Abstract

The Semantic Web is a vision for the future of the Web in which information is given explicit meaning, making it easier for machines to automatically process and integrate information available on the Web. An ontology defines the terms used to describe and represent an area of knowledge. Ontologies are used by people, databases, and applications that need to share domain information (a domain is just a specific subject area or area of knowledge, like medicine, tool manufacturing, real estate, automobile repair, financial management, etc.). In this paper we combine this two concepts to annotate models with meta-data according to the corresponding domain ontology with all the new extracted information in order to improve the performance of the entire system.

Keywords: Business rules, knowledge based systems, Model Driven Architecture, reasoning, Semantic Web.

1 Introduction

The Semantic Web will build on XML’s ability to define customized tagging schemes and RDF’s flexible approach to representing data. The first level above RDF required for the Semantic Web is an ontology language what can formally describe the meaning of terminology used in Web documents. If machines are expected to perform useful reasoning tasks on these documents, the language must go beyond the basic semantics of RDF Schema. The OWL Use Cases and Requirements Document provides more details on ontologies, motivates the need for a Web Ontology Language in terms of six use cases, and formulates design goals, requirements and objectives for OWL. Business rules define and constrains business processes in enterprises. Therefore, many business-governing rules have to be implemented in business-supporting applications, in order to reflect the real business environment. The aim of this paper is to give the methodology to automatically generate a part of the business rules by combining Model Driven Architecture and the Semantic Web using Ontology Definition Meta-model. This paper will be divided in three parts. The first covers the basis of both main topics ontology, semantic web and standards. The second part, explain the Model Driven Architecture. The last is the central one, it starts with a review of several approaches and aim to

OWL has been designed to meet this need for a Web Ontology Language. OWL is part of the growing stack of W3C recommendations related to the Semantic Web.

- XML provides a surface syntax for structured documents, but imposes no semantic constraints on the meaning of these documents.
- XML Schema is a language for restricting the structure of XML documents and also extends XML with datatypes.
- RDF is a data-model for objects (“resources”) and relations between them, provides a simple semantics for this data-model, and these model’s can be represented in an XML syntax.
- RDF Schema is a vocabulary for describing properties and classes of RDF resources, with a semantics for generalization-hierarchies of such properties and classes.
- OWL adds more vocabulary for describing properties and classes: among others, relations between classes (e.g. disjointness), cardinality (e.g. “exactly one”), equality, richer typing of properties, characteristics of properties (e.g. symmetry), and enumerated classes.
bridge the gap between ontology development and software engineering methodologies. We will also discuss the possibilities and the benefits provided by mixing models and web reasoning.

2 The Ontology concept

The term ontology means a specification of a conceptualization. That is, an ontology is a description (like a formal specification of a program) of the concepts and relationships that can exist for an agent or a community of agents. Dixit T. R. Gruber. He has been designing ontologies for the purpose of enabling knowledge sharing and reuse. In that context, an ontology is a specification used for making ontological commitments. The formal definition of ontological commitment is given below:

An ontology defines the terms used to describe and represent an area of knowledge. Ontologies are used by people, databases, and applications that need to share domain information (a domain is just a specific subject area or area of knowledge, like medicine, tool manufacturing, real estate, automobile repair, financial management, etc.).

Ontologies include computer-usable definitions of basic concepts in the domain and the relationships among them (note that here and throughout this document, definition is not used in the technical sense understood by logicians). They encode knowledge in a domain and also knowledge that spans domains. In this way, they make that knowledge reusable.

The word ontology has been used to describe artifacts with different degrees of structure. These range from simple taxonomies (such as the Yahoo hierarchy), to metadata schemes (such as the Dublin Core), to logical theories. The Semantic Web needs ontologies with a significant degree of structure. These need to specify descriptions for the following kinds of concepts:

- Classes (general things) in the many domains of interest
- The relationships that can exist among things
- The properties (or attributes) those things may have

Ontologies are usually expressed in a logic-based language, so that detailed, accurate, consistent, sound, and meaningful distinctions can be made among the classes, properties, and relations. Some ontology tools can perform automated reasoning using the ontologies, and thus provide advanced services to intelligent applications such as: conceptual/semantic search and retrieval, software agents, decision support, speech and natural language understanding, knowledge management, intelligent databases, and electronic commerce.

Ontologies figure prominently in the emerging Semantic Web as a way of representing the semantics of documents and enabling the semantics to be used by web applications and intelligent agents. Ontologies can prove very useful for a community as a way of structuring and defining the meaning of the metadata terms that are currently being collected and standardized. Using ontologies, tomorrow’s applications can be “intelligent,” in the sense that they can more accurately work at the human conceptual level.

Ontologies are critical for applications that want to search across or merge information from diverse communities. Although XML DTDs and XML Schemas are sufficient for exchanging data between parties who have agreed to definitions beforehand, their lack of semantics prevent machines from reliably performing this task given new XML vocabularies. The same term may be used with (sometimes subtle) different meaning in different contexts, and different terms may be used for items that have the same meaning. RDF and RDF Schema begin to approach this problem by allowing simple semantics to be associated with identifiers. With RDF Schema, one can define classes that may have multiple subclasses and super classes, and can define properties, which may have sub properties, domains, and ranges. In this sense, RDF Schema is a simple ontology language. However, in order to achieve inter-operation between numerous, autonomously developed and managed schemas, richer semantics are needed. For example, RDF Schema cannot specify that the Person and Car classes are disjoint, or that a string quartet has exactly four musicians as members.

One of the goals of this paper is to specify what is needed in a web ontology language. These requirements will be motivated by potential use cases and general design objectives that take into account the difficulties in applying the standard notion of ontologies to the unique environment of the Web.

3 The Model Driven Architecture (MDA)

The Model-Driven Architecture starts with the well-known and long established idea of separating the specification of the operation of a system from the details of the way that system uses the capabilities of its platform. The Figure ?? gives a general view of the MDA approach. We can see that a construction of a new Information System begins with the development of one or more requirements models (CIM). Then we may de-
develop models independent from any platform (PIM). In
theories, the latter models must be partially generated
from the former. Platform independent models must
be permanent, \( i.e. \) they do not contain any informa-
tion about execution platform. For constructing the
concrete application, we must have platform specific
models (PSM). These models are obtained by trans-
forming PIM and adding technical information rela-
tive to platforms. PSM are not permanent models. All
these models are for facilitating code generation. The
MDA approach is widely used and advanced generators
exist.

3.1 MDA models and semantics

MDA principals are very interesting and allow econ-
omizing many times during application life cycle by
code and model generation. However, MDA specifi-
cation does not tell anything about semantics on models.
MDA is only interested by content and not context
then that using semantics will offers more interesting
way in automatic generation.

3.1.1 Eventual solutions for adding semantics
in models:

In MDA, an instance of MOF \( ? \) is use for represent-
ing models but our works are only concerned by UML
models. For adding semantics in UML models we can use:

- **UML profile**: UML can be used for modeling many
domains. The problem with this is that UML models are so
generic that it is impossible to know either it is object application, a meta-model, a
model, a database structures or anything else only
by looking at it \( ? \). For adding precision, the
OMG has standardized the concept of UML profile \( ? \). A UML profile is a set of techniques and
mechanisms allowing to adapt UML in a particular
and specific domain. UML profile can be used in
any UML model and do not modify the structure
of the meta-model. UML profiles are stereotypes
or labels which can be injected into models. Af-
fter having stuck labels on models, we can make
inference using it. As we can see, doing this can
solve our problem of semantics lack on model in a
low level, but this is not exploitable by machines
because there is no notion of logic and taxonomy
and semantic is not formally defined.

- **Object Constraint Language**: In UML it was not
possible to define the body of an operation (or a
method) so the OCL \( ? \) was standardized by OMG
for doing it. OCL allows expressing any kind of
constraints on UML models. For example, we can
express constraints like: “before renting a car you
must be sure that it is OK”. Well, OCL seems to
be a good solution for our problem but it is not the
case. The first problem with OCL is that he does
not support side effect operations and the second
is that he does not offer automatic inference for
machines.

- **Action Semantic**: remember that the main con-
straint with OCL was that he only supports no
side effects operations. To solve this constraint,
the OMG standardize Action Semantic \( ? \). Well,
now we have a formalism being able to express any
king of operations and constraints but it is not
enough. This formalism is complicated to use \( ? \),
was not created while thinking to machine com-
prehension and self-use, and do not have a textual
formalism.

As we can see, none of the UML “techniques” is suit-
able for adding semantics in models. In an other side
a new domain of computer is growing more and more:
semantic web. The aim of the semantic web is to make
the web both comprehensible by humans and machines
\( ? \). A part of semantic web is about ontology and rea-
soning. Modeling concept defined by ontologies can
be used to model the concepts in a domain, the rela-
tionships between them, and the properties that can
be used to describe instances of those concepts \( ? \). In
addition, the Web Ontology Language (OWL)\[24\] sup-
ports the inclusion of certain types of constraint in on-
tology, allowing new information to be deduced when
combining instance data with these logic’s description
\( ? \). At this point our dilemma was how can we use
3.2 The Ontology Definition Meta-model

The MDA and its four-layer architecture provide a solid basis for defining the Meridel’s of any modeling language, and thus a language for modeling ontology based on the MOF [7]. The ODM is a proposal for an OMG’s RFP (Request For Proposal) [8] resulting of an extensive previous research in the fields of the MDA and ontology [9, 10]. The main objective of the ODM is to bridge the gap between traditional software tools for modeling (like UML) and artificial intelligence techniques (Logic’s description) for making ontology. The principle of ODM is to merge two big domains of research which are Model Driven Architecture and Semantic Web. ODM is still in standardization process at the OMG [11] when this paper is being written. Basically the ODM allows making ontology using UML (by using an UML refile with existing tools like Rational Rose or Poseidon) and transforming it to OWL/RDF, Topic Map or Common Logic (Figure 2).

Merging MDA and Semantic Web technologies allow more automatic processing like: generation of constraints and business rules from models.

4 Adding semantics on models for automatic business rules generation

MDA technologies and Semantic web are complementary; the first is concerned about automating the physical management and interchange of mandate, while the latter is focused on the semantics embodied in the content of the mandate as well as on automated reasoning over that content [12]. The Semantic Web is the new-generation Web that tries to represent information such that it can be used by machines not just for display purposes, but for automation, integration, and reuse across applications. Model Driven Development (MDD) is being developed in parallel with the Semantic Web [13]. Emerging applications in finance, healthcare, security, communications, business intelligence, and many other vertical markets are content and context sensitive (semantics), and require enterprise scalability and performance [14]. Merging Semantic Web and MDA technologies can fill this lack. Merging these two domains will be benefice to both:

- MDA is only interested by content and not by context (semantics), semantic web will resolve this important problem.
- For semantic web: there are many existing ontologies development tools, and they are used by different groups of people for performing diverse tasks. Although each tool provides different functionalities, users tend to use just one tool, as they are not able to exchange their ontologies from one tool to another. Supporting a heterogeneity of modeling language, while providing standard representations and APIs for model repositories and other tools, is one of the aims of the MDA (XMI) [15]. Another interesting thing is that so mature UML tools could be used for making ontologies rather than using so theoretical languages from Artificial Intelligence domain.

Merging MDA and Semantic Web technologies allow more automatic processing like: generation of constraints and business rules from models.

4.1 Our Approach for business rules automatic generation

Our principal is to use the benefice and advanced researches in Semantic Web, to combine it to Model Driven Architecture in the goal of making automatic business rules generation.

For generating business rules automatically, will use principally the semantic in OWL format. In OWL reasoning, we can make automatic reasoning both with structures (TBox) or assertion on individuals and properties (ABox) [16]. In our case for example, if we have:

\[ \text{Predicate : Human} \rightarrow \text{Woman} \]

This declaration means that we have a properties Predicate going to domain Human to range Woman.
So we want to generate that:

\[
\text{IF} \quad \text{Object1 Predicate Object2} \\
\text{THEN} \quad \text{Object1 is of type Human} \\
\text{ET} \quad \text{Object2 is of type Woman}
\]

Figure 3: Our approach

The Figure ?? schematizes our approach: using ODM, our model is generated in OWL/RDF model and this last one is enriched with semantics. With this semantically rich model two solutions are possible for generating something with: serialized the rich model in XMI [?] and use something like JMI [?] for parsing manually the XMI. Another solution is making inference directly with the OWL model using a OWL reasoner. We adopt the last solution because it exist good OWL Reasoner and this solution uses less intermediary steps.

Note that we know that generating any kind of business rules is impossible but if we arrive to generate a part of them, it will be a good thing. The Figure ?? summarizes our approach throughout MDA layers. As we can see the first step will be a generation according to the Computation Independent Model (CIM) in a OMG SBVR like syntax (in natural language), and after this, the next step will be to generate executives rules according to the Platform Independent Model using our rule language [?] and models based on something like XMI. We can also see that in the figure, our business rules language or a future business rule formalism [?, ?, ?], will be used to formalize rules generated at the PIM Level. At this step we’ll use our “translators” for generating rules at the PSM level for a specific rule engine. If one day, a standard business rules language is adopted, we’ll either make a “translator” from our language towards the new standard or either store directly rules in the new formalism.

5 Conclusion

A business rules application is intentionally built to accommodate continuous change in business rules. The ability to change them effectively, are fundamental for improving business adaptability. The platform on which the application runs should support such continuous change. Offering to knowledgeable business people (experts) the possibilities to formulate, validate, and manage rules in a “zero-development” environment bring more value-added to this notion of “computer sciences in humanity’s service”. Allowing an automatic generation part of this business rules will be better. In this paper, we have seen that, by combining the two big domains, Model Driven Architecture and Semantic Web, a solution is possible.

Right now we can only make generation according to the Computation Independent Model (CIM) in a OMG SBVR like syntax (in natural language). The next step will be to generate executives rules according to the Platform Independent Model using our rule language [?] and models based on something like XMI. The last step will be to have an editor allowing to edit both models and semantics.

Making simples generic business rules generation possible from models will facilitates the use of the business rules approach which allows easier systems maintenance. It’s clear that generating all kind of business rules is an utopia and we must delimit the degree of generation we want to obtain.

Adding semantics on conceptual models will open an exciting and interesting domain of application like information merge.
