^{-1}_{Y}(1-y)(1-u))}{C^{*}(1-u, 1-u)} \right] = x + y - 1 + G(g^{-1}_{X}(1-x), g^{-1}_{Y}(1-y)).
\]

As in the proof of Theorem 3.1 in Charpentier and Juri (2006), the limit in (45) implies that there is a \( \theta > 0 \) such that \( G \) is homogeneous of order \( \theta \), i.e. for all \( t, x, y > 0 \),

\[
G(tx, ty) = t^{\theta} G(x, y).
\]

By a discussion of the general solution of functional (46) we obtain the explicit form of \( G \):

\[
G(x, y) = \begin{cases} 
   x^{\theta} g_{X}(\frac{x}{x}) & \text{for } \frac{x}{x} \in [0, 1], \\
   y^{\theta} g_{X}(\frac{y}{y}) & \text{for } \frac{y}{y} \in (1, \infty).
\end{cases}
\]

For this part of the proof we refer the interested reader to Theorem 3.1 in Charpentier and Juri, (2006).

**Proof [Theorem 2.1]:**

From (11) we obtain the existence of \( a_{1}(\cdot) \) and \( a_{2}(\cdot) \) such that, for \( p := u + x a_{1}(u) \) and \( q := u + y a_{2}(u) \)

\[
V_{\xi_{1},1}(x) = \lim_{u \to x_{F_{X}}} 1 - \frac{1 - F_{X}(p)}{1 - F_{X}(u)} = \lim_{u \to x_{F_{X}}} P[X \leq p|X > u],
\]

\[
V_{\xi_{2},1}(y) = \lim_{u \to y_{F_{Y}}} 1 - \frac{1 - F_{Y}(q)}{1 - F_{Y}(u_{Y})} = \lim_{u \to y_{F_{X}}} P[Y \leq q|Y > u_{Y}].
\]

From \( Y \overset{d}{=} F_{Y}^{-1}(F_{X}(X)) \), we take \( u_{Y} = F_{Y}^{-1}(F_{X}(u)) \) and from (47)-(48), as \( u \to x_{F_{X}} \), we have

\[
1 - (1 - V_{\xi_{1},1}(x))(1 - F_{X}(u)) \sim F_{X}(u + x a_{1}(u)),
\]

\[
1 - (1 - V_{\xi_{2},1}(y))(1 - F_{Y}(F_{Y}^{-1}(F_{X}(u)))) \sim F_{Y}(F_{Y}^{-1}(F_{X}(u)) + y a_{2}(F_{Y}^{-1}(F_{X}(u)))).
\]

Then

\[
\lim_{u \to x_{F_{X}}} P \left[ \frac{X - u}{a_{1}(u)} > x, \frac{Y - F_{Y}^{-1}(F_{X}(u))}{a_{2}(F_{Y}^{-1}(F_{X}(u)))} > y \right| X > u, Y > F_{Y}^{-1}(F_{X}(u)) \right] = \lim_{u \to x_{F_{X}}} \frac{C^{*}(1 - F_{X}(u + x a_{1}(u)), 1 - F_{Y}(F_{Y}^{-1}(F_{X}(u)) + y a_{2}(F_{Y}^{-1}(F_{X}(u)))))}{C^{*}(1 - F_{X}(u), 1 - F_{Y}(F_{Y}^{-1}(F_{X}(u))))}
\]

\[
= \lim_{u \to x_{F_{X}}} \frac{C^{*}((1 - V_{\xi_{1},1}(x))(1 - F_{X}(u)), (1 - V_{\xi_{2},1}(y))(1 - F_{Y}(F_{Y}^{-1}(F_{X}(u))))}{C^{*}(1 - F_{X}(u), 1 - F_{Y}(F_{Y}^{-1}(F_{X}(u))))}
\]

\[
= \lim_{\nu \to 1} \frac{C^{*}((1 - V_{\xi_{1},1}(x))(1 - \nu), (1 - V_{\xi_{2},1}(y))(1 - \nu))}{C^{*}(1 - \nu, 1 - \nu)}. \quad (49)
\]

22
Now, if \( h := (1 - \xi_1 x)^{1/\alpha}, \) \( \xi_1 \neq 0 \) or if \( h := e^{-x}, \xi_1 = 0 \) then \( 1 - V_{\xi_1,1}(x) = V_{1,1}(h). \) So (49) becomes \( \lim_{u \to 1} C^*(V_{1,1}(h)(1 - \nu), V_{1,1}(w)(1 - \nu))/C^*(1 - \nu, 1 - \nu). \) As \( C \) satisfies hypotheses of Proposition 2.1, the above limit is equal to 
\[ G(V_{1,1}(h), V_{1,1}(w)) = G(1 - V_{\xi_1,1}(x), 1 - V_{\xi_2,1}(y)). \]
Then
\[
\lim_{u \to x} \mathbb{P} \left[ \frac{X - u}{a_1(u)} \leq x, \frac{Y - F^{-1}_X(u)}{a_2(F^{-1}_X(u))} \leq y \mid X > u, Y > F^{-1}_X(u) \right] = C^* G(1 - g_X(1 - V_{\xi_1,1}(x)), 1 - g_Y(1 - V_{\xi_2,1}(y))).
\]
Since the limit is a continuous distribution function (as \( C^* G \), \( g \) and the GPD are), (50) can be strengthened to uniform convergence (see e.g. Embrechts et al. 1997, p. 552). Then (12) follows. □

**Proof [Theorem 5.1]:**
To begin with, we work conditionally on \( N_n = m_n \). First we have to prove that
\[
\tilde{r}_{m_n} \left[ F(u_{m_n} z_{m_n}) - \tilde{F}^*(u_{m_n} z_{m_n}) \right] \xrightarrow{d} N(\nu, \tau^2), \tag{51}
\]
with
\[
\tilde{r}_{m_n} = \frac{\sqrt{m_n}}{\log(z_{m_n})} \left( 1 - \frac{\sum_{i=1}^{\infty} \mathbf{1}(X_i \leq u_{m_n} z_{m_n})}{\sum_{i=1}^{\infty} \mathbf{1}(X_i \leq u_{m_n} z_{m_n})} \right) = \frac{\sqrt{m_n}}{\log(z_{m_n})} \frac{\sqrt{m_n}}{F(u_{m_n} z_{m_n})}.
\]
To this end we need to prove that
\[
\frac{\tilde{F}(u_{m_n} z_{m_n})}{\tilde{F}(u_{m_n} z_{m_n})} \xrightarrow{p} 1, \tag{52}
\]
then, using Theorem 8.1 in Smith (1987) and the Slutsky theorem, we obtain (51). To prove (52) we use the following result:

**Proposition B (Einmahl, 1990; Corollary 1)** Let a sequence of i.i.d random variables \( X_1, X_2, \ldots \) from a distribution function \( F \). We denote with \( \{k_n\} \) an arbitrary sequence of positive numbers, such that \( k_n \leq n \) and \( k_n \to \infty \), \( \lim_{n \to \infty} k_n/n = 0 \). Let \( \{\gamma_n\} \) be a sequence of positive numbers, such that \( \lim_{n \to \infty} \gamma_n/n = \infty \), then \( \sup_{t \geq F^{-1}(1-k_n/n)} \left( \frac{n}{\gamma_n} \right) |\tilde{F}(t) - \tilde{F}(t)| \xrightarrow{p} 0. \)

We choose an arbitrary sequence \( \{k_n\} \) \( \{m_n\} \) (number of excesses on a sample of size \( n \)) such that \( m_n \leq n \), \( \lim_{n \to \infty} m_n = \infty \) and \( \lim_{n \to \infty} \frac{m_n}{n} = 0 \) (see Remark 1 in Section 1). We take \( \{\gamma_n\} \) \( \{\sqrt{m_n} \alpha_n\} \) \( n \alpha_n \) is an arbitrary sequence of positive numbers such that \( \lim_{n \to \infty} \alpha_n = \infty \). Then, using Proposition B, we have for \( u_{m_n} z_{m_n} \geq F^{-1}(1 - \frac{m_n}{n}) \)
\[
\left( \frac{n}{\sqrt{m_n} \alpha_n} \right) \left| \frac{\tilde{F}(u_{m_n} z_{m_n}) - \tilde{F}(u_{m_n} z_{m_n})}{\tilde{F}(u_{m_n} z_{m_n})} \right| \xrightarrow{p} 0.
\]
We choose \( \alpha_n \) such that for large \( n \)
\[
\exists c > 0 : \quad 0 < \frac{\sqrt{m_n} \alpha_n}{n \tilde{F}(u_{m_n} z_{m_n})} \leq c. \tag{53}
\]
23
In the Fréchet case we have $L(x) = x^\alpha F(x)$, for $\alpha > 0$ and $\forall t > 0$, $\frac{L(tx)}{L(x)} = 1 + k(t)\phi(x) + o(\phi(x))$ for $x \to \infty$. Then, using Assumptions (8.7) and (8.8) of Theorem 8.1. in Smith (1987), we obtain
\[
\frac{F(u_{mn} z_{mn})}{F(u_{mn})} = z_{mn} [1 + k(z_{mn})\phi(u_{mn}) + o(\phi(u_{mn}))].
\]
Hence $\frac{n F(u_{mn} z_{mn})}{\sqrt{m_n}}$ is equal to $\frac{n}{\sqrt{m_n}} F(u_{mn}) [z_{mn}^{-\alpha} (1 + k(z_{mn})\phi(u_{mn}) + o(\phi(u_{mn})))]
\]
which, for $n$ large, can be approximated by
\[
\sqrt{m_n} z_{mn}^{-\alpha} (1 + k(z_{mn})\phi(u_{mn}) + o(\phi(u_{mn}))). \tag{54}
\]
Assume now $\frac{(z_{mn})^\alpha}{\sqrt{m_n}} \to 0$, that is the analogue of condition in (35) conditionally on $N_n = m_n$. Then the properties of $k$ and $\phi$ ensure that the right hand side of (54) increases to infinity hence one can choose $\alpha_n$ satisfying (53). To conclude the proof, we use assumption (35) and a Skorohod type argument. □

**Proof [Theorem 6.1]:**
To prove (37) we first observe, using Corollary 3.1, Proposition 7.1 and the analogue of Kolmogorov-Smirnov Theorem in dimension 2 (e.g. see Dudley, 1966), that
\[
\sqrt{n} \left| C^* G \left(1 - g_X(1 - V_{\xi,\sigma X} (\tilde{f}_1(n) - \tilde{f}_1(n))), 1 - g_Y(1 - V_{\xi,\sigma Y} (\tilde{f}_2(n) - \tilde{f}_2(n)))\cdot \mathcal{F}(\tilde{f}_1(n), \tilde{f}_2(n)) - \hat{\mathcal{F}}(\tilde{f}_1(n), \tilde{f}_2(n))\right) \cdot C^{**} G \left(1 - \hat{g}_X(1 - V_{\xi,\sigma X} (\tilde{f}_1(n) - \tilde{f}_1(n))), 1 - \hat{g}_Y(1 - V_{\xi,\sigma Y} (\tilde{f}_2(n) - \tilde{f}_2(n)))\right) \right| \xrightarrow{n \to \infty} 0.
\]
Furthermore, $r_n \left| \frac{1}{n} \sum_{i=1}^{n} 1 \{ X_i \leq \tilde{f}_1(n), Y_i \leq \tilde{f}_2(n) \} - F(\tilde{f}_1(n), \tilde{f}_2(n)) \right| \xrightarrow{P} 0$ with $r_n << \sqrt{n}$. At last using Corollary 3.1, Theorem 5.1, we obtain convergence (37). If $\tilde{f}_2(n)$ satisfies conditions of Theorem 5.1 in probability then with the same proof structure we obtain (38). □

**Proof [Proposition 3.1]:** Under assumptions of Proposition 3.1, as in the proof of Lemma 6.1 in Draisma et al. (2004) we obtain
\[
\sup_{0 < x, y \leq 1} \sqrt{a_n} \left( \frac{1}{a_n} \sum_{i=1}^{n} 1 \{ R(X_i) > n - k_n x + 1; R(Y_i) > n - k_n y + 1 \} - G(x, y) \right)^{- W(x, y)} \xrightarrow{a.s.} 0, \tag{55}
\]
where $a_n = n q(k_n/n)$ and $W(x, y)$ is a zero-mean gaussian process with $\mathbb{E}(W(x_1, y_1) W(x_2, y_2)) = G(x_1 \wedge x_2, y_1 \wedge y_2)$. Then, in particular
\[
\psi_n \sup_{0 < x, y \leq 1} \left| \frac{1}{a_n} \sum_{i=1}^{n} 1 \{ R(X_i) > n - k_n x + 1; R(Y_i) > n - k_n y + 1 \} - G(x, y) \right| = \psi_n \sup_{0 < x, y \leq 1} \left| \tilde{G}(x, y) - G(x, y) \right| \xrightarrow{P} 0,
\]

24
with \( \psi_n \leq \alpha \sqrt{n q(k_n/n)} \) and \( \hat{G} \) as in (18). Finally for the marginals \( g_X \) and \( g_Y \) we have

\[
\psi_n \sup_{0 < x \leq 1} \left| \hat{g}_X(x) - g_X(x) \right| \xrightarrow{\mathbb{P}} 0, \quad \psi_n \sup_{0 < y \leq 1} \left| \hat{g}_Y(y) - g_Y(y) \right| \xrightarrow{\mathbb{P}} 0,
\]

with \( \hat{g}_X \) and \( \hat{g}_Y \) as in (18). \( \square \)

**Proof [Theorem 6.2]:**

Under assumptions of Theorem 6.2 and Proposition 3.1 we obtain asymptotic convergence results for \( \hat{G}(x, y), \hat{g}_X(x) \) and \( \hat{g}_Y(y) \), with convergence rate \( \psi_n \leq \alpha \sqrt{n q(k_n/n)} \) as in (18). With the same proof structure of Theorem 6.1, using Corollary 7.1 and Proposition 7.1 we obtain convergence (39). Moreover if \( \hat{f}_2(n) \) satisfies conditions of Theorem 5.1 in probability then we obtain (40). \( \square \)

**Auxiliary results**

**Theorem C (Einmahl et al. 2006; Theorem 2.2)** Assume that there exists the limit \( R(x, y) \) in (14) such that, for some \( \alpha > 0 \)

\[
\frac{1}{t} \mathbb{P}(1 - F_X(X) \leq tx, 1 - F_Y(Y) \leq ty) - R(x, y) = O(t^\alpha), \quad \text{as } t \to 0,
\]

uniformly for \( \max(x, y) \leq 1, \ x, y \geq 0 \). Let \( k_n \to \infty, \ k_n/n \to 0 \) and \( k_n = o(n^{2/\alpha}) \). If \( R_1(x, y) := \frac{\partial R(x, y)}{\partial x} \) and \( R_2(x, y) := \frac{\partial R(x, y)}{\partial y} \) are continuous then

\[
\sup_{0 < x, y \leq 1} \left| \sqrt{k_n}(\tilde{l}(x, y) - l(x, y)) + B(x, y) \right| \xrightarrow{\mathbb{P}} 0,
\]

where \( B(x, y) := W(x, y) - R_1(x, y)W_1(x) - R_2(x, y)W_2(y) \), with \( W \) a continuous mean zero Gaussian process on \([0, x] \times [0, y] \) with covariance structure \( \mathbb{E}(W(x_1, y_1)W(x_2, y_2)) = R(x_1 \wedge x_2, y_1 \wedge y_2) \) and with marginal processes defined by \( W_1(x) = W([0, x] \times [0, \infty]) \), \( W_2(y) = W([0, \infty] \times [0, y]) \).

Note that (55) is a second-order condition quantifying the speed of convergence in (14) and condition \( k_n = o(n^{2/\alpha}) \) gives an upper bound on the speed with which \( k_n \) can grow to infinity. This upper bound is related to the speed of convergence in (55) by \( \alpha \). If \( C \) is a twice continuously differentiable copula on \([0, 1]^2 \) then (55) holds for any \( \alpha \geq 1 \). Furthermore, it is easily seen that

\[
\tilde{l}(x, y) + \hat{R}(x, y) = \frac{\alpha}{k_n} \leq \frac{\alpha}{k_n}
\]

almost surely, for each \( 0 < x, y \leq 1 \), where \( \lfloor z \rfloor \) is the smallest integer \( \geq z \). Then under assumption of Theorem C we can easily obtain a gaussian approximation for \( \hat{R}(x, y) - R(x, y) \).

Note that the asymptotic variance of \( \sqrt{k_n}(\tilde{l}(x, y) - l(x, y)) \), in Theorem C, vanishes in the asymptotic independent case. Then, with \( \lambda = 0 \), we obtain:

**Corollary 7.1** Assume that, for some \( \alpha > 0 \)

\[
\frac{1}{t} \mathbb{P}(1 - F_X(X) \leq tx, 1 - F_Y(Y) \leq ty) = O(t^\alpha), \quad \text{as } t \to 0,
\]

25
uniformly for $\max(x, y) \leq 1$, $x, y \geq 0$. Let $k_n \to \infty$, $k_n/n \to 0$ and $k_n = o\left(n^{1/2}\right)$. Then it holds

$$
\sup_{0 < x, y \leq 1} \left| \sqrt{k_n} (\hat{l}(x, y) - l(x, y)) \right| \xrightarrow{p} 0, \quad n \to \infty.
$$

**Proposition 7.1** Let $V_{\xi, \sigma}(x)$ the Generalized Pareto Distribution (GPD) and $\hat{\xi}_n$, $\hat{\sigma}_n$, the maximum likelihood estimators of the parameters $\xi = -\alpha^{-1} < 0$ and $\sigma = u_n \alpha^{-1}$, in the case unconditionally on $N$. If all the conditions of Corollary 5.1 hold then

$$
p_{nx} \sup_{x \in [0, +\infty)} \left| V_{\hat{\xi}_n, \hat{\sigma}_n}(x) - V_{\hat{\xi}_n, \sigma}(x) \right| \xrightarrow{p} 0, \quad n \to \infty,
$$

where $p_{nx} \sqrt{N_x} \xrightarrow{p} 0$. Finally, applying a stochastic version of Polya’s Theorem (see Horowitz, 2001), as $V_{\xi, \sigma}(x)$ is a continuous distribution function, the convergence in (56) holds uniformly on $[0, +\infty)$.
