Abstract:

Vasculitis is a disorder characterized by inflammation of blood vessels. Its clinical manifestations are diverse and depend on the size of the involved vessels and the organs affected by ischemia. In some cases the disease is manifested only with symptoms and signs of systemic inflammation (e.g., fever, night sweats, fatigue,). Results of laboratory tests usually indicate only the inflammatory process. It is known that radiolabeled glucose analogue 18F- fluoro-deoxyglucose ([18F] FDG) used in positron emission tomography (PET) accumulates in both malignant and inflammatory tissue (1). We report a case of a patient with FDG-PET/CT findings of large vessel vasculitis with follow-up results that convinced us to change the treatment.

Key words: vasculitis, PET, fluoro-deoxyglucose, diagnosis, follow-up

Case

69-year-old Caucasian woman was admitted to local hospital because of fatigue, sweating, anorexia, recurrent fever at 38-39 °C, 4kg weight loss in one month. There were no symptoms of specific organ damage and the physical examination was without abnormalities. Laboratory studies showed elevated ESR 100/ hour, C-reactive protein 192mg/l and hypochromic anaemia with haemoglobin 97g/l. Hepatic transaminase activity was slightly elevated, kidney function tests were normal. Infectious aetiology was not the probable cause of inflammation (no bacterial growth in urine and haemocultures, negative serological tests and PPD skin test). Thoracic radiography was without inflammatory changes. Abdominal and pelvic ultrasound imaging were unremarkable. Autoantibodies ANA, ASMA, AMA were negative. The thoracoabdominal CT scan was performed and has shown the thickening of aorta wall 3-4mm, both of superior mesenteric artery and left renal artery without stenosis.

The patient was admitted with these findings to our department. Because of suspicion of autoimmune vasculitis PET/CT scan was performed. The images were remarkable for extensive abnormal [18F]FDG accumulation along the walls of the thoracic and abdominal aorta, subclavian and axillary arteries, common carotid arteries, superior mesenteric arteries, iliac arteries and upper parts of femoral arteries (Fig.1).

We initiated treatment with a high dose methylprednisolone pulse therapy with a dose 500mg/day and continued with 60mg/day of oral prednisone with good clinical and laboratory effect (no fever, decreasing of CRP). Because of large vessel changes treatment with cyclofosamid 50mg/day was started as well.

Six months after the introduction of therapy (therapy at this time prednisone 20mg, cyclophosphamid 50mg/day) the only symptom of the patient was night sweats, the blood count was normalized, but CRP (45.90 mg/l) and ESR (38/70) were elevated. Follow-up PET/CT scan was performed. Abnormal [18F]FDG uptake was demonstrated in thoracic aorta, subclavian and axillary arteries but of a much lower intensity as on the baseline scan (Fig.2). Combination of cyclophosphamid with cyclosporine A 100mg/day was administered, glucocorticoid treatment was continued. This therapy led to normalization of ESR and CRP with sustained remission after 2 months.

Discussion

This case illustrates an atypical clinical presentation of large- vessel vasculitis with no clinical symptoms of organ damage and without the possibility of verification of suspected diagnosis with biopsy. The only patient's symptoms were signs of

systemic inflammation which are common in fever of unknown origin (FUO). The large-vessel vasculitis is considered to be the cause in 17% of all FUO patients (2).

FDG-PET is a non-invasive diagnostic method which shows the bio-distribution of positron emitter labelled radiopharmaceuticals in the body. Fluoro-deoxyglucose is accumulated in tumour cells but also in inflammatory tissue due to the over-expression of glucose –transporter (GLUT, mainly GLUT 1,3) and overproduction of glycolytic enzymes (3). FDG-PET is highly effective in detecting large vessel vasculitis anywhere in the body and has high sensitivity (77-100%) and specificity (89-100) (3). The percentage of PET scans helpful in the diagnostic process in patients with FUO varied from 41 to 69% (4). Combination of CT and PET images has an advantage of direct correlation of pathological changes in metabolic activity with precise anatomical localization in one fusion image. The residual FDG uptake on follow-up PET/CT examination in our case correlated with laboratory and clinical activity of the disease and indicated a more intensive anti-inflammatory treatment was needed.

Conclusion

[18F]FDG-PET/CT is an effective combination of imaging modalities in assessing the activity and extent of large vessel vasculitis with high sensitivity and specificity. This investigation has also been used to follow up patients over time and to monitor response to anti-inflammatory and immunosuppressive treatment.
