Abstract

Polybrominated diphenyl ether (PBDE) concentrations were measured in the blubber of five mother-pup pairs of grey seals (*Halichoerus grypus*) from Sable Island, Nova Scotia (NS) sampled in 1995 and in 20 British Columbia (BC) sampled in 1991-92. Concentrations in maternal grey seals from Sable Is. averaged 113 ± 55.2 ng/g lipid (mean $\pm$ s.d.) and were over twice the concentrations measured in their pups; lower brominated PBDEs showed a distinct decline in PBDEs transfer efficiency in mother-pup pairs as a function of increasing $K_{o/w}$. Hepta-BDEs and higher molecular weight (MW) congeners appear not to be transferred efficiently from the grey seals mother to pup during lactation on the basis of lipid/water partitioning (as indicated by $\ln K_{o/w}$) and this may be a consequence of molecular size (MW >600 Daltons) which may limit diffusion and partitioning. PBDE concentrations in blubber from harbour seals from the Strait of Georgia averaged 319 ± 132 ng/g lipid (mean $\pm$ s.d., $n = 13$), while those from the more remote and less contaminated Quatsino Sd. averaged 27.8 ± 11.8 ng/g (mean $\pm$ s.d., $n = 7$). Tri- to hexa- BDEs were appreciably enriched in Strait of Georgia harbour seals relative to those from Quatsino Sd, suggesting that the former were closer to PBDE sources. The main congeners identified in all samples were BDEs 47, 99, 100, 153 and 154. Data were compared to those in ringed seals sampled from Holman, North West Territories (NWT), in 1996. The Holman samples had a higher proportion of lower bromination congeners, and a lower proportion of higher bromination congeners, than did the Sable Island and BC seal samples, consistent with selection in favour of more volatile compounds during atmospheric transport to the Arctic.

1. Introduction

For approximately the last decade polybrominated diphenyl ethers have been identified as pollutants of growing concern. These chemicals have been used since the 1980's, and continue to be used though under increasingly restricted conditions (Hites, 2004; de Wit et al., 2006) mainly as flame retardants in fabrics and other materials. Like other organic pollutants, PBDEs accumulate in higher trophic level-feeding marine biota, and have been described in marine mammals from eastern and western Canada, and in populations far removed from local PBDE sources (Ikonomou et al., 2002; Rayne et al., 2004; Lebeuf et al., 2004; de Wit et al., 2006).

In this paper, we describe PBDE distribution in mother-pup pairs of grey seals (*Halichoerus grypus*) from Sable Island NS, sampled in 1995 and in two populations of harbour seals (*Phoca vitulina*) sampled from the BC coast in 1991-92; both populations were sampled previously to provide information on contamination by polychlorinated biphenyls (PCBs) and polychlorinated dibenzo-*p*-dioxins and furans, but no data have been published describing their PBDE contamination.

We compare the distribution of PBDEs with that of legacy POPs measured in these samples, and with PBDEs and other organic pollutants in other seal populations from various sites in Canada and elsewhere. Since the production and use of PBDEs changed rapidly between 1980 and 2000 (e.g., Ikonomou et al., 2002) our comparisons have focussed deliberately on samples taken only during the fairly narrow interval of 1991-92 (harbour seals) and 1995 (Sable Island grey seals). We have also compared these data to PBDE concentrations in Holman ringed seals sampled in 1996 and published elsewhere (Ikonomou et al., 2002). These comparisons allow us to assess the processes and factors which control the exposure of seals to these chemicals and their distribution in seals. The data sets

1 compared in this paper captures most of the Canadian seals PBDE data published so far, and
2 since all the samples were analyzed by the same laboratory following the same analytical
3 protocols the analytical data are internally consistent.

5 **2. Materials and Methods**

6 Blubber from five isolated mother-pup pairs of grey seals were sampled on Sable
7 Island in February 1995. Detailed sample information can be found in Addison et al. (1999).
8 (Mother-pup pair 149204 was omitted from PBDE analyses.) The samples had previously
9 been analysed for residues of polychlorinated biphenyls (PCBs) and for polychlorinated
10 dibenzo-dioxins and furans (PCDD/F) (Addison et al., 1999) and the archived extracts from
11 these analyses were re-analysed for PBDEs. Blubber was sampled from harbour seals in
12 1991-92 from the Strait of Georgia, and from Quatsino Sd., Vancouver Island. These animals
13 were shot as predators on fish farms, and so variables such as sex and age could not be
14 controlled. The blubber samples were analysed for PCBs and PCDD/F (Addison et al., 2005)
15 and 20 archived extracts from these analyses were re-analysed for PBDEs. Figure 1 shows
16 the location of the sampling sites, and of Holman, NWT. The archived extracts for both the
17 Sable Island and the west coast samples (Strait of Georgia, and Quatsino Sd) were stored in
18 amber vials in the dark at -20°C.

19 As noted above, both the grey seal and the harbour seal samples were analyzed for
20 PCBs and PCDD/Fs as part of other studies. The sample extraction and clean-up procedures
21 used to process the samples for PCBs and PCDD/Fs have been described in detail elsewhere
22 (Ikonomou et al., 2001). Four fractions were collected from each of the samples and those
23 were analyzed for target PCBs and PCDD/Fs by high-resolution gas chromatography high-
24 resolution mass spectrometry (HRGC-HRMS). Following these analyses the four fractions

1 were combined, spiked with a suite of ^{13}C -labeled PBDE standards (method internal and
2 performance) and analyzed for mono- to hepta-BDEs by HRGC-HRMS. The extracts from
3 the Sable Island samples were analyzed for octa- to deca-BDEs as well but the concentrations
4 measured were close to the levels measured in the procedural blanks and thus not reported.
5 The composition of the ^{13}C -labelled PBDE standards used for quantification, the instrumental
6 analysis conditions used, the quantification protocols, the criteria used for congener
7 identification, and the quality assurance/quality control (QA/QC) measures undertaken for
8 the HRGC-HRMS analysis of PBDE target analytes are described in detail elsewhere
9 (Ikonomou et al. 2001 and 2002). Since the samples were not spiked at the extraction step
10 with labelled PBDE internal standards, percent recoveries of the PBDE method internal
11 standards were unknown. However, extensive method validation experiments with this matrix
12 have enabled us to confirm that the extraction efficiency of the PCBs and PBDEs are similar
13 under the experimental conditions used. Therefore, we used percent recoveries of the labelled
14 PCB internal standards, obtained from the corresponding analyses described above, to
15 establish the percent recoveries of the labelled PBDEs internal standards and to quantify the
16 native PBDE concentrations accordingly. The mono- to hepta-BDE levels measured in the
17 procedural blanks associated with the analysis of these samples totalled 3500 pg/g and were
18 accounted for mainly by BDE 138/166 (2000 pg/g) and BDE 140 (1000 pg/g). Detection
19 limits for the Sable Is. grey seal analyses were in the range 1.6 pg/g (mono- and hepta-BDEs)
20 to 13.7 pg/g (penta-BDEs) and for the BC harbour seal analyses were in the range 0.6 pg/g
21 (mono- and penta-BDEs) to 21.5 pg/g (hexa-BDEs). The concentrations of the mono- to
22 hepta-BDE congeners measured in all the samples were orders of magnitude higher than
23 those measured in the blanks and the data were not blank corrected.

To provide information about the importance of atmospheric transport in controlling the distribution of PBDEs in seal populations, data from these analyses were compared in detail with data from ringed seals (*Phoca hispida*) from Holman, NWT, sampled in 1996 details of which can be found in Ikonomou et al., 2002. Data were analysed using software from Statistica (Statsoft, OK).

3. Results

3.1. PBDE residues in Sable Island grey seals.

The PBDE concentrations of the all the congener groups for the five mother-pup pairs examined in this study are summarized in Table 1. Total PBDEs were distributed normally (Kolmogorov-Smirnov test) in both mothers and pups. Total PBDE concentrations were around 110 ng/g wet weight in maternal blubber, and about 46 ng/g wet weight in pups. No mono-BDEs were detected, and only BDE 15 was detected among the di-BDEs. The main tri-BDE was the pair BDE 28/33 which accounted for about 80% of this group. BDE 47 comprised over 90% of the tetra-BDEs, and BDE 99 and BDE 100 represented (respectively) about 50% and 40% of the penta-BDEs. Similarly, BDE 153 and 154 represented about 50% and 40% respectively of the hexa-BDEs. Tetra-, penta-, and hexa-BDEs represented (respectively) about 62%, 18% and 18% of total BDEs in mothers; because of differences in the "transfer efficiency" of these compounds from mother to pup via milk, discussed in detail below, these three congener groups in the pup represented about 79%, 14% and 5% of the total. Only traces of hepta- and higher PBDEs were found in either mother or pup. Figure 2 summarises the major individual BDE congener concentrations in mothers and pups.

Total PBDE concentrations in adult female grey seals showed no statistically significant variation with age, but sample size was small (n=5).

The transfer of PBDE from mother to pup during lactation declined consistently with increasing Br substitution from di- to hexa-BDE, and then levelled off (Table 1). However, variance in the concentrations of higher BDE groups (above hexa-BDE) was high (s.d. usually about equal to the mean, whereas in di- to hexa-BDEs, s.d. was about 60% of the mean) perhaps due partly to the fact that concentrations were approaching the detection limit. This increasing variance in higher BDE congener groups may have skewed the relationship with increasing bromination. Figure 3 shows a plot of mean % transfer of di- to hepta-BDE from mother to pup versus $\ln K_{ow}$ (calculated from data of Braekevelt et al., 2003).

3. 2. PBDE residues in British Columbia harbour seals.

The total PBDE concentrations of the major PBDE congener groups measured in two populations of harbour seals are summarized in Table 2. Again, total PBDEs were distributed normally in both Strait of Georgia and Quatsino Sd. sample sets. PBDE concentrations differed widely in the blubber of harbour seals from these two populations, with tetra- and penta-BDEs in samples from the Strait of Georgia being more than an order of magnitude higher than those in Quatsino Sd. samples. Differences in tri-, hexa- and hepta-BDEs, although large, are more probably related to general "background" contamination. As noted previously (Addison et al., 2005) the Strait of Georgia samples had about half the blubber thickness of the Quatsino Sd. samples, so the PBDE burden (as opposed to concentration) of the former would probably be only about five times as great as in the latter. There was little difference between the sexes in total PBDE concentrations at either site: in Strait of Georgia samples, females contained 306 ± 99 ng/g lipid (mean $\pm$ s.d., n=9) and males 348 ± 205 ng/g

lipid (n=4) in Quatsino Sd., females contained 26 ± 19 ng/g lipid (n=3) and males 29 ± 6 ng/g lipid (n=4). Sample sizes were too small, and the range of ages covered too large, for the possible effect of age on sex differences to be detected. The distribution of the six major congeners in the two sample sets are presented in Fig. 4; BDE 47 (representing >98% of tetra-BDEs), BDE 99 and 100 (65-75% and 23-33% of penta-BDEs), BDE 153 and 154 (63-86% and 9-23% of hexa-BDEs) and BDE 183 (>90% of hepta-BDEs) predominated. Table 2 also shows that there was a considerable enrichment of tetra- and penta-BDEs, and possibly of tri- and hexa-BDEs, in the Strait of Georgia samples.

In Strait of Georgia female harbour seals (n=9) there was no statistically significant variation with age. Sample sizes of male seals in the two BC harbour seal populations were too small (n=4) to undertake regression analyses.

4. Discussion

Of the three populations sampled, the harbour seals from the Strait of Georgia had the highest total blubber PBDE concentrations (> 300 ng/g lipid). These total concentrations are in the same range as those reported in harbour seals from the San Francisco area in 1989 and 1993 (She et al, 2002) but slightly lower than those found in North Sea harbour seals (Boon et al., 2002), and generally lower than killer whales and porpoise from the same general area (Ikonomou et al., 2002; Rayne et al., 2004). Sable Island grey seals had appreciably lower total PBDE concentrations (>100 ng/g lipid in adult females); these concentrations are similar to those reported for female northern fur seals collected in the mid-1990's from northern Japan (Kajiwara et al., 2004) but slightly lower than those reported for European gray seals in the early to mid-1990's (Law et al., 2003). Harbour seals from Quatsino Sd. had the lowest total PBDE concentrations (< 30 ng/g lipid); these concentrations are below most of those

1 reported in any marine mammals from northern hemisphere mid-latitudes, but more than an
 2 order of magnitude higher than concentrations in western Arctic ringed seals sampled in the
 3 mid-1990's (Ikonomou et al, 2002). The distribution of the major PBDE congeners, with
 4 BDE 47 predominant followed by BDEs 99 and 100 (Fig. 1) is similar to that reported for
 5 other north American marine mammals and probably reflects (mainly) the use of the "penta"
 6 PBDE mixture in North America.

7 The distribution of POPs (exemplified by PCBs and the DDT group) in seals is
 8 controlled by external factors such as exposure (usually through diet) and endogenous factors
 9 such as the age, sex and condition of the animals (Addison, 1989). In the case of the Sable
 10 Island grey seal pups, for practical purposes the only exposure route is ingestion of maternal
 11 milk. There may be some deposition of residues during foetal development, but this is very
 12 small in comparison to exposure through lactation. "Transfer efficiency" of PBDEs from
 13 mother to pup via lactation showed a clear decline with increasing K_{ow} (Fig. 3) but the
 14 relationship failed beyond the hexa-BDEs, as noted above. Braekevelt et al. (2003) have
 15 noted that the generally linear relationship between Br substitution and $\ln K_{ow}$ also tends to
 16 become asymptotic beyond hepta-BDEs. The factors which govern the transfer from mother
 17 to pup of hepta-BDEs and higher are not clear: it may be significant that hexa- and hepta-
 18 BDEs have MW of 698 and 786 Daltons, respectively, and there is evidence the transport of
 19 lipophilic compounds of MW above about 600 Daltons across biological membranes may be
 20 difficult (e.g., Niimi and Oliver, 1988). The process of transfer may be further complicated
 21 by the fact that some re-synthesis of lipid in mammary tissue may take place (Iverson et al,
 22 1995). The transfer of PBDEs, particularly the higher congeners, from mother to pup via
 23 milk is therefore not simply a process of diffusion and partition.. A similar reduction in
 24 transfer from mother to pup in higher congener groups was also observed with mono-ortho-

PCBs and (Addison et al., 1999) and was attributed to increasing octanol-water partition coefficient (K_{ow}) with increasing Cl substitution (or increasing MW or molecular size, all of which co-vary); this implied increase in lipid solubility with increasing Cl substitution would probably reduce partitioning into blood, which is the first step in transfer of POPs residues from blubber into milk. Similar factors appear to govern the transfer of at least the lower PBDE congener groups from mother to pup.

Total PBDE transfer from mother to pup was $44.4 \pm 9.9\%$ ($n=5$). This is fairly similar to the transfer of PCBs which were estimated to be in the 30-40% range but probably less than DDT-group transfer (40-60%: Addison and Brodie, 1977; 1987).

In adult seals, the main route of exposure to POPs must be through diet, whose contamination in turn depends on various inputs which would include at a minimum local (perhaps "point source") discharges, and/or long range atmospheric or advective transport. Comparison of the PBDE congener distribution patterns in the seal population discussed here, and with others, allows us to infer something about the relative importance of these sources. Consider first the BC harbour seals: the Strait of Georgia represents the "receiving waters" for industrial and municipal discharges from the greater Vancouver and SE Vancouver Island area (approximate population 3M). Quatsino Sd. is a relatively remote inlet in western Vancouver Island, receiving wastes only from the small community of Port Alice and a local pulp mill. In previous analyses (Addison et al. 2005) it was shown that the polychlorinated dibenzo- dioxin and furan (PCDD/F) distribution in these samples reflected both the expected qualitative and quantitative differences in discharges of industrial wastes in these two areas. Thus, total PCDD and PCDF burdens in the Strait of Georgia samples were estimated to be (respectively) about 8-fold and 3-fold higher than in Quatsino Sd.; furthermore, enrichment of 1,2,3,6,7,8-hexachlorodibenzo-*p*-dioxin and 2,3,7,8-tetrachlorodibenzofuran (both of

1 which were characteristic of bleached kraft mill discharges during the 1990's) in the Strait of
2 Georgia samples identified such effluents as a significant source of these chemicals. In other
3 words, the PCDD/F data show that these two seal populations reliably reflect quantitative and
4 qualitative differences in local contaminant sources. The relative distribution of PBDEs in
5 the two harbour seal populations follows the pattern of PCDD/F; i.e., total PBDE
6 concentrations were about 11-fold higher in the Strait of Georgia samples than in Quatsino
7 Sd., corresponding to a difference in residue burdens (because of differences in condition of
8 the two samples: see Addison et al, 2005 for a discussion) of about 5-fold. Furthermore, the
9 relative enrichment of tri- to hepta-BDEs in the Strait of Georgia suggests that these samples
10 may have been closer to the putative source of PBDEs in the Strait of Georgia. However,
11 when congener group distribution is expressed as a percentage of total PBDEs, there is little
12 evidence in favour of the skewing of PBDEs in Quatsino Sd. samples in favour of lower MW
13 (and hence more volatile) components (Fig. 4). This suggests that atmospheric transport may
14 not be a significant route of transport of PBDEs into Quatsino Sd.

15 Sable Island is considered relatively remote and free from local sources of
16 contamination; nevertheless, it is both downstream and downwind from the St. Lawrence
17 basin which represents a large urbanised and industrialised area. Bidleman et al., (1992)
18 have documented atmospheric transport of contaminants into Sable Island via the prevailing
19 westerly winds, and either atmospheric or water advective transport (or both) probably
20 contributed to contamination of the gray seal population by DDT and its degradation products
21 (Addison and Stobo, 2001). Mean total PBDE concentrations were lower than in the Strait of
22 Georgia harbour seals, which would be expected given Sable Island's relative remoteness;
23 however a potentially confounding factor is the fact that grey seals and harbour seals may
24 feed at slightly different trophic levels, or may differ in their capacity for metabolic

1 degradation of compounds such as PBDEs. The relative distribution of the main PBDE
2 congener groups (Fig. 5) did not differ appreciably between the Sable Island grey seals and
3 the BC harbour seals, which suggests that "sorting" of PBDE congeners on the basis of their
4 vapour pressure or other physico-chemical properties is relatively unimportant.

5 In contrast, comparison of the Sable Island grey seal data and the BC harbour seal
6 data with data from western Arctic ringed seals illustrates the probable importance of
7 atmospheric transport in introducing PBDEs to the Arctic. Figure 5 shows the main congener
8 group distribution in ringed seals compared to those in the Sable Island and BC seals: it is
9 clear that lower brominated PBDEs represent a higher fraction of total PBDEs, and higher
10 brominated groups a lower fraction, in the Arctic ringed seals. This suggests that there has
11 probably been some "sorting" of the supply of PBDEs to the western Arctic which is based
12 on congener volatility; this is not seen over the shorter distribution routes to Quatsino Sd. or
13 to Sable Island.

14 Finally, the role of metabolic degradation and the significance of trophic level are
15 factors which must be considered in making inter-species comparisons, as we have done here.
16 At first sight, grey seals may appear to function at a higher trophic level than the other two
17 species, as they face no direct predators, unlike the harbour and ringed seals which are preyed
18 on by (respectively) killer whales and polar bears. In practice, however, all three seal species
19 are, to a varying extent, fairly opportunistic feeders, and feed on small- to medium-sized fish
20 and large invertebrates (e.g., Smith, 1987; Addison and Stobo, 2001;) and have been
21 assigned to similar trophic levels based on dietary analyses (Pauly et al., 1998). In this sense,
22 our inter-species comparisons are justified. The role of metabolic degradation in controlling
23 PBDE congener distribution is more difficult to assess. Experimental studies on BDE
24 congener metabolism by aquatic species has been limited to studies on fish, from which it has

1 been inferred from comparative congener distribution and from the occurrence of
2 hydroxylated and methoxylated metabolites that some degradative capacity exists (e.g.,
3 Stapleton et al., 2004a, b; Isosaari et al. 2005) though it is recognised that some of the
4 methoxy-derivatives may have a natural source (e.g., Marsh et al., 2005). Observational
5 studies on natural marine food chains (Wolkers et al., 2004) have also suggested that some
6 degradative capacity for some BDE congeners may exist in ringed seals, and components of a
7 cytochrome P-450 system (which could contribute to BDE degradation) exist in both grey
8 and harbour seals (Addison and Brodie, 1984; Addison et al, 1986). However, the
9 significance of possible differences in degradative capacity among the species discussed here
10 is impossible to assess.

1 Table 1: Major PBDE congeners and congener groups (pg/g lipid) in blubber of mother and
 2 pup grey seals (*Halichoerus grypus*) and calculated transfer (pup conc. as % maternal conc.)
 3 from Sable Island, NS, in 1995. Data quoted to 3 significant figures as mean $\pm$ s.d. (n=5
 4 unless otherwise stated) or as range (pup maturity). ND, not determined.

Group:	Mothers	Pups	Pup blubber conc. as % maternal blubber conc.
PBDE congener or group			
Age (y)	13.8 $\pm$ 3.70	Stage III-V	
Blubber thickness (cm)	2.66 $\pm$ 0.300	4.82 $\pm$ 0.680	
Total mono-BDE	ND	ND	
Total di-BDE	15.3 $\pm$ 9.76	14.1 $\pm$ 7.48	100 $\pm$ 25.1
BDE 17	119 $\pm$ 65.6	114 $\pm$ 74.5	
BDE 28/33	634 $\pm$ 383	437 $\pm$ 276	
Total tri-BDE	877 $\pm$ 623	555 $\pm$ 336	66.1 $\pm$ 17.4
BDE 47	69700 $\pm$ 30400	39500 $\pm$ 21100	
BDE 66	177 $\pm$ 100	51.8 $\pm$ 16.9 (n=4)	
BDE 75	40.3 $\pm$ 1.21 (n=3)	11.1, 5.30 (n=2)	
Total tetra-BDE	70200 $\pm$ 30800	39600 $\pm$ 21100	55.1 $\pm$ 11.9
BDE 99	10700 $\pm$ 7250	3920 $\pm$ 2520	

BDE 100	8730 ± 3920	2710 ± 1390	
Total penta-BDE	20800 ± 11200	7060 ± 4000	33.4 ± 8.53
BDE 153	9430 ± 6420	1200 ± 700	
BDE 154	8350 ± 5600	1250 ± 940	
BDE 155	2010 ± 1470	290 ± 195	
Total hexa-BDE	20000 ± 13100	2800 ± 1820	13.8 ± 3.65
Unidentified hepta-	527 ± 480	32.0 ± 14.1	
BDE II			
Total hepta-BDE	539 ± 492	33.8 ± 17.3	13.2 ± 15.6
Total di- to hepta-	112000 ± 55200	50000 ± 26800	
PBDE			

Table 2: PBDE congener and congener group concentrations (pg/g lipid) in harbour seals (*Phoca vitulina*) from Strait of Georgia (SoG) and Quatsino Sd. (QS), British Columbia in 1991-92. Sexes have been combined at each site. Data are quoted to 3 significant figures and presented as mean $\pm$ s.d. (no of samples). *P* is probability (by *t*-test) of spatial differences arising by chance. SoG/QS is ratio of mean concentrations at the two sites.

BDE group	Harbour seal, SoG	Harbour seal, QS	<i>P</i>	SoG/QS
Sampling period:	1991-92	1991-92		
No. of samples taken:	9F, 4M	3F, 4M		
Age (y)	4.90 $\pm$ 5.10 (13)	8.40 $\pm$ 4.90 (7)		
Blubber thickness (mm)	18.5 $\pm$ 6.1 (13)	38.1 $\pm$ 13.0 (7)		
total di-BDE	26.0 $\pm$ 10.8 (8)	20.5 $\pm$ 18.1 (6)	NS	1.3
BDE 17	325 $\pm$ 132 (12)	53.7 $\pm$ 31.8 (7)		
BDE 28/33	1420 $\pm$ 486 (12)	350 $\pm$ 148 (7)		
total tri-BDE	1,770 $\pm$ 529 (12)	417 $\pm$ 184 (5)	<0.01	4.2
BDE 47	225,000 $\pm$ 94,300 (13)	18,700 $\pm$ 7730 (7)		
BDE 66	568 $\pm$ 280 (12)	127 $\pm$ 58.4 (7)		
BDE 75	60.4 $\pm$ 38.5 (4)	60.2 $\pm$ 29.4 (5)		
total tetra-BDE	229,000 $\pm$ 98,000 (13)	19,000 $\pm$ 7,790 (7)	<0.001	12.0
BDE 99	53,800 $\pm$ 27,100 (13)	3,540 $\pm$ 1,970 (7)		
BDE 100	16,600 $\pm$ 6,300 (13)	1,840 $\pm$ 844 (7)		
total penta-BDE	70,400 $\pm$ 31,800 (13)	5,410 $\pm$ 2,680 (7)	<0.001	13.0

BDE 153	14,900 ± 6460 (13)	1,830 ± 1,310 (7)		
BDE 154	1,600 ± 620 (13)	692 ± 603 (7)		
BDE 155	713 ± 323 (13)	383 ± 307 (7)		
total hexa-BDE	17,300 ± 7,170 (13)	2,920 ± 1970 (7)	<0.001	6.0
BDE 183	143 ± 56.7	85.7 ± 49.6		
total hepta-BDE	154 ± 66.4 (13)	87.7 ± 51.6 (7)	<0.001	1.8
Total tri- to hepta PBDE	319,000 ± 132,000 (13)	27,800 ± 11,800 (7)	<0.001	

1 Captions for Figures.

2 Figure 1. Map of Canada showing seal sampling sites discussed in the study. QS,
3 Quatsino Sd., BC; SoG, Strait of Georgia, BC.

4

5 Figure 2. Concentrations of major brominated diphenyl ether (BDE) congeners in
6 mother and pup grey seals (*Halichoerus grypus*) from Sable Island, NS in 1995. Note
7 that BDE concentrations (y axis) are on a log scale to illustrate mother pup differences
8 in congeners present at concentrations over 4 orders of magnitude.

9

10 Figure 3. Mean transfer of major brominated diphenyl ether (BDE) congeners from
11 mother to pup via milk in five Sable Island grey seals (*Halichoerus grypus*) mother-
12 pup pairs as a function of $\ln K_{o/w}$. For di- to hexa-BDE, regression has the form:

$$13 \quad \% \text{ transfer} = (-32.9 \pm 2.89) \ln K_{o/w} + 271; r = 0.98, n = 5, P < 0.01$$

14

15 Figure 4. Concentrations of major brominated diphenyl ether (BDE) congeners in
16 harbour seals (*Phoca vitulina*) from the Strait of Georgia and Quatsino Sd., BC in
17 1991-92. Note that BDE concentrations (y axis) are on a log scale to illustrate
18 geographic differences in congeners present at concentrations over 4 orders of
19 magnitude.

20
