Abstract: This paper is devoted to the adaptation of the method developed in Dolbeault et al. \[2011, 2009\] to a Fokker-Planck equation for fiber lay-down which has been studied in Bonilla et al. \[2007/08\], Götz et al. \[2007\]. Exponential convergence towards a unique stationary state is proved in a norm which is equivalent to a weighted $L^2$ norm. The method is based on a micro / macro decomposition which is well adapted to the diffusion limit regime.

KEY WORDS kinetic equations; stochastic differential equations; Fokker-Planck equation; fiber dynamics; hypocoercivity; spectral gap; Poincaré inequality; hypoelliptic operators; degenerate diffusion; transport operator; large time behavior; convergence to equilibrium; exponential rate of convergence

January 10, 2012

1 Introduction

The understanding of the shapes generated by the lay-down of flexible fibers onto a conveyor belt is of great interest in the production process of nonwovens textiles that find their applications, e.g., in composite materials like filters, textile and hygiene industry. In Götz et al. \[2007\] a stochastic model for the fiber lay-down process, i.e. for the generation of a fiber web on a conveyor belt has been presented. Taking into account the fiber motion under the influence of turbulence, the process can be described by a system of stochastic differential equations. We shall focus on a very simple situation, which does not take into account the movement of the belt, and gives rise to a Fokker-Planck equation. Some numerical results will also be considered at the end of this paper.

An important criterion for the quality of the web and the resulting nonwoven material is how the solution converges to equilibrium. In particular, the speed of convergence to the stationary solution is important. The faster this convergence is, the more uniform the produced textile will be. From a technological point of view, process parameters should be adjusted such that the speed of convergence to equilibrium is optimal.

The trend to equilibrium for solutions of kinetic equations has been investigated in many papers using entropy methods; see for example Desvillettes and Villani \[2001\], Villani \[2009\]. A simplified approach has been suggested in Dolbeault et al. \[2011, 2009\]. This trend to equilibrium for the Fokker-Planck equation for fiber lay-down under consideration in this paper has already been investigated using Dirichlet forms and operator semi-group techniques in Grothaus and Klar \[2008\]; an ergodic theorem and explicit rates of convergence have been established. In the present paper we prove the convergence at an exponential rate towards a unique stationary state in a weighted $L^2$ norm by adapting the method developed in Dolbeault et al. \[2011, 2009\] to the setting of non-moving belts.

2 The model and main results

In the melt-spinning process of nonwoven textiles, hundreds of individual endless fibers obtained by the continuous extrusion through nozzles of a melted polymer are stretched and entangled by highly turbulent air flows to finally form a web on a conveyor belt (see Götz et al. \[2007\] for more details). We describe the motion of an individual fiber, neglecting interactions with the others.

An arclength parametrization of the laid down fiber in a coordinate system following the conveyor belt is given by \( x_0(t) \in \mathbb{R}^2, \ t \geq 0 \). The tangent vector is denoted by \( dx_0(t)/dt = \tau(\alpha(t)) \) with \( \tau(\alpha) = (\cos \alpha, \sin \alpha) \), \( \alpha \in S^1 = \mathbb{R}/2\pi\mathbb{Z} \). Since the lay-down process is assumed to happen at the constant normalized speed 1 (equal to the spinning speed), \( x_0(t) \) can also be interpreted as the position of the lay-down point at time \( t \). If the conveyor belt moves with velocity \( \kappa e_1 \), the history of the lay-down point in the laboratory frame (as opposed to the conveyor belt frame) is given by \( x(t) = x_0(t) + t \kappa e_1 \), i.e.,

\[
\frac{dx}{dt} = \tau(\alpha) + \kappa e_1. \tag{1}
\]

It is a natural restriction that the speed of the conveyor belt cannot exceed the lay-down speed: \( 0 \leq \kappa \leq 1 \), since otherwise a stationary lay-down point would be impossible. The lay-down process can now be determined by prescribing the dynamics of the angle \( \alpha(t) \), described as a stochastic process. It is driven by a deterministic force trying to move the lay-down point towards the equilibrium position \( x = 0 \) and by a Brownian motion modeling the effect of the turbulent air flow:

\[
d\alpha = -\tau^\perp(\alpha) \cdot \nabla V(x) \, dt + A \, dW, \tag{2}
\]

where \( W \) denotes a one-dimensional Wiener process, \( A > 0 \) measures its strength relative to the deterministic forcing, \( \tau^\perp = d\tau/d\alpha = (\sin \alpha, -\cos \alpha) \), and \( V(x) \) is a potential such that \( e^{-V} \) is integrable with the normalisation \( \int_{\mathbb{R}^2} e^{-V} \, dx = 1 \) and \( \nabla V(0) = 0 \).

The system (1)–(2) defines a stochastic process on \( \mathbb{R}^2 \times S^1 \). The corresponding probability density \( f(t,x,\alpha) \) satisfies the Fokker-Planck equation

\[
\partial_t f + (\tau + \kappa e_1) \cdot \nabla x f - \partial_\alpha (\tau^\perp \cdot \nabla_x V f + D \partial_\alpha f) = 0,
\]

(with the diffusivity \( D = \Lambda^2/2 \)) which will be the object of our study. The analysis of the long time behaviour is considerably simplified in the case of a nonmoving conveyor belt:

\[\kappa = 0.\]

We shall assume that this assumption holds true from now on. In this case the Fokker-Planck equation is written as an abstract ODE

\[
\partial_t f + T f = L f, \tag{3}
\]

with \( T f = \tau \cdot \nabla x f - \partial_\alpha (\tau^\perp \cdot \nabla_x V f) \) and \( L f = \partial_\alpha^2 f \).

It is easily seen that \( F(x,\alpha) = e^{-V(x)} \) is an equilibrium solution of (3), lying in the intersection of the null spaces of \( T \) and \( L \): \( T F = L F = 0 \).

A convenient functional analytic setting is introduced by the scalar product

\[
\langle f, g \rangle := \int_{\mathbb{R}^2 \times S^1} f g \, d\mu, \quad d\mu(x,\alpha) := \frac{dx \, dv(\alpha)}{F(x,\alpha)}, \quad dv(\alpha) := \frac{d\alpha}{2\pi},
\]

and by the associated norm \( \|f\|^2 = \langle f, f \rangle \). On the space \( L^2(\mathbb{R}^2 \times S^1, d\mu) \), the operator \( T \) is skew symmetric, and the operator \( L \) is symmetric and negative semi-definite. Thus, we have

\[
\frac{d}{dt} \|f - F\|^2 = D \langle L f, f \rangle = -D \|\partial_\alpha f\|^2. \tag{4}
\]

This identity reveals the main difficulty in proving convergence to equilibrium. The decay to equilibrium seems to stop, as soon as \( F \) is in the null space of \( L \) consisting of all \( \alpha \)-independent distributions. On the other hand, the decay equation (4) does not make use of the action of the operator \( T \) and, in particular, of the fact that the equilibrium \( F \) is the unique probability density in \( N(T) \cap N(L) \). Any \( \alpha \)-independent distribution function \( f \) is indeed unstable under the action of \( T \), unless \( f = F \). Hence, convergence to the equilibrium can be expected and will be proven to be exponential. This is a so-called hypocoercivity result as defined in Villani [2009]. A recently developed approach [Dolbeault et al. 2011, 2009] for proving hypocoercivity in the abstract setting (3) will be applied with a special emphasis on the behaviour of the decay rate as \( D \to 0 \) and \( D \to \infty \). It requires assumptions on the potential \( V \), which have already been used in Dolbeault et al. [2011]:

(H1) **Regularity:** \( V \in W^{2,\infty}_\text{loc}(\mathbb{R}^2) \).
(H2) **Normalization:** \( \int_{\mathbb{R}^2} e^{-V} \, dx = 1 \).
(H3) Spectral gap condition: there exists a positive constant $A$ such that
\[ \int_{\mathbb{R}^2} |\nabla_x u|^2 e^{-V} \, dx \geq A \int_{\mathbb{R}^2} u^2 \, e^{-V} \, dx \]
for any $u \in H^1(\mathbb{R}^2)$ such that $\int_{\mathbb{R}^2} u \, e^{-V} \, dx = 0$.

(H4) Pointwise condition: there exists $c_1 > 0$ such that
\[ |\nabla_x V(x)| \leq c_1 (1 + |\nabla_x V(x)|) \]
for any $x \in \mathbb{R}^2$.

Roughly speaking, (H2) and (H3) require a sufficiently strong growth of $V(x)$ as $|x| \to \infty$, whereas (H4) puts a limitation on the growth behavior. This leaves room, however, for a large class of confining potentials including $V(x) = (1 + |x|^2)^\beta$, $\beta \geq 1/2$.

In Dolbeault et al. [2011], the additional pointwise condition $\Delta_x V(x) \leq \frac{\theta}{2} |\nabla_x V(x)|^2 + c_0$ with $c_0 > 0$ and $\theta \in (0, 1)$ has been required. This is, however, a consequence of (H4) by $\Delta_x V(x) \leq \sqrt{2} \, |\nabla_x V(x)|$ and the Young inequality $\sqrt{2} c_1 |\nabla_x V| \leq |\nabla_x V|^2 / 4 + 2 c_1^2$, with $\theta = 1/2$ and $c_0 = c_1 + 2 c_1^2$.

**Theorem 1.** Let $f_0 \in L^2(\mathbb{R}^2 \times S^1, d\mu)$ and let (H1)–(H4) hold. Then, for every $\eta > 0$, the solution of \( \Phi \) subject to the initial condition $f(t = 0) = f_0$ satisfies
\[ \|f(t) - F\| \leq (1 + \eta) \|f_0 - F\| e^{-\lambda t} \quad \text{with} \quad \lambda = \frac{\eta}{1 + \eta} \frac{C_1 D}{1 + C_2 D^2}, \]
where $C_1$ and $C_2$ are two positive constants which depend only on the potential $V$.

As a consequence, we have
\[ \lambda = O(D) \quad \text{as} \quad D \to 0 \quad \text{and} \quad \lambda = O(D^{-1}) \quad \text{as} \quad D \to \infty. \]

Both results are sharp, as can be seen from the toy problem in Dolbeault et al. [2011]. As $D \to 0$, dissipation is provided by the $O(D)$ right hand side of \( \Phi \), which dominates $\lambda$. On the other hand, the dynamics for large $D$ can be described by a macroscopic limit: see Bonilla et al. [2007/08]. When $D \to \infty$, the correct time scale is $t = O(D)$ and corresponds to a parabolic scaling, and therefore $\lambda = O(D^{-1})$ had to be expected.

However our method is not sharp in the sense that we cannot expect to obtain the optimal coefficients in the limiting cases above. Again this can be seen from the toy problem in Dolbeault et al. [2011], where the spectral gap can be explicitly computed.

### 3 Proof of Theorem \( \Phi \)

#### 3.1 The modified entropy

We introduce the deviation $g := f - F$, satisfying \( \Phi \) subject to $g(t = 0) = f_0 - F$. Following Dolbeault et al. [2011], we denote the orthogonal projection to $\mathcal{N}(L)$ by
\[ \Pi g := \rho_g = \int_{S^1} g \, d\nu. \]

Note that $\int_{\mathbb{R}^2} \rho_g \, dx = 0$ holds. In the following, we shall also need
\[ T \Pi g = \tau \cdot (\nabla_x \rho_g + \rho_g \nabla_x V) = \tau \cdot e^{-V} \nabla_x (e^V \rho_g), \]
with the consequence
\[ \Pi T \Pi = 0, \]
which is essential for the applicability of the method of Dolbeault et al. [2011]. It implies that the macroscopic limit (corresponding to $D \to \infty$) in \( \Phi \) is diffusive: see Bonilla et al. [2007/08].

With the help of the operator
\[ A = (1 + (T \Pi)^* (T \Pi))^{-1} (T \Pi)^* \]
and an appropriately chosen $\varepsilon > 0$, the modified entropy functional is defined by
\[ H[g] := \frac{1}{2} \|g\|^2 + \varepsilon \langle Ag, g \rangle. \]
By [Dolbeault et al., 2011, Lemma 1], (6) implies
\[ \|A g\| \leq \frac{1}{2} \|(1 - \Pi)g\|. \]

Hence the modified entropy functional is bounded from above and below by the square of the norm for any \( \varepsilon \in (0, 1) \). More precisely we have:
\[ \frac{1 - \varepsilon}{2} \|g\|^2 \leq H[g] \leq \frac{1 + \varepsilon}{2} \|g\|^2. \]

A straightforward computation gives
\[ \frac{d}{dt} H[g] = -D[g], \quad (7) \]
with the entropy dissipation functional
\[ D[g] = -D \langle Lg, g \rangle + \varepsilon \langle AT\Pi g, g \rangle + \varepsilon \langle AT(1 - \Pi)g, g \rangle - \varepsilon \langle TA g, g \rangle - \varepsilon D \langle ALg, g \rangle. \]

### 3.2 Microscopic and macroscopic coercivity

The first term on the right hand side of (8) has already been computed in (4). With \( d\nu = d\alpha/(2\pi) \), the Poincaré inequality on \( S^1 \),
\[ \int_{S^1} |\partial_\alpha g|^2 d\nu \geq \int_{S^1} (g - \int_{S^1} g d\nu)^2 d\nu, \]
implies the \textit{microscopic coercivity} property
\[ -\langle Lg, g \rangle \geq \|(1 - \Pi)g\|^2. \]

The operator \( AT\Pi = (1 + (\text{TII})^*\text{TII})^{-1}(\text{TII})^*\text{TII} \) shares its spectral decomposition with \( (\text{TII})^*\text{TII} \). For the latter we have, using (5)
\[ \langle (\text{TII})^*\text{TII}g, g \rangle = \|\text{TII}g\|^2 = \frac{1}{2} \int_{\mathbb{R}^2 \times S^1} e^{-V} |\nabla_x u_g|^2 dx d\nu, \]
with \( u_g = e^V \rho_g \). The spectral gap condition (H3) implies the \textit{macroscopic coercivity} property
\[ \langle (\text{TII})^*\text{TII}g, g \rangle \geq \frac{\Lambda}{2} \|\rho_g\|^2, \]
leading to
\[ \langle AT\Pi g, g \rangle \geq \frac{\Lambda}{2 + \Lambda} \|\Pi g\|^2. \]

By (9) and (10), the sum of the first two terms in the entropy dissipation (8) is coercive. This will also be sufficient for controlling the remaining three terms, if the operators \( AT, TA, \) and \( AL \) are bounded, for \( \varepsilon > 0, \) small enough.

### 3.3 Boundedness of auxiliary operators

By [Dolbeault et al., 2011, Lemma 1], we know that
\[ \|TA g\| \leq \|(1 - \Pi)g\|. \]

The computation
\[ (\text{TII})^*Lg = -\text{II}Lg = -\nabla_x \cdot \Pi(\tau \partial^2_\alpha g) = \nabla_x \cdot \Pi(\tau g) = -(\text{TII})^*g \]
shows that \( AL = -A \) and, thus,
\[ \|AL g\| \leq \frac{1}{2} \|(1 - \Pi)g\|. \]

The most elaborate part of the analysis is to prove the boundedness of \( AT \). Following the approach of [Dolbeault et al., 2011], we consider its adjoint
\[ (AT)^* = -T^2\Pi(1 + (\text{TII})^*\text{TII})^{-1}. \]
For a given \( g \in L^2(\mathbb{R}^2 \times S^1, d\mu) \), we introduce \( h = (1 + (\Pi I)^* \Pi I)^{-1} g \) which, after solving for \( g \) and applying \( \Pi \), becomes
\[
\rho_g = \rho_h - \Pi T^2 \rho_h = e^{-V} u_h - \frac{1}{2} \nabla_x \cdot (e^{-V} \nabla_x u_h) \quad (13)
\]
with \( u_h = e^V \rho_h \). A straightforward computation gives
\[
(\Pi I)^* g = -T^2 \rho_h = e^{-V} [ (\tau^+ \cdot \nabla_x)^2 u_h - (\tau^+ \cdot \nabla_x V) (\tau^\perp \cdot \nabla_x u_h) ]
\]
and, as a consequence,
\[
\| (\Pi I)^* g \| \leq \| \nabla^2_x u_h \|_{L^2(\mathbb{R}^2, e^{-V} dx)} + \| \nabla_x V \| \| \nabla_x u_h \|_{L^2(\mathbb{R}^2, e^{-V} dx)}. \]

Therefore, in order to prove the boundedness of \( (\Pi I)^* \) (and, thus, of \( \Pi I \)), we need to prove the boundedness of the right hand side in terms of \( \| \rho_g \| \) for the solution \( u_h \) of the elliptic equation [15]. This \( L^2 \to H^2 \) (with weight \( e^{-V} \)) elliptic regularity result has been derived in Dolbeault et. al. [2011] under the assumptions (H1)–(H4) (see Proposition 5 for the first term and Lemma 8 for the second). Collecting these results gives \( \| (\Pi I)^* g \| \leq C_V \| g \| \) and therefore
\[
\| \Pi I (1 - \Pi) g \| \leq C_V \| (1 - \Pi) g \|, \quad (14)
\]
where \( C_V \) depends only on the potential.

3.4 Hypocoercivity

\[
D[g] \geq D \| (1 - \Pi) g \|^2 + \frac{2\Lambda}{2 + \Lambda} \| \Pi g \|^2 - \epsilon (C_V + 1 + \frac{D}{2}) \| (1 - \Pi) g \| \| g \|
\geq (D - \epsilon (C_V + 1 + \frac{D}{2})) \| (1 - \Pi) g \|^2 + \frac{2\Lambda}{2 + \Lambda} \| \Pi g \|^2 - \epsilon (C_V + 1 + \frac{D}{2}) \| (1 - \Pi) g \| \| \Pi g \| \quad (15)
\]
for an arbitrary \( \delta > 0 \). This shows already that coercivity can be achieved by first choosing \( \delta \) and then \( \epsilon \), both small enough. With the choice
\[
\delta = \frac{\Lambda}{(2 + \Lambda) (C_V + 1 + D/2)},
\]
the coefficients on the right hand side of [15] can be written as \( D - \epsilon r(D) \) and \( \epsilon s \) with
\[
r(D) := \frac{1}{2\Lambda} \left( 2\Lambda + (2 + \Lambda) \left( C_V + 1 + \frac{D}{2} \right) \right), \quad s := \frac{\Lambda}{2(2 + \Lambda)}.
\]

Then the optimal choice of \( \epsilon \), considering the form of the coefficients, would be
\[
\epsilon_\pi(D) := \frac{D}{r(D) + s}.
\]

However, we also have to guarantee \( \epsilon < 1 \) for the definiteness of \( H[g] \) and actually, even stronger, \( \frac{1 + \frac{\epsilon}{\epsilon_\pi(D)}}{1 + \frac{\epsilon}{\epsilon_\pi(D)} (1 + \eta)^2} \) will be needed below, which can be guaranteed by the requirement \( \epsilon \leq \frac{\epsilon_\pi(D)}{1 + \eta} \). Moreover the two conditions are equivalent at first order for \( \eta > 0 \), small. These considerations lead to the choice
\[
\epsilon = \frac{\eta}{1 + \eta} \tilde{\epsilon}(D), \quad \text{with } \tilde{\epsilon}(D) := \max \left\{ 1, \max_{D > 0} \tilde{\epsilon}(D) \right\},
\]
which is finite because of \( \tilde{\epsilon}(0) = \tilde{\epsilon}(\infty) = 0 \). With this choice,
\[
D_1 - \epsilon r(D) \geq \epsilon s \geq \frac{\eta}{1 + \eta} \frac{2C_1 D}{1 + C_2 D^2} =: 2\lambda,
\]
with appropriately chosen constants \( C_1, C_2 > 0 \), depending only on \( \Lambda \) and \( C_V \) and, thus, only on the potential \( V \). The estimate
\[
D[g] \geq 2\lambda \| g \|^2 \geq \frac{4\lambda}{1 + \epsilon} H[g] > 2\lambda H[g]
\]
follows. Using this in [7] and the Gronwall lemma imply
\[
H[f(t) - F] \leq H[f_0 - F] e^{-2\lambda t}.
\]

Finally we obtain for the norm
\[
\| f(t) - F \|^2 \leq \frac{2}{1 - \epsilon} H[f(t) - F] \leq \frac{2}{1 - \epsilon} H[f_0 - F] e^{-2\lambda t} \leq \frac{1 + \frac{\epsilon}{1 - \epsilon}}{1 + \frac{\epsilon}{1 - \epsilon}} \| f_0 - F \|^2 e^{-2\lambda t},
\]
which completes the proof of Theorem [4].
4 Concluding remarks

4.1 Numerical investigations

It is interesting to compare the rates predicted by the above results, which are only upper bounds, with numerical rates of convergence. We use a classical Monte-Carlo method with an Euler-Maruyama discretization scheme for all computations. A numerical investigation of the equations using a semi-Lagrangian method can be found in Klar et al. [2009].

The exponential decay of the $L^2$-difference to the stationary solution is observed in Figure 1. In Figure 2 the decay rates $\lambda$ have been obtained from the above simulations for various values of $A$ using a least square fit. The rate given by Theorem 1, i.e. $\lambda \sim C_1 D_1 + C_2 D_2$, $D = A^2/2$, fits qualitatively very well the curve obtained in Figure 2 when $A$ is away from 0. In particular, values of $A$ with an optimal rate of convergence can be determined from the numerical as well as the analytical results.

4.2 Perspectives

1. Models where stationary solutions are not known explicitly. The model considered in this paper can be extended in different directions, for instance by taking into account the movement of the belt, or by models where fibers have smoother trajectories than the ones considered in this paper, see Herty et al. [2009], Bonilla et al. [2007/08]. In these cases the stationary solutions are not always known explicitly. The application of the entropy method presented above is then an open problem.

2. 3-D models. To model fluid flow through a fiber web, the model has to be extended to three dimensional situations, see Klar et al. [2012]. For such a model exponential convergence to equilibrium, at least for the case $\kappa = 0$, can be proven with the same methods as in this paper.
