INSTITUT FRANÇAIS DE PONDICHÉRY
The Institut français de Pondichéry (IFP) or French Institute of Pondicherry, is a financially autonomous research institution under the dual tutelage of the French Ministry of Foreign and European Affairs (MAEE) and the French National Centre for Scientific Research (CNRS). It was established in 1955 under the terms agreed to in the Treaty of Cession between the Indian and French governments. It has three basic missions: research, expertise and training in human and social sciences and ecology in South and South-East Asia. More specifically, its domains of interest include Indian cultural knowledge and heritage (Sanskrit language and literature, history of religions, Tamil studies, ..), contemporary social dynamics (in the areas of health, economics and environment) and the natural ecosystems of South India (sustainable management of biodiversity).

Summary

The Western Ghats form a 1,600 km long escarpment that runs parallel to the southwestern coast of Peninsular India. This relief barrier, which orographically exacerbates the summer monsoon rains, is responsible for steep bioclimatic gradients that have long been recognized as one of the major ecological determinants for the forest vegetation of the region. We report here girded vegetation data at 30' lat/long (ca. 1 km) resolution that cover an area of about 70,000 km$^2$ of the southern Western Ghats, between 74 to 78° E and 8 to 16° N. These data have been extracted from: the 1:250,000 scale forest maps of South India published by the French Institute of Pondicherry (FIP), which have been digitized and simplified; the 2004 MODIS (Moderate Resolution Imaging Spectroradiometer) database, for the IGBP (International Biosphere Geosphere Programme) global vegetation Land Cover Type and Normalized Difference Vegetation Index (NDVI) of March 2004.

Key-words: Forest map, IGBP global vegetation, India, Land Cover Type, MODIS, NDVI, Western Ghats.

I. DATA SET DESCRIPTORS.

A. Data set identity. High-resolution vegetation cover data for the Southern Western Ghats of India.

B. Data set identification code. IFP_ECODATA_VEGETATION

C. Data set descriptors.

1. Originator. Ecology Department, French Institute of Pondicherry, 11 St Louis Street, 605001 Pondicherry, India (ifpeco@ifpindia.org).

2. Abstract. The Western Ghats form a 1,600 km long escarpment that runs parallel to the southwestern coast of Peninsular India. This relief barrier, which orographically exacerbates the summer monsoon rains, is responsible for steep bioclimatic gradients that have long been recognized as one of the major ecological determinants for the forest vegetation of the region. We report here gridded vegetation data at 30' lat/lon (ca. 1 km) resolution that cover an area of about 70,000 km$^2$ of the southern Western Ghats, between 74 to 78° E and 8 to 16° N. These data have been extracted from: the 1:250,000 scale forest maps of South India published by the French Institute of Pondicherry (FIP), which have been digitized and simplified; the 2004 MODIS (Moderate Resolution Imaging Spectroradiometer) database, for the IGBP (International Biosphere Geosphere Programme) global vegetation Land Cover Type and Normalized Difference Vegetation Index (NDVI) of March 2004.

D. Key words. Forest map, IGBP global vegetation, India, Land Cover Type, MODIS, NDVI, Western Ghats.

II. RESEARCH ORIGIN DESCRIPTORS.

A. Site description.

1. Site type. The Western Ghats (WG) form a mountain range that extends along the western coast of Arabian Sea and that, along with the island of Sri Lanka, is classified as one of the world biodiversity hotspots (Myers et al. 2000).
2. **Geography.** The WG cover an area of 160,000 km$^2$ and stretch for 1,600 km along the west coast of India, 40 km away on average from the shore line, from the Tapti river (21° N, state of Maharashtra) to Kanyakumari, the southernmost tip of the Indian peninsula (8° N, state of Tamil Nadu). We consider here only the southern part of the WG, i.e. an area ca. 70,000 km$^2$ between 74 to 78° E and 8 to 16° N.

3. **Habitat.** The southern WG shelter a wide array of non-equatorial tropical vegetation, from fragments of wet evergreen to dry deciduous forest habitats in various stages of degradation to mountain forests and grasslands, alternating with zones converted into agroforests, monoculture plantations and agriculture. About 4,000 species of flowering plants including 1,600 species (40%) endemic to this region have been reported (Manokaran *et al.* 1997).

4. **Geology, landform.** In the southern part of the Western Ghats, bedrock is composed of metamorphic rocks from the Precambrian shield, with a prevalence of volcano-sedimentary material north of 14° N, and gneisses with intrusive granites in the south. The more recent sediments deposits are confined to the coastal plain. The soils are ferralitic (laterites) to fersialitic (red soils), with a massive development of kaolinite as a product of rock weathering where the annual soil water balance is consistently positive (*i.e.* above 1,200 mm rainfall; Bourgeon 1989, Gunnel & Bourgeon 1997).

5. **Watersheds, hydrology.** Dozens of rivers originate in the WG, including the peninsula’s three major eastward-flowing rivers (Godavari, Krishna and Kaveri), which are important sources of drinking water, irrigation, and power.

6. **Climate.** The windward side of the WG receives heavy rains as the monsoon progresses from south to north. In the coastal plain the annual rainfall exceeds 2,000 mm, commonly reaching more than 5,000 mm near the crest of the Ghats, with local peaks even much beyond this value, like in Agumbe with regular records above 8,000 mm. To the interior region a rapid diminishing of rainfall from 2,000 mm to 900 mm is observed within a distance of 10 – 50 km. Convective rains prior to and following the monsoon, augment the total rainfall received at the transitional zone. Between the coastline and the crest of the Ghats, at elevations above 800 m, mean coldest month temperature is 23°C, while in the hilly terrains at medium elevations (800 – 1,400 m) it varies between 16 and 23°C. Correlating with the sharp decrease in rainfall beyond the crest of the Ghats, the length of the dry season rapidly increases in the west-east direction. However, the monsoon onset in the south, which moves
northwards up to the Himalayas and then retreats in the reverse, creates a differential seasonal pattern with latitude, which does not correlate with rainfall. Consequently, the dry season length increases also from south to north.

B. Sampling design.

The study area was gridded into 801 by 401 0.01-DD/WGS84 cells (i.e. 30s' lat/lon or 1.11 km square), starting from the south-westernmost corner at 73.995 E and 7.995 N in Decimal Degrees (DD). It consequently covers a rectangle from approximately 74 to 78° E and 8 to 16° N. The study region was delineated from this matrix as a subset of cells bearing positive values for the vegetation variables, while the error code -9999 was attached to all cells outside the study region.

C. Research methods.

1. Laboratory/field methods.

• Simplified forest map of South India

For the purpose of a regional analysis, we created from a series of detailed forest maps of South India published by the French Institute of Pondicherry at 1:250.000 scale (Pascal et al. 1982a, 1982b, 1984, 1992; Ramesh et al. 1997, 2002), a simplified 1-km resolution vegetation cover map for the entire Western Ghats. Initially, the natural vegetation was classified along bioclimatic and disturbance gradients into more than 150 different types using the concept of climatic climax and dynamics of succession through criteria like phenology, physiognomy and floristic composition (Pascal 1986, Ramesh & Pascal 1996). From a complete georeferenced set of maps we regrouped these classes into 13 broader categories more suitable for a regional analysis. We first considered wet and dry zones formations separately, from a mean annual rainfall isoline of 2,000 mm, which is the general limit of the potential area of wet evergreen forests (Pascal 1984). In each zone, we then classified the vegetation based on retrogressive degradation stages ranging from dense primary forests to secondary or disturbed and degraded formations (scrub woodland to thickets). In the wet zone, these formations become progressively dominated by deciduous species, shrubby and scrubby undergrowths (sometimes as weeds). In the dry zone, we distinguished moist and dry deciduous as well as dry evergreen forests, primary and degraded stages together, keeping tree savannas and grasslands formations in a separate category. Finally, mountain forests and grasslands (> 1,800 m) were classified separately since they are present in both dry and wet
zones. We also kept highly human impacted areas, like plantations and agricultural lands, in separate categories. These simplified vegetation types are coded as indicated in Table 1 (see also Appendix A).

**Table 1.** Simplified vegetation types for the southern Western Ghats as defined from the FIP forest maps at 1:250,000 scale.

**MODIS IGBP Land Cover Types**

A second vegetation map was created from the 2004 MODIS Land Cover Type 1 (MODIS/Terra Land Cover Type Yearly L3 Global 1 km SIN Grid V004), referenced as MCD12Q1 and downloadable from the LP DAAC (Land Processes Distributed Active Archive Center) of the NASA ([http://lpdaac.usgs.gov/lpdaac/get_data](http://lpdaac.usgs.gov/lpdaac/get_data)). It identifies 17 land cover classes defined by the International Geosphere Biosphere Programme (IGBP), which includes 11 natural vegetation classes, 3 developed and mosaic land classes, and three non-vegetated land classes. These classes are coded as in Table 2 (see also Appendix B).

• *MODIS March 2004 NDVI map*

A map of the energy absorption of plant canopies during the dry season was created from MODIS Normalized Difference Vegetation Index (NDVI; Sellers 1985) of March 2004 (MODIS/Aqua Vegetation Indices Monthly L3 Global 1 km SIN Grid V005) referred as MYD13A3 and downloadable from the LP DAAC (Land Processes Distributed Active Archive Center) of the NASA ([http://lpdaac.usgs.gov/lpdac/get_data](http://lpdaac.usgs.gov/lpdac/get_data)). Values of NDVI*10,000 are given as real numbers between 0 and 10,000. A few pixels (43) that bore erroneous values above 60,000 have been assigned with the error code -9999 (Appendix C).

2. **Instrumentation.** All data layers have been worked out with ArcView GIS version 3.2a (ESRI Inc., Redlands, CA).

3. **Legal/organizational requirements.** The MODIS data are distributed at no cost to the user ([http://lpdaac.usgs.gov/lpdac/get_data](http://lpdaac.usgs.gov/lpdac/get_data)). The simplified vegetation data derived from the FIP forest maps of South India are also made freely available for non-commercial purpose.

**D. Project personnel.** Quentin Renard (International Volunteer), B. R. Ramesh (Expert Botanist), G. Muthusankar (Engineer in Geomatics) and Raphaël Pélissier (Head of Ecology)
Department) are all affiliated to the French Institute of Pondicherry. Authors of original forest maps of South-India were also affiliated to the FIP.

III. DATA SET STATUS AND ACCESSIBILITY.

A. Status.

1. Latest update. The data set was prepared during year 2009.

4. Data verification. The data were verified by careful examination and crosschecking of coloured level maps generated from the data using ArcView. These maps are given in an appendix to this document.

B. Accessibility.

1. Storage location and medium. Ecological data archives of the French Institute of Pondicherry (http://www.ifpindia.org/). Paper and digitized versions of the forest maps of South India (Pascal et al. 1982a,b, 1984, 1992; Ramesh et al. 1997, 2002) are stored at the Geomatics and Applied Informatics Laboratory (LIAG) of the French Institute of Pondicherry. They are also available as a webmapping application from the FIP Forest Biodiversity Portal (http://www.ifpindia.org/biodiversityportal/) and as scanned images with their explanatory notice from the HAL repository (http://hal.archives-ouvertes.fr/). Original MODIS Land Cover Type and NDVI data are stored at http://lpdaac.usgs.gov/lpdaac/get_data.

2. Contact person(s). Head of Ecology Department (ifpeco@ifpindia.org) and Head of Geomatics and Applied Informatics Laboratory, French Institute of Pondicherry, 11 St. Louis Street, 605001 Pondicherry, India, tel. +91 413 2334 168, fax +91 413 2339 534.

3. Copyright restrictions. None.

4. Proprietary restrictions. Due citations to University of Maryland (see http://www.landcover.org/data/) for MODIS products, to Pascal et al. (1982a,b, 1984) and
Ramesh et al. (1997, 2002) for the original FIP forest maps of South India, as well as to the present data paper should be included within any publication based on this dataset.

IV. DATA STRUCTURAL DESCRIPTORS.

A. Identity. Data are downloadable as a single zip archive (240 Ko) containing three data files:

1. IFP_ECODATA_VEGETATION_FIP_Map.txt. Contains 0.01-DD simplified vegetation classes derived from the FIP forest maps of South India.
2. IFP_ECODATA_VEGETATION_MODIS_LCT.txt. Contains 0.01-DD MODIS 2004 IGBP Land Cover Type classes.
3. IFP_ECODATA_VEGETATION_MODIS_NDVI.txt. Contains 0.01-DD MODIS NDVI values for March 2004.

B. Size. All data file contain the same number of rows (801) and columns (401) corresponding to 0.01-DD cells. No headers are included. Uncompressed file size are:

<table>
<thead>
<tr>
<th>Data File</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFP_ECODATA_VEGETATION_FIP_Map.txt</td>
<td>1.6 Mo</td>
</tr>
<tr>
<td>IFP_ECODATA_VEGETATION_MODIS_LCT.txt</td>
<td>1.6 Mo</td>
</tr>
<tr>
<td>IFP_ECODATA_VEGETATION_MODIS_NDVI.txt</td>
<td>1.8 Mo</td>
</tr>
</tbody>
</table>

C. Format type and storage mode. The data files are in ASCII text format, space delimited.

D. Header information. The data files do not contain any header, but the following lines can be added at the beginning of each text file (.txt) to transform them into ASCII files (.asc) readable by most GIS softwares:

```
Ncols 401
Nrows 801
Xllcorner 73.995
Yllcorner 7.995
Cellsize 0.01
NODATA_value  -9999
```

`ncols` and `nrows` give the number of columns and rows of the grid; `xllcorner` and `yllcorner` correspond to longitude and latitude of the south-westernmost corner of the grid in Decimal Degrees (DD/WGS84); `cellsize` is the size of the square cell of the grid (0.01 DD); `NODATA_value` is the code used for missing values.
E. **Special characters.** -9999 is the code used for missing values, also used to delineate the study region within the square matrices of 801 rows by 401 columns.

F. **Authentication procedures.** Sums of all numeric values (including the error code -9999) in each data file are given below:

<table>
<thead>
<tr>
<th>Data File</th>
<th>Sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFP_ECODATA_VEGETATION_FIP.txt</td>
<td>-2628592563</td>
</tr>
<tr>
<td>IFP_ECODATA_VEGETATION_LCT.txt</td>
<td>-2627026631</td>
</tr>
<tr>
<td>IFP_ECODATA_VEGETATION_NDVI.txt</td>
<td>-2309292916</td>
</tr>
</tbody>
</table>

V. **SUPPLEMENTAL DESCRIPTORS.**

A. **Data acquisition.** See the respective primary references: Pascal *et al.* (1982a,b, 1984, 1992) and Ramesh *et al.* (1997, 2002) for the FIP forest maps of South India; Strahler *et al.* (1999) and Huete *et al.* (1999) for MODIS land cover and NDVI data, respectively.

B. **Publications and results.** This dataset has been generated in the framework of a study on forest fire occurrences in the Western Ghats by Renard (2008).
