Abstract

The human population is exposed to dioxins (PCDD/Fs) and dioxin-like polychlorinated biphenyls (dl-PCBs) mainly through diet; bioaccumulation and biomagnification in aquatic environment results in fishery products and by-products being an important vector to humans. The determination of PCDD/Fs and dl-PCBs in fillets of young turbot (*Psetta maxima*) (0 – 2 years) from aquaculture plant (Galicia, Spain) (N = 21) and in feedingstuffs were carried out, and dietary accumulation values and lipid-normalized biomagnification factors (BMF) relating concentration in fish and in feed were calculated. Levels found in feedingstuffs (0.5 pg TEQ-PCDD/F / g and 1.6 pg TEQ-dl-PCB / g), and turbot (0.13 - 0.27 pg TEQ-PCDD/F / g fresh weight and 0.35 - 1.2 pg TEQ-dl-PCB / g fresh weight) were below maximum permitted levels set by EC. Levels of toxic compounds in feeding stuff are reflected in fish fillets; predominant isomers are 2,3,7,8-TCDF, OCDD, 1,2,3,7,8-PeCDF, 2,3,4,7,8-PeCDF and 1,2,3,4,6,7,8-HpCDD, and PCBs 118, 105, 156 and 167. Relevant compounds accounting for total toxicity are the same congeners in feeding stuff and turbot: 2,3,4,7,8- PeCDF; 2,3,7,8-TCDF; 2,3,7,8-TCDD and 1,2,3,7,8-PeCDD, and PCB 126. Higher accumulation efficiency values were obtained for dl-PCBs (30 - 46%); tetra- and penta-chloro substituted PCDD/Fs showed the highest values (27 - 34%) of the PCDD/F group. Biomagnification was shown for these compounds (BMF around 1.5).

Introduction

Turbot aquaculture is a very important activity in Spain, producing fish of remarkable quality due to optimal conditions of sea water of the northwest of the country. According to the United Nations Food and Agriculture Organization (FAO), by the year 2030 more than half of marine products for human consumption will come from aquaculture. Aquaculture is the only way to keep sea products in the daily diet in view of the stagnation of extractive fishing. In this sector, Galicia, in the northwest of Spain, is a world leader thanks to its natural conditions, especially its “rias”, and the commitment undertaken by Galicia’s companies and Administration. In the year 2002, Galician aquaculture attained an estimated production of more than 267,000 tons, dominating the Spanish market as one of the main suppliers of European markets (Anonymous, 2004). Galician aquaculture experienced continuous growth, in both the volume of its production and first-sale value, between 1994 and 2002, increasing from a value of 93.65 million euros to a total of 193.79 million, turbot representing 14.8% of this economical value (Anonymous, 2004). Many technical advances have been made in breeding turbot in Galicia, the European region where turbot growing is completed in the least time, thanks to the richness and temperature of its waters; at present, there are 17 farms in Galicia, including the largest in the world, in Lira, Carnota (A Coruña).

Feeding stuffs used in cultured fish are made mainly from fish oil and fish meal, being fish fat one of the main components where persistent contaminants such as dioxins and PCBs are accumulated, due to bioaccumulation and biomagnification in the aquatic environment. Due to aerial deposition and diffuse contamination of soil, these contaminants are found in roughages and other types of animal feed of vegetable origin. Contaminated surface waters, sediments and prey lead to dioxins and dl-PCBs in fish, and thus to contamination of fish meal and fish oils used as animal feed. Fishery products and by-products might constitute an important vector of dioxins in humans.

Due to the high toxicity of these compounds, particularly chlorinated dioxins and furans (PCDD/Fs) and dioxin-like PCBs (dl-PCBs), it has been necessary to establish the maximum permitted level (MPL): Directive 2002/32/EC establishes the maximum dioxins and furans content in feeding stuffs, and Regulation (EC) No. 2375/2001 in food. Recently established MPLs for the sum of dioxins/furans and dioxin-like PCBs

1
2
3 have been included in Directive 2006/13/EC (feeding stuffs) and Commission
4 Regulation No. 199/2006 (food).
5
6
7
8
9

10 In order to evaluate the safety of this aquaculture product and the relevance of the
11 feeding stuffs in the final levels of contaminants found in fish, determinations of
12 PCDD/Fs and dl-PCBs in turbot and in feeding stuffs have been carried out in this
13 study.
14
15
16

17 **Materials and methods**

18 *Sampling*

19
20
21
22 Two different feedingstuffs were used to feed the turbot: 8 mm diameter (fish younger
23 than 1 year), and 15 mm diameter (fish older than 1 year). Both feedingstuffs showed
24 similar proximal composition: about 20% fat, 53% protein, and 8% moisture. Both
25 feedingstuffs contained a proportion of marine fish oil (data not supplied).
26
27
28
29
30
31
32

33 Fish of three different age/size groups (from 0 to 2 years old) of turbot (N=21) (Table
34 1) were pooled from aquaculture plant in March 2005. Fish were frozen until analysis.
35
36
37

38 Determinations of PCDD/Fs and dl-PCBs in fish individual samples (N=21) and in
39 feedingstuffs used with them were carried out; analyses were performed in April 2005 -
40 June 2005. Fat content was determined by Soxhlet extraction procedure (AOAC 1990).
41 Dietary accumulation efficiencies were calculated using the equation $\alpha = C_{\text{fish}} / (F \times t \times C_{\text{feed}})$,
42 where C_{fish} is concentration in fish, C_{feed} is concentration in feed, F is feeding
43 rate and t is time, for each toxic congener in the turbot of 1-2 years old under study.
44 Feed conversion ratio (Kg food consumed / kg weight gain) of 1.1 was applied to
45 calculate the consumed quantity by each individual. This value is applied under
46 conventional turbot aquaculture conditions in the region, and represents the total
47 consumption by a total mass of fish.
48
49
50
51
52
53
54
55

56 *Sample pre-treatment*

57
58 Frozen fish were allowed to thaw (a few hours) and edible parts (fillets) were divided
59 into small pieces and homogenized with a food processor. Fish samples were previously
60

1
2
3 dried for 24 h using sodium sulphate. Feeding stuffs were grinded and directly
4 processed. Sub-samples of 20 g were taken for analysis.
5
6

7
8 For sample preparation and purification, open adsorption chromatography columns and
9 Supelco Dioxin Prep System were used, including empty tubes for multi-layer silica gel
10 columns, vacuum manifold, and accessory glassware and connectors. Preparation for
11 PCDD/Fs analysis was carried out as described by Sobrado *et al.* (2004). Sub-samples
12 obtained as described above were previously homogenized, next, they were spiked with
13 known amounts of mixtures of $^{13}\text{C}_{12}$ -PCDD/Fs and $^{13}\text{C}_{12}$ -dioxin-like PCBs (EPA-
14 1613LCS and WP-LCS WHO/EPA from Wellington Laboratories) and extracted using
15 adsorption chromatography with n-hexane:acetone (1:1). The extracts were rotary
16 evaporated and transferred to 5 mL n-hexane. In order to remove organic components,
17 fat and other interfering substances, the n-hexane extracts were passed through
18 chromatographic columns packed with silica and acid silica, modified with sulphuric
19 acid, using n-hexane as eluent. After solvent evaporation to 5 mL, the extract is cleaned-
20 up in a multilayer column, packed with silica, acid silica modified with sulphuric acid
21 and basic silica modified with potassium hydroxide, eluted with n-hexane, rotary
22 evaporated to 1 mL, and solid phase-extracted using carbon cartridge Supelclean-
23 Envicarb, from Supelco. Dioxins and furans are retained in carbon structure while
24 interferences are eluted by a direct flow of n-hexane:toluene (99:1 and 75:25
25 alternatively) and then eluted by reversed flow of toluene. Extract is evaporated to
26 dryness and re-dissolved in 5 μL of nonane and 5 μL of labelled internal standard
27 solution EPA-1613ISS (Wellington Laboratories), prior to injection.

39
40
41
42
43

44 Preparation for dl-PCBs analysis was carried out using adsorption chromatography,
45 following a similar procedure, but introducing the use of Supelco Prep System, by one
46 step method as described by Maeoka *et al.* (2002). This one-step method consists of a
47 multi-layer silica gel column, as described above for dioxins and furans, directly
48 coupled to a dual layer carbon column composed of two different carbon layers in series
49 with distinct binding characteristics, Carboxen 1016 and Carboxen 1000, from Supelco,
50 that retains dioxins and co-planar PCBs which are eluted by reversed flow of toluene.
51 Extract is evaporated to dryness and re-dissolved in 38 μL of nonane and 2 μL of
52 labelled internal standard solution WP-ISS WHO/EPA (Wellington Laboratories), prior
53 to injection.
54
55
56
57
58
59
60

1
2
3 Solvent concentration was carried out in a Laborota 4000 Heidolph connected to a
4 Büchi V-500 vacuum pump. Solvent evaporation was carried out under nitrogen in a
5 Reacti-Vap evaporator 18780 coupled to a Reacti-Therm heating module 18790, Pierce.
6 Organic solvents were for residue analysis; sodium sulphate granular was 99+% A.C.S.
7 reagent (Aldrich); silica gel 60 (0.063-0.200 mm) was for column chromatography
8 (Merck).
9

10 11 12 13 14 15 *Determination of PCDD/Fs and dl-PCBs*

16
17
18 PCDD/Fs and dl-PCBs were determined using high resolution gas chromatography
19 coupled to an ion trap tandem mass spectrometer (HRGC-MS/MS). Gas chromatograph
20 Varian CP-3800, equipped with an autosampler Varian CP-8400, a VF-5ms capillary
21 column (Factor Four, 60m x 0.25 mm ID, DF = 0.25, Varian); for PCDD/Fs separation,
22 1 μ L of sample is injected in splitless mode at 300° C, followed by column temperature
23 program 90° C (hold 2 min), 20° C min⁻¹, 200° C (hold 1.3 min), 1° C min⁻¹, 230° C (7
24 min), 10° C min⁻¹, 300° C (hold 20 min); for PCBs separation, injection of 10 μ L
25 sample in LVI (large volume injection) mode at 95° C (hold 0.5 min), applying injector
26 temperature program of 100° C min⁻¹, 300°C (hold 12.55 min), and column temperature
27 program of 60°C (hold 3 min), 20°C min⁻¹, 235°C (hold 10 min), 10°C min⁻¹, 260°C
28 (hold 0 min), 20°C min⁻¹, 300°C (hold 9 min). Detection was performed with an ion
29 trap mass spectrometer Varian 4000 GC/MS, based on the pattern of fragmentation of
30 the congeners by MS/MS. Quantification was based on the isotope dilution method;
31 calibration was previously performed using native and labelled dioxins/furans solutions
32 from Wellington Laboratories (EPA-1613CVS, CS1-CS-5) and dl-PCBs (WP-CVS
33 WHO/EPA, CS1-CS7) .
34
35
36
37
38
39
40
41
42
43
44
45
46

47
48 High resolution mass spectrometry (HRGC-HRMS) operating in electron ionization
49 (EI) mode and at a resolving power of 10,000 was also applied as confirmation method
50 for PCDD/Fs and dl-PCBs since the values for some congeners obtained in many of the
51 samples were below our detection limits; monitored masses in SIR mode were M and
52 M+2 or M+4.
53
54
55

56 57 58 *Quality*

1
2
3 All PCDD/F and dl-PCB data were assessed for compliance with the methods
4 performance criteria guidelines laid down in EU Commission Directives 2002/69/EC
5 and 2002/70/EC.
6
7

8
9
10 Dioxin, furans and dioxin-like PCBs were quantified by isotopic dilution, based on the
11 linearity of the detector signal of each isomer. The stability of the relative response
12 factor has been checked during successive calibrations, supporting the stability and
13 robustness of the methods.
14
15

16
17
18 Recoveries for each labelled congener have been studied in diverse matrix samples.
19 Recovery average values are 60-70%, ranging from 50 to 85%; it is quite constant
20 among congeners and also among tested sample matrices.
21
22

23
24
25 Repeatability and reproducibility were checked, using MS/MS method and HRMS as
26 confirmation method.
27
28

29
30 Certified Reference Materials have been used during the 2004-2006 period (Carp
31 muscle CARP-2, National Research Council Canada NRC-CNRC, Cod liver oil
32 FAPAS test material, Central Science Laboratory). Blanks were also checked, and
33 routinely included in each set of analyses.
34
35

36 37 HRGC-MS/MS

38
39
40 Identity was confirmed by comparing retention time between native and labelled
41 analogue isomers and the ion ratio is fulfilled between M and M+2 considering an
42 interval $\pm 25\%$ of the theoretical ion ratio. Mass spectra similarity of sample and
43 standard peaks was checked.
44
45
46
47
48

49
50 The instrumental limit of detection established for each compound was estimated as the
51 concentration providing a signal-to-noise ratio of 3:1. On a fresh-weight basis, the limits
52 of detection were 0.05-0.2 pg/g for tetra- and penta-congeners PCDD/Fs, 0.2-1 pg/g for
53 hexa-, hepta- and octa-congeners PCDD/Fs, and 0.3-1.5 pg/g for dl-PCBs.
54
55
56
57

58 59 HRGC-HRMS

60

1
2
3 The limits of detection were 0.01-0.02 pg/g for tetra-, penta-, hexa- and hepta-
4 chlorinated congeners PCDD/Fs, 0.10-0.15 pg/g for octa-chlorinated congeners
5 PCDD/Fs.
6
7
8

25

26
27 Although most abundant isomers in both feeds are 2,3,7,8-TCDF, followed by OCDD
28 and 2,3,4,7,8-PCDF, and PCBs 118, 105, 156 and 167, most contributing to total TEQ
29 are 2,3,4,7,8-PCDF, 2,3,7,8-TCDF, 2,3,7,8-TCDD and 1,2,3,7,8-PCDD, and PCBs 126,
30 118, 156 and 105. Relatively low levels of PCDD/Fs and dl-PCBs were found in the
31 feeding stuffs (0.52 pg TEQ/g PCDD/Fs and 1.62 pg TEQ/g dl-PCBs), far below
32 maximum levels set by the European Commission (2.25 pg/g TEQ-WHO PCDD/Fs,
33 relative to a moisture content of 12%, and 4.75 pg/g dl-PCBs), and below the action
34 limit (1.75 pg/g TEQ-WHO PCDD/Fs and 3.5 pg/g dl-PCBs) stated by Directive
35 2006/13/EC.

57

58
59 [Insert Figure 4 about here]
60

1
2
3 The most abundant contaminants in the feedingstuff are the most abundant in the fish,
4 these are: 2,3,7,8-TCDF, OCDD, 1,2,3,7,8-PeCDF, 2,3,4,7,8- PeCDF and 1,2,3,4,6,7,8-
5 HpCDD, and PCBs 118, 105, 156 and 167. The most relevant compounds accounting
6 for the total toxicity in turbot are 2,3,4,7,8- PeCDF, 2,3,7,8-TCDF, 2,3,7,8-TCDD and
7 1,2,3,7,8-PeCDD, and PCB 126 (figures 3 – 4), the same congeners accounting for the
8 total toxicity in feeding stuff. As reported by other authors in salmon (Lundebye *et al.*,
9 2004), the concentration of dioxins and dl-PCBs in turbot reflect the levels present in
10 the feed.

60

TEQ PCDD/Fs and dl-PCBs in turbot analysed were below the maximum permitted levels (4 pg/g fresh weight TEQ-WHO PCDD/F and 4 pg/g fresh weight TEQ-WHO PCBs, Regulation EC No. 199/2006) and below the action limit (3 pg/g fresh weight TEQ-WHO PCDD/F and 3 pg/g fresh weight TEQ-WHO PCBs, Recommendation 2006/88/EC).

Other authors have reported similar results in Spanish farmed fish, showing low levels of PCDD/Fs in general, with a pattern characterized by the presence of toxic TCDF, TCDD, PeCDD and PeCDFs (Abad *et al.* 2003), in trout, sea bass, gilthead and turbot. Trouts from French aquaculture showed very similar values (Marchand *et al.* 2004) for the same parameters, with mean values of 0.17 and 0.58 pg/g fresh weight for WHO-TEQ PCDD/Fs and dl-PCBs respectively. Other farmed fish, such as salmon, has been widely analyzed in many European countries for these contaminants, showing higher values of PCDD/Fs and dl-PCBs than wild salmon, associated with the use of fish oil (Karl *et al.* 2004). Levels obtained in salmon are usually higher than values in turbot obtained in this paper, expressed on a wet weight basis, as reported by many authors (Jacobs *et al.* 2002, Karl *et al.* 2004).

Dietary uptake

Correlation coefficients (Pearson) for TEQ levels and fat content were calculated (SPSS 12.0 for Windows, SPSS Inc., 1989-2003), and values obtained showed a significant correlation at the 0.05 level (2-tailed) for tetra- and penta-chlorinated PCDD/F congeners and hexa- and hepta-chlorinated dioxins 1,2,3,6,7,8-HxCDD and 1,2,3,4,6,7,8-HpCDD as well as for total TEQ ($0.5 < R < 0.6$). The 12 dl-PCBs show a significant correlation at the 0.05 level (2-tailed) between mentioned parameters ($0.5 <$

1
2
3 R < 0.6), showing the expected pattern of accumulation with increasing fat in the
4 organism, for mentioned PCDD/Fs congeners and dl-PCBs. The other PCDD/Fs
5 showed very low levels both in the feeding stuff and fish muscle tissue, under the limit
6 of detection.
7
8
9

10
11 Dietary accumulation efficiencies were calculated for each toxic congener in turbot of
12 1-2 years old under study. Feed conversion ratio (kg food consumed / kg weight gain)
13 of 1.1 was applied to calculate the consumed quantity by each individual. Dietary
14 accumulation values obtained are shown in Table 2. Accumulation efficiency values
15 around 30-46% for the 12 dl-PCBs and 27-34% for PCDD/Fs tetra- and penta-chloro
16 substituted eaten by turbot ended up in the fish fillets. Tetra- and penta-chlorinated
17 PCDD/F congeners show a mean accumulation of 31%, while higher chlorinated
18 PCDD/F congeners show lower efficiencies (< 22 %). Total WHO-TEQ accumulation
19 efficiencies were higher for dl-PCBs than for TCDD/Fs and around 35% of the total
20 ingested TEQ dl-PCBs remain in the organism, versus 30% of TEQ PCDD/Fs.
21
22
23
24
25
26
27
28
29

30 [Insert Table 2 about here]
31
32

33 These data show that dioxin-like PCBs accumulate more efficiently than PCDD/Fs in
34 the fillets of farmed turbot. Similarly, Isosaari *et al.* (2002) reported higher
35 accumulation efficiency for dl-PCBs in rainbow trout (*Oncorhynchus mykiss*) and
36 Lundebye *et al.* (2004) reported higher retention of dl-PCBs than for PCDD/Fs in
37 cultured Atlantic salmon (*Salmo salar*). The high tendency of the toxic PCB congeners
38 to be retained in fish tissues might explain why PCBs have a high contribution to the
39 total WHO-TEQ in fish tissues.
40
41
42
43
44
45
46

47 Accumulation values reported by Isosaari *et al.* (2004) in salmon were higher both for
48 PCDD/Fs and PCBs: 57-64% of the total TEQ PCDD/Fs and 86-94% TEQ dl-PCBs.
49 These values have been obtained from whole fish, adult salmon, while ours correspond
50 to the edible portion of fish, the fillets, of young turbot up to 2 years old; we have to
51 consider that maturation takes place at the age of 5 years (natural environment), but
52 aquaculture industry usually produce turbot of around 2 Kg (2-3 years old).
53
54
55
56
57
58
59
60

1
2
3 According to data from these authors, approximately 30% of both pollutants (WHO-
4 TEQ) found in fish were located in skinned fillet (Isosaari *et al.* 2004), which is
5 concordant with accumulation efficiency values obtained for turbot in this study.
6
7

8
9
10 Log K_{ow} are in the range 6.6 – 8.0 for tetra- to octa-substituted PCDD/F congeners, and
11 increase with increasing number of chlorine atoms (Rittler *et al.*, 1996). Correlation
12 between log K_{ow} and bioaccumulation of several hydrophobic compounds shows that
13 the highest bioconcentration factors of non-ionic compounds and the longest half-lives
14 of several hydrophobic organochlorine compounds occur at log K_{ow} values of
15 approximately seven (Fisk *et al.*, 1998; Meylan *et al.*, 1999). This is concordant with the
16 higher accumulation mean values in tetra- and penta-substituted congeners (27.6 -
17 34.0%) obtained in present study.
18
19
20
21
22
23
24

25 Log K_{ow} for PCBs indicate the potential for bioaccumulation varies between different
26 congeners with the more chlorinated PCBs having a much higher potential for
27 bioaccumulation than less-chlorinated congeners (5.6 - 6.5 for tetra-, 6.2 – 6.5 for penta-
28 , 6.7 – 7.3 for hexa-chlorobiphenyl isomers) (Mackey *et al.*, 1992; Ritter *et al.*, 1996),
29 although our results do not support this observation, tetra-substituted congeners (77 and
30 81) showing similar accumulation values to higher chlorinated PCBs (see Table 2).
31 Isosaari *et al.*(2004) have obtained preferential accumulation of tetrachlorinated
32 biphenyls in salmon, finding no significant differences in the accumulation efficiencies
33 among PCBs with five to eight chlorines.
34
35
36
37
38
39
40
41

42 Biomagnification factors

43
44
45 Lipid-normalized biomagnification factors (BMFs) were calculated and results are
46 shown in Table 2. Congener-specific differences in biomagnification factor were similar
47 to the trends observed in accumulation efficiencies, which is concordant because both
48 parameters were based on the same fish fillets concentrations. Biomagnification (> 1)
49 was shown for tetra- and pentachlorinated PCDD/Fs (mean BMF 1.5), but not for all the
50 higher-chlorinated congeners. Biomagnification factors were similar for all dl-PCB
51 congeners, with the same mean of 1.5 as for tetra- and pentachlorinated PCDD/Fs, and
52 all the measured PCB congeners biomagnified, except PCB 169. Similar results have
53 been obtained for whole salmon (Isosaari *et al.* 2004), although higher BMF for all dl-
54 PCB congeners than for PCDD/Fs were obtained by these authors, who have described
55
56
57
58
59
60

1
2
3 that the lipid-normalized concentration ratios of salmon fillet to whole fish showed an
4 equal partitioning of these contaminants.
5
6

7
8 Dietary intakes of PCDD/Fs and dl-PCBs recently calculated in Spanish population
9 (Fernández *et al.* 2004) show that fish and seafood accounted for 11% of the intake,
10 being dl-PCBs an important component in the total WHO-TEQ, up to 80% of this value
11 in fish food. Considering the more efficient accumulation of PCBs in fish, that might
12 explain the high contribution to the total TEQ in fish tissues (Isosaari *et al.* 2004), and
13 the relatively important contribution of fish to dietary intake, it will be necessary to
14 ensure the use of uncontaminated fish feed in aquaculture industry.
15
16
17
18
19
20

21 **Conclusions**

22
23
24 These preliminary results for young turbot may be helpful to approach the pattern of
25 dioxins and related contaminants retention from the diet in aquaculture fish, showing
26 that the levels of toxic compounds in feed are reflected in fish fillets and
27 biomagnification for relevant compounds accounting for total toxicity takes place, the
28 dl-PCBs being more efficiently accumulated. Considering the biomagnification of the
29 most toxic PCDD/Fs and dl-PCBs and the more efficient accumulation of PCBs in fish,
30 as well as the relatively important contribution of fish to dietary intake of total WHO-
31 TEQ, it will be necessary to ensure the use of uncontaminated fish feed in aquaculture
32 industry. The inclusion of dl-PCBs in this study provides valuable information for
33 forthcoming risk assessments and contributes to establish a relationship between dioxins
34 and similar contaminants in farmed fish meat and diet, to help assure consumer
35 confidence on farmed fish.
