\textbf{Abstract}

We prove a strong approximation result for the empirical process associated to a stationary sequence of real-valued random variables, under dependence conditions involving only indicators of half lines. This strong approximation result also holds for the empirical process associated to iterates of expanding maps with a neutral fixed point at zero, as soon as the correlations decrease more rapidly than \(n^{-1-\delta}\) for some positive \(\delta\). This shows that our conditions are in some sense optimal.

1 Introduction

Let \((X_i)_{i \in \mathbb{Z}}\) be a strictly stationary sequence of real-valued random variables with common distribution function \(F\), and define the empirical process of \((X_i)_{i \in \mathbb{Z}}\) by

\[ R_X(s, t) = \sum_{1 \leq k \leq t} \left( 1_{X_k \leq s} - F(s) \right), \quad s \in \mathbb{R}, \quad t \in \mathbb{R}^+ . \tag{1.1} \]

For independent identically distributed (iid) random variables \(X_i\) with the uniform distribution over \([0, 1]\), Komlós, Major and Tusnády (1975) constructed a continuous centered Gaussian process \(K_X\) with covariance function

\[ \mathbb{E}(K_X(s, t)K_X(s', t')) = (t \wedge t')(s \wedge s' - ss') \]

in such a way that

\[ \sup_{s \in \mathbb{R}, t \in [0,1]} |R_X(s, [nt]) - K_X(s, [nt])| = O(\log^2 n) \quad \text{almost surely,} \tag{1.2} \]

(we refer also to Castelle and Laurent-Bonvalot (1998) for a detailed proof). The rate of convergence given in (1.2) improves on the one obtained earlier by Kiefer (1972) and the two-parameter Gaussian process \(K_X\) is known in the literature as the Kiefer process.

Such a strong approximation allows not only to derive weak limit theorems, as Donsker’s invariance principle (1952) for the empirical distribution function, but also almost sure results, as the functional
form of the Finkelstein’s law of the iterated logarithm (1971). Moreover, from a statistical point of view, strong approximations with rates allow to construct many statistical procedures (we refer to the monograph of Shorack and Wellner (1986) which shows how the asymptotic behavior of the empirical process plays a crucial role in many important statistical applications).

In the dependent setting, the weak limiting behavior of the empirical process $R_X$ has been studied by many authors in different cases. See, among many others: Dehling and Taqqu (1989) for stationary Gaussian sequences, Giraitis and Surgailis (2002) for linear processes, Yu (1993) for associated sequences, Borovkova, Burton and Dehling (2001) for functions of absolutely regular sequences, Rio (2000) for strongly mixing sequences, Wu (2008) for functions of iid sequences and Dedecker (2010) for $\beta$-dependent sequences.

Strong approximations of type (1.2), for the empirical process with dependent data, have been less studied. Berkes and Philipp (1977) proved that, for functions of strongly mixing sequences satisfying $\alpha(n) = O(n^{-b})$ (where $\alpha(n)$ is the strong mixing coefficient of Rosenblatt (1956)), and if $F$ is continuous, there exists a two-parameter continuous Gaussian process $K_X$ such that

$$\sup_{s \in \mathbb{R}, t \in [0,1]} |R_X(s, [nt]) - K_X(s, [nt])| = O(\sqrt{n} (\ln(n))^{-a}) \text{ almost surely},$$

for some $a > 0$. The covariance function $\Gamma_X$ of $K_X$ is given by

$$\Gamma_X(s, s', t, t') = \min(t, t') \Lambda_X(s, s'),$$

where

$$\Lambda_X(s, s') = \sum_{k \geq 0} \text{Cov}(1_{X_0 \leq s}, 1_{X_k \leq s'}) + \sum_{k > 0} \text{Cov}(1_{X_0 \leq s'}, 1_{X_k \leq s}).$$

As a corollary, Berkes and Philipp (1977) obtained that the sequence $\{(2n \ln \ln n)^{-1/2} R_X(s, [nt]), n \geq 3\}$ of random functions on $\mathbb{R} \times [0,1]$ is with probability one relatively compact for the supremum norm, and that the set of limit points is the unit ball of the of the reproducing kernel Hilbert space (RKHS) associated with $\Gamma_X$. Their result generalizes the functional form of the Finkelstein’s law of the iterated logarithm. Next, Yoshihara (1979) weakened the strong mixing condition required in Berkes and Philipp (1977), and proved the strong approximation (1.3) assuming $\alpha(n) = O(n^{-a})$ for some $a > 3$. However this condition still appears to be too restrictive: indeed Rio (2000, Th. 7.2 p. 96) proved that the weak convergence of $n^{-1/2} R_X(s, n)$ to a Gaussian process holds in $D(\mathbb{R})$ under the weaker condition $\alpha(n) = O(n^{-a})$ for some $a > 1$. In view of this result, one may think that the strong approximation by a Kiefer process, as given in (1.3), holds as soon as the dependence coefficients are of the order of $O(n^{-a})$ for some $a > 1$.

Since the classical mixing coefficients have some limited applicability, many papers have been written in the last decade to derive limit theorems under various weak dependence measures (see for instance the monograph by Dedecker et al (2007)). Concerning the empirical process, Dedecker (2010) proved that the weak convergence of $n^{-1/2} R_X(s, n)$ to a Gaussian process holds in $D(\mathbb{R})$ under a dependence condition involving only indicators of half line, whereas Wu (2008) obtained the same result under conditions on, what he called, the predictive dependent measures. These predictive dependence measures allow coupling by independent sequences and are well adapted to some functions of iid sequences. However they seem to be less adequate for functionals of nonirreducible Markov chains or dynamical systems having some invariant probability. The recent paper by Berkes, Hörmann and Shauer (2009) deals with strong approximations as in (1.3) in the weak dependent setting by considering, what they called, $S$-mixing conditions. Actually their $S$-mixing condition lies much closer to the predictive dependent measures considered by Wu (2008) and is also very well adapted to functions of iid sequences. Roughly speaking they obtained (1.3) as soon as $F$ is Lipschitz continuous, the sequence $(X_i)_{i \in \mathbb{Z}}$ can be approximated by a $2m$-dependent sequence, and one has a nice control of the deviation probability of the approximating error.
In this paper, we prove that the strong approximation (1.3) holds under a dependence condition involving only indicators of half line, which is quite natural in this context (see the discussion at the beginning of Section 2 in Dedecker (2010)). More precisely, if \( \beta_{2,X}(n) = O(n^{-1+\delta}) \) for some positive \( \delta \), where the coefficients \( \beta_{2,X}(n) \) are defined in the next section, we prove that there exists a continuous (with respect to its natural metric) centered Gaussian process \( K_X \) with covariance function given by (1.4) such that

\[
\sup_{s \in \mathbb{R}, t \in [0,1]} |R_X(s, \lfloor nt \rfloor) - K_X(s, \lfloor nt \rfloor)| = O(n^{1/2-\varepsilon}) \quad \text{almost surely,} \tag{1.5}
\]

for some \( \varepsilon > 0 \). As consequences of (1.5), we obtain the functional form of the Finkelstein’s law of the iterated logarithm and we recover the empirical central limit theorem obtained in Dedecker (2010). Notice that our dependence condition cannot be directly compared to the one used in the paper by Berkes, Hörmann and Shauer (2009).

In Theorem 3.1, we show that (1.5) also holds for the empirical process associated to an expanding map \( T \) of the unit interval with a neutral fixed point at 0, as soon as the parameter \( \gamma \) belongs to \( [0, 1/2] \) (this parameter describes the behavior of \( T \) in the neighborhood of zero). Moreover, we shall prove that the functional law of the iterated cannot hold at the boundary \( \gamma = 1/2 \), which shows that our result is in some sense optimal (see Remark 3.2 for a detailed discussion about the optimality of the conditions).

Let us now give an outline of the methods used to prove the strong approximation (1.5). We consider the dyadic fluctuations \( (R_X(s, 2^{L+1}) - R_X(s, 2^L))_{L \geq 0} \) of the empirical process on a grid with a number of points depending on \( L \), let say \( d_L \). Our proof is mainly based on the existence of multidimensional Gaussian random variables in \( \mathbb{R}^{d_L} \) that approximate, in a certain sense, the fluctuations of the empirical process on the grid. These multidimensional Gaussian random variables will be the skeleton of the approximating Kiefer process. To prove the existence of these Gaussian random variables, we apply a conditional version of the Kantorovich-Rubinstein Theorem, as given in Rüschendorf (1985) (see our Section 4.1.1). The multidimensional Gaussian random variables are constructed in such a way that the error of approximation in \( L^1 \) of the supremum norm between the fluctuations of the empirical process on the grid and the multidimensional Gaussian r.v.’s is exactly the expectation of the Wasserstein distance of order 1 (with the distance associated to the supremum norm) between the conditional law of the fluctuations of the empirical process on the grid and the corresponding multidimensional Gaussian law (see Definition 4.1 and the equality (4.5)). This error can be evaluated with the help of the Lindeberg method as done in Section 4.1.3. The oscillations of the empirical process; namely, the quantities involved in (4.21) and (4.22), are handled with the help of a suitable exponential inequality combined with the Rosenthal-type inequality proved by Dedecker (2010, Proposition 3.1). Moreover, it is possible to adapt the method of constructing the skeleton Kiefer process (by conditioning up to the future rather than to the past) to deal with the empirical process associated to intermittent maps.

The paper is organized as follows: in Section 2 (resp. Section 3) we state the strong approximation results obtained for the empirical process associated to a class of stationary sequences (resp. to a class of intermittent maps). Section 4 is devoted to the proof of the main results, whereas some technical tools are stated and proved in Appendix.

2 Strong approximation for the empirical process associated to a class of stationary sequences

Let \( (X_i)_{i \in \mathbb{Z}} \) be a strictly stationary sequence of real-valued random variables defined on the probability space \((\Omega, \mathcal{A}, \mathbb{P})\). Assume that \((\Omega, \mathcal{A}, \mathbb{P})\) is large enough to contain a sequence \((U_i)_{i \in \mathbb{Z}} = (\delta_i, \eta_i)_{i \in \mathbb{Z}}\)
of iid random variables with uniform distribution over \([0, 1]^2\), independent of \((X_i)_{i \in \mathbb{Z}}\). Define the nondecreasing filtration \((F_i)_{i \in \mathbb{Z}}\) by \(F_i = \sigma(X_k : k \leq i)\). Let \(F_{-\infty} = \bigcap_{i \in \mathbb{Z}} F_i\) and \(F_{\infty} = \bigvee_{i \in \mathbb{Z}} F_i\). We shall denote by \(E_i\) the conditional expectation with respect to \(F_i\).

Let us now define the dependence coefficients of the sequence \((X_i)_{i \in \mathbb{Z}}\) that we consider in this paper.

**Definition 2.1** Let \(P\) be the law of \(X_0\) and \(P_{(X_i, X_j)}\) be the law of \((X_i, X_j)\). Let \(P_{X_k|X_0}\) be the conditional distribution of \(X_k\) given \(X_0\), \(P_{X_k|F_i}\) be the conditional distribution of \(X_k\) given \(F_i\), and \(P_{(X_i, X_j)|F_i}\) be the conditional distribution of \((X_i, X_j)\) given \(F_i\). Define the functions \(f_i = 1_{[\infty, t]}\), and \(f_t^{(0)} = f_t - P(f_t)\). Define the random variables

\[
\begin{align*}
    b(X_0, k) &= \sup_{t \in \mathbb{R}} |P_{X_k|X_0}(f_t) - P(f_t)|, \\
    b_1(F_i, k) &= \sup_{t \in \mathbb{R}} |P_{X_k|F_i}(f_t) - P(f_t)|, \\
    b_2(F_t, i, j) &= \sup_{(s, t) \in \mathbb{R}^2} |P_{(X_i, X_j)|F_i}(f_t^{(0)} \otimes f_s^{(0)}) - P_{(X_i, X_j)}(f_t^{(0)} \otimes f_s^{(0)})|.
\end{align*}
\]

Define now the coefficients

\[
\beta(\sigma(X_0), X_k) = E(b(X_0, k)), \quad \beta_{1, X}(k) = E(b_1(F_0, k)), \quad \text{and} \quad \beta_{2, X}(k) = \max \{ \beta_1(k), \sup_{s \geq k} E((b_2(F_0, i, j))) \}.
\]

Define also

\[
\alpha_{1, X}(k) = \sup_{t \in \mathbb{R}} \|P_{X_k|X_0}(f_t) - P(f_t)\|_1,
\]

and note that \(\alpha_{1, X}(k) \leq \beta_{1, X}(k) \leq \beta_{2, X}(k)\).

Examples of non mixing sequences \((X_i)_{i \in \mathbb{Z}}\) in the sense of Rosenblatt (1956) for which the coefficients \(\beta_{2, X}(n)\) can be computed may be found in the paper by Dedecker and Prieur (2007). We shall present another example in the next section.

Our main result is the following:

**Theorem 2.1** Assume that \(\beta_{2, X}(n) = O(n^{-1-\delta})\) for some \(\delta > 0\). Then

1. for all \((s, s') \in \mathbb{R}^2\), the series \(\Lambda_X(s, s')\) defined by (1.4) converges absolutely.

2. For any \((s, s') \in \mathbb{R}^2\) and \((t, t') \in \mathbb{R}^+ \times \mathbb{R}^+\), let \(\Gamma_X(s, s', t, t') = \min(t, t')\Lambda_X(s, s')\). There exists a centered Gaussian process \(K_X\) with covariance function \(\Gamma_X\), whose sample paths are almost surely uniformly continuous with respect to the pseudo metric

\[
d((s, t), (s', t')) = |F(s) - F(s')| + |t - t'|,
\]

and such that (1.5) holds with \(\varepsilon = \delta^2/(22(\delta + 2)^2)\).

Note that we do not make any assumption on the continuity of the distribution function \(F\).

As in the paper of Berkes, Hörmann and Shauer (2009), we can formulate corollaries to Theorem 2.1. The first one is direct. To obtain the second one, we need to combine the strong approximation (1.5) with Theorem 2 in Lai (1974).

**Corollary 2.1** Assume that \(\beta_{2, X}(n) = O(n^{-1-\delta})\) for some \(\delta > 0\). Then the empirical process \(\{n^{-1/2}R_X(s, [nt]), s \in \mathbb{R}, t \in [0, 1]\}\) converges in \(D(\mathbb{R} \times [0, 1])\) to the Gaussian process \(K_X\) defined in Item 2 of Theorem 2.1.
Corollary 2.2 Assume that $\beta_{2,X}(n) = O(n^{-a})$ for some $a > 0$. Then, with probability one, the sequence $\{(2n \ln \ln n)^{-1/2} R_X(s, [nt]), n \geq 3\}$ of random functions on $\mathbb{R} \times [0,1]$ is relatively compact for the supremum norm, and the set of limit points is the unit ball of the reproducing kernel Hilbert space (RKHS) associated with the covariance function $\Gamma_X$ defined in Theorem 2.1.

3 Strong approximation for the empirical process associated to a class of intermittent maps

In this section, we consider the following class of intermittent maps, introduced in Dedecker, Gouëzel and Merlevède (2010):

Definition 3.1 A map $T : [0,1] \to [0,1]$ is a generalized Pomeau-Manneville map (or GPM map) of parameter $\gamma \in [0,1[$ if there exist $0 = y_0 < y_1 < \cdots < y_d = 1$ such that, writing $I_k = [y_k, y_{k+1})$,

1. The restriction of $T$ to $I_k$ admits a $C^1$ extension $T_{(k)}$ to $\overline{I_k}$.

2. For $k \geq 1$, $T_{(k)}$ is $C^2$ on $\overline{I_k}$, and $\inf_{x \in I_k} |T'_{(k)}(x)| > 1$.

3. $T_{(0)}$ is $C^2$ on $[0,y_1]$, with $T'_{(0)}(x) > 1$ for $x \in (0,y_1]$, $T_{(0)}(0) = 1$ and $T''_{(0)}(x) \sim c x^{\gamma-1}$ when $x \to 0$, for some $c > 0$.

4. $T$ is topologically transitive; that is, there exists some $x$ in $[0,1[$ such that $\{T^n(x) : n \in \mathbb{N}\}$ is a dense subset of $[0,1[$.

The third condition ensures that 0 is a neutral fixed point of $T$, with $T(x) = x + c' x^{1+\gamma} (1 + o(1))$ when $x \to 0$. The fourth condition is necessary to avoid situations where there are several absolutely continuous invariant measures, or where the neutral fixed point does not belong to the support of the absolutely continuous invariant measure. As a well known example of a GPM map, let us cite the Liverani-Saussol-Vaienti (1999) map (LSV map) defined by

$$T(x) = \begin{cases} x(1 + 2^\gamma x^\gamma) & \text{if } x \in [0,1/2] \\ 2x - 1 & \text{if } x \in (1/2,1]. \end{cases}$$

Theorem 1 in Zweimüller (1998) shows that a GPM map $T$ admits a unique absolutely continuous invariant probability measure $\nu$, with density $h_\nu$. Moreover, it is ergodic, has full support, and $h_\nu(x)/x^{-\gamma}$ is bounded from above and below.

Let $Q$ be the Perron-Frobenius operator of $T$ with respect to $\nu$, defined by

$$\nu(f \cdot g \circ T) = \nu(Q(f)g),$$

for any bounded measurable functions $f$ and $g$. Let $(X_i)_{i \in \mathbb{Z}}$ be a stationary Markov chain with invariant measure $\nu$ and transition Kernel $Q$. Dedecker and Prieur (2009, Theorem 3.1) have proved that

$$\beta_{2,X}(n) = O(n^{-a}) \quad \text{for any } a < (1-\gamma)/\gamma$$

(3.2)

(this upper bound was stated for the Liverani-Saussol-Vaienti map only, but is also valid in our context: see the last paragraph of the introduction in Dedecker and Prieur (2009)). As a consequence, if $\gamma < 1/2$, the stationary sequence $(X_i)_{i \in \mathbb{Z}}$ satisfies all the assumptions of Theorem 2.1.

Now $(T, T^2, \ldots, T^n)$ is distributed as $(X_n, X_{n-1}, \ldots, X_1)$ on $([0,1], \nu)$ (see for instance Lemma XI.3 in Hennion and Hervé (2001)). Hence any information on the law of $\sum_{i=1}^n (f \circ T^i - \nu(f))$ can be
obtained by studying the law of \( \sum_{i=1}^{n}(f(X_i) - \nu(f)) \). However, the reverse time property cannot be used directly to transfer the almost sure results for \( \sum_{i=1}^{n}(f(X_i) - \nu(f)) \) to the sum \( \sum_{i=1}^{n}(f \circ T^i - \nu(f)) \).

For any \( s \in [0,1] \) and \( t \in \mathbb{R} \), let us consider the empirical process associated to the dynamical system \( T \):

\[
R_T(s,t) = \sum_{1 \leq i \leq t} (1_{T^i \leq s} - F_\nu(s)) \text{ where } F_\nu(s) = \nu([0,s]). \quad (3.3)
\]

For any \( \nu \)-integrable function \( g \), let \( g(0) = g - \nu(g) \) and recall that \( f_s = 1_{(-\infty,s]} \). Our main result is the following:

**Theorem 3.1** Let \( T \) be a GPM map with parameter \( \gamma \in [0,1/2] \). Then

1. For all \((s,s') \in [0,1]^2\), the following series converges absolutely:

\[
\Lambda_T(s,s') = \sum_{k \geq 0} \nu(f_s^{(0)} \cdot f_{s'}^{(0)} \circ T^k) + \sum_{k>0} \nu(f_s^{(0)} \cdot f_{s'}^{(0)} \circ T^k). \quad (3.4)
\]

2. For any \((s,s') \in [0,1]^2\) and any \((t,t') \in \mathbb{R}^+ \times \mathbb{R}^+\), let \( \Gamma_T(s,s',t,t') = \min(t,t') \Lambda_T(s,s') \). There exists a continuous centered Gaussian process \( K_T^\gamma \) with covariance function \( \Gamma_T \) such that for some \( \varepsilon > 0 \),

\[
\sup_{(s,t) \in [0,1]^2} |R_T(s,[nt]) - K_T^\gamma(s,[nt])| = O(n^{1/2 - \varepsilon}) \quad \text{almost surely.}
\]

**Remark 3.1** According to the proof of Theorem 3.1, Item 2 holds for any \( \varepsilon \) in \( [0,(1 - 2\gamma)^2/22] \).

**Remark 3.2** In the case \( \gamma = 1/2 \), Dedecker (2010, Proposition 4.1) proved that, for the LSV map with \( \gamma = 1/2 \), the finite dimensional marginals of the process \( \{ (n \ln n)^{-1/2} R_T(\cdot,n) \} \) converge in distribution to those of the degenerated Gaussian process \( G \) defined by

\[
G(t) = \sqrt{\frac{1}{2n} \ln(1/2)(1 - F_\nu(t))} 1_{t \neq 0} Z,
\]

where \( Z \) is a standard normal. This shows that an approximation by a Kiefer process as in Theorem 3.1 cannot hold at the boundary \( \gamma = 1/2 \).

For the same reason, when \( \gamma = 1/2 \), the conclusion of Theorem 2.1 does not apply to the stationary Markov chain \( (X_i)_{i \in \mathbb{Z}} \) with invariant measure \( \nu \) and transition kernel \( Q \) given in (3.1). In fact, it follows from Theorem 3.1 in Dedecker and Prieur (2009) that \( \beta_2,\chi(k) > C/k \) for some positive constant \( C \), so that the Markov chain \( (X_i)_{i \in \mathbb{Z}} \) does not satisfy the assumptions of Theorem 2.1.

In the case \( \gamma = 1/2 \), with the same proof as that of Theorem 1.1 of Dedecker, Gouëzel and Merlevède (2010), we see that, for any \((s,t) \in [0,1]^2\) and \( b > 1/2 \),

\[
\lim_{n \to \infty} \frac{1}{\sqrt{n(\ln n)^b}} R_T(s,[nt]) = 0 \quad \text{almost everywhere.}
\]

This almost sure result is of the same flavour than in the corresponding iid case, when the random variables have exactly a weak moment of order 2, so that the normalization in the central limit theorem is \( (n \ln n)^{-1/2} \); see the discussion in Dedecker, Gouëzel and Merlevède (2010), last paragraph of Section 1.2.

### 4 Proofs

In this section we shall sometimes use the notation \( a_n \ll b_n \) to mean that there exists a numerical constant \( C \) not depending on \( n \) such that \( a_n \leq Cb_n \), for all positive integers \( n \).
4.1 Proof of Theorem 2.1

Notice first that for any \((s, s') \in \mathbb{R}^2\),

\[
\left| \text{Cov}(1_{X_0 \leq s}, 1_{X_0 \leq s'}) \right| \leq \| \mathbb{E}_0(1_{X_0 \leq s'} - F(s')) 1_{X_0 \leq s} \|_1 \leq \mathbb{E}(b(X_0, k)) \leq \beta_{1,X}(k).
\]

Since \(\sum_{k \geq 0} \beta_{1,X}(k) < \infty\), Item 1 of Theorem 2.1 follows.

To prove Item 2, we first introduce another probability on \(\Omega\). Let \(P_0^*\) be the probability on \(\Omega\) whose density with respect to \(P\) is

\[
C(\beta)^{-1}(1 + 4 \sum_{k=1}^{\infty} b(X_0, k)) \text{ with } C(\beta) = 1 + 4 \sum_{k=1}^{\infty} \beta(\sigma(X_0), X_k).
\]

Recall that \(P\) is the distribution of \(X_0\). Then the image measure \(P^*\) of \(P_0^*\) by \(X_0\) is absolutely continuous with respect to \(P\) with density

\[
C(\beta)^{-1}(1 + 4 \sum_{k=1}^{\infty} b(x, k)).
\]

Let \(F_{P^*}\) be the distribution function of \(P^*\), and let \(F_{P^*}(x - 0) = \sup_{z < x} F_{P^*}(z)\). Recall that the sequence \((\eta_i)_{i \in \mathbb{Z}}\) of iid random variables with uniform distribution over \([0, 1]\) has been introduced at the beginning of Section 2. Define then the random variables

\[
Y_i = F_{P^*}(X_i - 0) + \eta_i(F_{P^*}(X_i) - F_{P^*}(X_i - 0)).
\]

Let \(Y_0\) be the distribution of \(Y_0\), and \(F_Y\) be the distribution function of \(Y_0\). Some properties of the sequence \((Y_i)_{i \in \mathbb{Z}}\) are given in Lemma 5.1 of the appendix. In particular, it follows from Lemma 5.1 that \(X_i = F_{P^*}^{-1}(Y_i)\) almost surely, where \(F_{P^*}^{-1}\) is the generalized inverse of the cadlag function \(F_{P^*}\). Hence \(R_X(\cdot, \cdot) = R_Y(F_{P^*}(\cdot), \cdot)\) almost surely, where

\[
R_Y(s, t) = \sum_{1 \leq k \leq t} \left( 1_{Y_k \leq s} - F_Y(s) \right), s \in [0, 1], t \in \mathbb{R}^+.
\]

We now prove that, if \(\beta_{2,X}(n) = O(n^{-1-\delta})\) for some \(\delta > 0\), then the conclusion of Theorem 2.1 holds for the stationary sequence \((Y_i)_{i \in \mathbb{Z}}\) and the associated continuous Gaussian process \(K_Y\) with covariance function \(\Gamma_Y(s, s', t, t') = \min(t, t') \Lambda_Y(s, s')\) where

\[
\Lambda_Y(s, s') = \sum_{k \geq 0} \text{Cov}(1_{Y_0 \leq s}, 1_{Y_k \leq s'}) + \sum_{k > 0} \text{Cov}(1_{Y_0 \leq s'}, 1_{Y_k \leq s}).
\]

This imply Theorem 2.1, since \(\Gamma_X(s, s', t, t') = \Gamma_Y(F_{P^*}(s), F_{P^*}(s'), t, t')\).

The proof is divided in two steps: the construction of the Kiefer process with the help of a conditional version of the Kantorovich-Rubinstein theorem, and a probabilistic upper bound for the error of approximation.

4.1.1 Construction of the Kiefer process

For \(L \in \mathbb{N}\), let \(m(L) \in \mathbb{N}\) and \(r(L) \in \mathbb{N}^*\) be such that \(m(L) \leq L\) and \(4r(L) \leq m(L)\). For \(j \in \{1, \ldots, 2^{r(L)} - 1\}\), let \(s_j = j2^{-r(L)}\) and define for any \(l \in \{1, \ldots, 2^{L-m(L)}\}\),

\[
I_{l,\ell} = [2L + (\ell - 1)2^m(L), 2L + \ell 2^m(L)] \cap \mathbb{N} \quad \text{and} \quad U_{l,\ell}^{(j)} = \sum_{i \in I_{l,\ell}} (1_{Y_i \leq s_j} - F_Y(s_j)).
\]
The associated column vectors $U_{L,\ell}$ are then defined in $\mathbb{R}^{2^{r(L)}-1}$ by

$$U_{L,\ell} = (U_{L,\ell}^{(1)}, \ldots, U_{L,\ell}^{(2^{r(L)}-1)})'.$$

Let us now introduce some definitions.

**Definition 4.1** Let $m$ be a positive integer. Let $P_1$ and $P_2$ be two probabilities on $(\mathbb{R}^m, \mathcal{B}(\mathbb{R}^m))$. Let $d$ be a distance on $\mathbb{R}^m$ associated to a norm. The Wasserstein distance of order 1 between $P_1$ and $P_2$ with respect to the distance $d$ is defined by

$$W_d(P_1, P_2) = \inf \{ \mathbb{E}(d(X, Y)) \mid (X, Y) \text{ such that } X \sim P_1, Y \sim P_2 \} = \sup_{f \in \text{Lip}(d)} (P_1(f) - P_2(f)),$$

where Lip(d) is the set of functions from $\mathbb{R}^m$ into $\mathbb{R}$ that are 1-Lipschitz with respect to $d$; namely for any $x$ and $y$ of $\mathbb{R}^m$, $|f(x) - f(y)| \leq d(x, y)$.

**Definition 4.2** Let $r$ be a positive integer. For $x = (x^{(1)}, \ldots, x^{(2^{r-1})})'$ and $y = (y^{(1)}, \ldots, y^{(2^{r-1})})'$, we set

$$d_r(x, y) = \sup_{j \in \{1, \ldots, 2^{r-1}\}} |x^{(j)} - y^{(j)}|.$$

Let $L \in \mathbb{N}$ and $\ell \in \{1, \ldots, 2^{L-m(L)}\}$. Let

$$\Lambda_{Y,L} = (\Lambda_Y(s_j, s'_j))_{j,j'=1,\ldots,2^{r(L)}-1},$$

where the $\Lambda_Y(s_j, s'_j)$ are defined in (4.4). Let $G_{2^m(L)\Lambda_{Y,L}}$ denote the $\mathcal{N}(0, 2^m(L)\Lambda_{Y,L})$-law and $P_{U_{L,\ell}}|_{\mathcal{F}_{2^L+(\ell-1)2^m(L)}}$ be the conditional distribution of $U_{L,\ell}$ given $\mathcal{F}_{2^L+(\ell-1)2^m(L)}$.

According to Rüschendorf (1985) (see also Theorem 2 in Dedecker, Prieur and Raynaud de Fitte (2006)), there exists a random variable $V_{L,\ell} = (V_{L,\ell}^{(1)}, \ldots, V_{L,\ell}^{(2^{r(L)}-1)})'$ with law $G_{2^m(L)\Lambda_{Y,L}}$ measurable with respect to $\sigma(\delta_{2^L+2^m(L)}) \vee \sigma(U_{L,\ell}) \vee \mathcal{F}_{2^L+(\ell-1)2^m(L)}$, independent of $\mathcal{F}_{2^L+(\ell-1)2^m(L)}$ and such that

$$\mathbb{E}(d_r(L)(U_{L,\ell}, V_{L,\ell})) = \mathbb{E}(W_{d_r(L)}(P_{U_{L,\ell}}|_{\mathcal{F}_{2^L+(\ell-1)2^m(L)}}, G_{2^m(L)\Lambda_{Y,L}}))$$

$$= \mathbb{E}\left( \sup_{f \in \text{Lip}(d_r(L))} \left( \mathbb{E}(f(U_{L,\ell})|_{\mathcal{F}_{2^L+(\ell-1)2^m(L)}}) - \mathbb{E}(f(V_{L,\ell})) \right) \right).$$

By induction on $\ell$, the random variables $(V_{L,\ell})_{\ell=1,\ldots,2^{L-m(L)}}$ are mutually independent, independent of $\mathcal{F}_{2^L}$ and with law $\mathcal{N}(0, 2^m(L)\Lambda_{Y,L})$. Hence we have constructed Gaussian random variables $(V_{L,\ell})_{L \in \mathbb{N}, \ell=1,\ldots,2^{L-m(L)}}$ that are mutually independent. In addition, according to Lemma 2.11 of Dudley and Philipp (1983), there exists a Kiefer process $K_Y$ with covariance function $\Gamma_Y$ such that for any $L \in \mathbb{N}$, any $\ell \in \{1, \ldots, 2^{L-m(L)}\}$ and any $j \in \{1, \ldots, 2^{r(L)}-1\}$,

$$V_{L,\ell}^{(j)} = K_Y(s_j, 2^L + \ell 2^m(L)) - K_Y(s_j, 2^L + (\ell - 1)2^m(L)).$$

Our construction is now complete.

In Proposition 4.1 proved in Section 4.1.3, we shall bound up the quantities $\mathbb{E}(d_r(L)(U_{L,\ell}, V_{L,\ell}))$ for $L \in \mathbb{N}$ and $\ell \in \{1, \ldots, 2^{L-m(L)}\}$, showing that under our condition on the dependence coefficients there exists a positive constant $C$ such that

$$\mathbb{E}(d_r(L)(U_{L,\ell}, V_{L,\ell})) \leq C 2^{(m(L)+2r(L))/((2+\delta)\wedge 3)} L^2.$$

In Section 4.1.2 below, starting from (4.7), we shall bound up the error of approximation between the empirical process and the Kiefer process.
4.1.2 Upper bound for the approximation error

Let \( \{K_Y(s, t), s \in [0, 1], t \geq 0\} \) be the Gaussian process constructed as in the step 1 with the following choice of \( r(L) \) and \( m(L) \). For \( \varepsilon < 1/10 \), let

\[
\begin{aligned}
   & r(L) = \left(\lfloor L/5 \rfloor \wedge [2\varepsilon L + 5 \log_2(L)]\right) \vee 1 \text{ and } m(L) = L - r(L),
\end{aligned}
\]  

so that, for \( L \) large enough,

\[
\begin{aligned}
   & 2^{2\varepsilon L - 1} L^5 \leq 2^r(L) \leq 2^{2\varepsilon L} L^5 \text{ and } 2^{L(1-2\varepsilon)} L^{-5} \leq 2^m(L) \leq 2^{1+L(1-2\varepsilon)} L^{-5}.
\end{aligned}
\]

Let \( N \in \mathbb{N}^* \) and let \( k \in [1, 2^{N+1}] \). To shorten the notations, let \( K_Y = K \) and \( R_Y = R \). We first notice that

\[
\begin{aligned}
   & \sup_{1 \leq k \leq 2^{N+1}} \sup_{s \in [0, 1]} |R(s, k) - K(s, k)| \leq \sup_{s \in [0, 1]} |R(s, 1) - K(s, 1)| + \sum_{L=0}^{N} D_L,
\end{aligned}
\]

where

\[
\begin{aligned}
   D_L := \sup_{2^L < \ell \leq 2^{L+1}} \sup_{s \in [0, 1]} |(R(s, \ell) - R(s, 2^L)) - (K(s, \ell) - K(s, 2^L))|.
\end{aligned}
\]

Notice first that \( \sup_{s \in [0, 1]} |R(s, 1) - K(s, 1)| \leq 1 + \sup_{s \in [0, 1]} |K(s, 1)| \). Dedecker (2010) (see the beginning of the proof of his Theorem 2.1) has proved that, for \( u \) and \( v \) in \([0, 1]\) and any positive integer \( n \),

\[
\begin{aligned}
   \text{Var}(K(u, n) - K(v, n)) \leq C(\beta) n|u - v|.
\end{aligned}
\]

Therefore according to Theorem 11.17 in Ledoux and Talagrand (1991), \( \mathbb{E}(\sup_{s \in [0, 1]} |K(s, 1)|) = O(1) \).

It follows that for any \( \varepsilon \in [0, 1/2]\),

\[
\begin{aligned}
   \sup_{s \in [0, 1]} |R(s, 1) - K(s, 1)| = O(2^{2N(\frac{1}{2} - \varepsilon)}) \text{ a.s.}
\end{aligned}
\]

To prove Theorem 2.1, it then suffices to prove that for any \( L \in \{0, \ldots, N\} \),

\[
\begin{aligned}
   D_L = O(2^{L(\frac{1}{2} - \varepsilon)}) \text{ a.s. for } \varepsilon = \delta^2/(22(\delta + 2)^2).
\end{aligned}
\]

With this aim, we decompose \( D_L \) with the help of several quantities. For any \( K \in \mathbb{N} \) and any \( s \in [0, 1] \), let \( \Pi_K(s) = 2^{-K}[2^K s] \). Notice that the following decomposition is valid: For any \( L \in \mathbb{N} \),

\[
\begin{aligned}
   D_L \leq D_{L,1} + D_{L,2} + D_{L,3},
\end{aligned}
\]

where

\[
\begin{aligned}
   D_{L,1} &= \sup_{2^L < \ell \leq 2^{L+1}} \sup_{s \in [0, 1]} |(R(s, \ell) - R(\Pi_{r(L)}(s), \ell)) - (R(s, 2^L) - R(\Pi_{r(L)}(s), 2^L))|,
\end{aligned}
\]

\[
\begin{aligned}
   D_{L,2} &= \sup_{2^L < \ell \leq 2^{L+1}} \sup_{s \in [0, 1]} |(K(s, \ell) - K(\Pi_{r(L)}(s), \ell)) - (K(s, 2^L) - K(\Pi_{r(L)}(s), 2^L))|,
\end{aligned}
\]

\[
\begin{aligned}
   D_{L,3} &= \sup_{2^L < \ell \leq 2^{L+1}} \sup_{s \in [0, 1]} |(R(\Pi_{r(L)}(s), \ell) - R(\Pi_{r(L)}(s), 2^L)) - (K(\Pi_{r(L)}(s), \ell) - K(\Pi_{r(L)}(s), 2^L))|.
\end{aligned}
\]

In addition,

\[
\begin{aligned}
   D_{L,3} \leq A_{L,3} + B_{L,3} + C_{L,3},
\end{aligned}
\]

9
where
\[
A_{L,3} = \sup_{j \in \{1, \ldots, 2^{(r(L))-1}\}} \sup_{k \leq 2^{L-m(L)}-1} \left| \sum_{\ell=1}^{k} (V_{L,\ell}^{(j)} - V_{L,\ell}^{(j)}) \right| ,
\]
\[
B_{L,3} = \sup_{j \in \{1, \ldots, 2^{(r(L))-1}\}} \sup_{k \leq 2^{L-m(L)}-1} \sup_{\ell \in I_{L,k}} \left| R(s_j, \ell) - R(s_j, 2^L + (k-1)2^{m(L)}) \right| ,
\]
\[
C_{L,3} = \sup_{j \in \{1, \ldots, 2^{(r(L))-1}\}} \sup_{k \leq 2^{L-m(L)}-1} \sup_{\ell \in I_{L,k}} \left| K(s_j, \ell) - K(s_j, 2^L + (k-1)2^{m(L)}) \right| ,
\]
with \( s_j = j2^{-r(L)} \).

Let us first deal with the terms \( D_{L,2} \) and \( C_{L,3} \) involving only the approximating Kiefer process.

For any positive \( \lambda \),
\[
P(D_{L,2} \geq \lambda) \leq \sum_{j=1}^{2^{r(L)}} \mathbb{P}\left( \max_{2^L \leq j \leq 2^{L+1}} \sup_{s \leq s_j} \left| (K(s, \ell) - K(s, 2^L)) - (K(s_j, \ell) - K(s_j, 2^L)) \right| \geq \lambda \right).
\]

Setting
\[
X(u, v) = (K(s_j + u(s_{j+1} - s_j), 2^L + v2^L) - K(s_j + u(s_{j+1} - s_j), 2^L)) - (K(s_j, 2^L + v2^L) - K(s_j, 2^L)),
\]
we have
\[
P(D_{L,2} \geq \lambda) \leq \sum_{j=1}^{2^{r(L)}} \mathbb{P}\left( \sup_{(u, v) \in [0,1]^2} |X(u, v)| \geq \lambda \right).
\]

Using (4.12), we infer that
\[
\mathbb{E}|X(u, v) - X(u', v')|^2 \ll 2^{L-r(L)}(|u - u'| + |v - v'|) \quad \text{and} \quad \sup_{(u, v) \in [0,1]^2} \mathbb{E}|X(u, v)|^2 \ll 2^{L-r(L)}.
\]

Next using Lemma 2 in Lai (1974) as done in Lemma 6.2 in Berkes and Philipp (1977), and taking into account (4.9), we infer that there exists a positive constant \( c \) such that, for \( L \) large enough,
\[
P(D_{L,2} \geq c2^{L(1/2-\varepsilon)}) \ll 2^{r(L)} \exp(-L^5/2).
\]

Therefore
\[
\sum_{L>0} P(D_{L,2} \geq c2^{L(1/2-\varepsilon)}) < \infty. \quad (4.17)
\]

Consider now the term \( C_{L,3} \). For any positive \( \lambda \),
\[
P(C_{L,3} \geq \lambda) \leq \sum_{k=1}^{2^{L-m(L)}} \mathbb{P}\left( \sup_{s \in [0,1]} \sup_{\ell \in I_{L,k}} |K(s, \ell) - K(s, 2^L + (k-1)2^{m(L)})| \geq \lambda \right).
\]

Setting \( X(s, u) = K(s, 2^L + (k-1)2^{m(L)} + u2^{m(L)}) - K(s, 2^L + (k-1)2^{m(L)} + u2^{m(L)}) \), and using (4.12), we have that
\[
\mathbb{E}|X(s, u) - X(s', u')|^2 \ll 2^{m(L)}(|s - s'| + |u - u'|) \quad \text{and} \quad \sup_{(s, u) \in [0,1]^2} \mathbb{E}|X(s, u)|^2 \ll 2^{m(L)}.
\]

Therefore by using once again Lemma 2 in Lai (1974) as done in Lemma 6.3 in Berkes and Philipp (1977), and taking into account (4.9), we infer that there exists a positive constant \( c \) such that, for \( L \) large enough,
\[
P\left( \sup_{s \in [0,1]} \sup_{\ell \in I_{L,k}} |K(s, \ell) - K(s, 2^L + (k-1)2^{m(L)})| \geq c2^{L(1/2-\varepsilon)} \right) \ll \exp(-L^5/2).
\]

10
Therefore

\[ \sum_{L>0} \mathbb{P}(C_{L,3} \geq cL^{(1/2-\varepsilon)}) < \infty. \quad (4.18) \]

We now prove that

\[ \sum_{L>0} \mathbb{P}(A_{L,3} \geq 2L^{1/2-\varepsilon}) < \infty. \quad (4.19) \]

From the stationarity of the sequence \((U_{L,\ell}, V_{L,\ell})_{\ell=1,\ldots,2^L-m(L)}\),

\[ \mathbb{P}(A_{L,3} \geq 2L^{(1/2-\varepsilon)}) \leq 2L-m(L)2L^{(1/2-\varepsilon)}L^2, \]

which together with (4.9) proves (4.19), provided that

\[ \varepsilon < \frac{\delta \wedge 1}{2(8 + 3(\delta \wedge 1))}. \quad (4.20) \]

We now show that

\[ \sum_{L>0} \mathbb{P}(B_{L,3} \geq C2^{L(1/2-\varepsilon)}) < \infty. \quad (4.21) \]

By stationarity, for any positive \(\lambda\),

\[ \mathbb{P}(B_{L,3} \geq \lambda) \leq 2L-m(L)2^{(L)} \sum_{j=1}^{2^{(L)}} \mathbb{P}\left( \sup_{\ell \leq 2^m(L)} \left| \sum_{i=1}^{\ell} (1_{Y_i \leq j^2-\ell(\lambda)} - F_Y(j^2-\lambda)) \right| \geq \lambda \right). \]

By Lemma 5.1 \(|\text{Cov}(1_{Y_0 \leq j^2-\lambda}, 1_{Y_i \leq j^2-\lambda})| \leq \mathbb{E}(b(X_0, i)) = \beta(\sigma(X_0), X_i)\), and consequently

\[ \sum_{i \in \mathbb{Z}} |\text{Cov}(1_{Y_0 \leq j^2-\lambda}, 1_{Y_i \leq j^2-\lambda})| \leq C(\beta). \]

Applying Theorem 1 in Dedecker and Merlevède (2010), we get that for any \(v \geq 1\),

\[ \mathbb{P}\left( \sup_{\ell \leq 2^m(L)} \left| \sum_{i=1}^{\ell} (1_{Y_i \leq j^2-\lambda} - F_Y(j^2-\lambda)) \right| \geq 4\lambda \right) \ll \left(1 + \frac{\lambda^2}{2^{m(L)}vC(\beta)}\right)^{-v/4} + \left(\frac{2^{m(L)}}{\lambda + v}\right)\beta_{2,v} \left(\left\lfloor \frac{\lambda}{v} \right\rfloor \right). \]

Applying this inequality with \(4\lambda = 2L^{(1/2-\varepsilon)}\) and \(v = L^5/C(\beta)\) and taking into account (4.9) together with our condition on the dependence coefficients, we derive that for \(L\) large enough,

\[ \mathbb{P}\left( \sup_{\ell \leq 2^m(L)} \left| \sum_{i=1}^{\ell} (1_{Y_i \leq j^2-\lambda} - F_Y(j^2-\lambda)) \right| \geq 2L^{(1/2-\varepsilon)} \right) \ll \exp(-c_1L^5) + L^{5\delta_2-5L^{(1/2-\varepsilon)}\delta}. \]

Therefore (4.21) holds provided that \(\varepsilon < \delta/(8 + 2\delta)\) which holds under (4.20).

Taking into account (4.17), (4.18), (4.19) and (4.21) together with the decompositions (4.15) and (4.16), the proof of (4.14) will be complete if we prove that, for some positive constant \(A\) to be choosen later,

\[ \sum_{L>0} \mathbb{P}(D_{L,1} \geq \sqrt{AC(\beta)}2L^{(1/2-\varepsilon)}) < \infty. \quad (4.22) \]
To shorten the notations, we set for $l > m \geq 0$, 

$$\mu_{l,m}(s) = R(s, l) - R(s, m) \text{ and } Z_{l,m} = d\mu_{l,m}.$$ 

We start from the elementary decomposition

$$\mu_{l,2l}(s) - \mu_{l,2l}(\Pi_{r(L)}(s)) = \sum_{K=r(L)+1}^{L} \mu_{l,2l}(\Pi_{K}(s)) - \mu_{l,2l}(\Pi_{K-1}(s)) + \mu_{l,2l}(s) - \mu_{l,2l}(\Pi_{L}(s)).$$

Consequently,

$$\sup_{s \in [0, 1]} |\mu_{l,2l}(s) - \mu_{l,2l}(\Pi_{r(L)}(s))| \leq \sum_{K=r(L)+1}^{L} \Delta_{K,l,2l} + \Delta_{L,l,2l}, \quad (4.23)$$

where

$$\Delta_{K,l,m} = \sup_{1 \leq i \leq 2^K} |Z_{\ell,m}(|(i-1)2^{-K}, i2^{-K})| \text{ and } \Delta_{L,l,m} = \sup_{s \in [0, 1]} |Z_{l,m}(\Pi_{L}(s), s)|.$$

Note that

$$-(l - 2L)P(\Pi_{L}(s) < Y_0 \leq \Pi_{L}(s) + 2^{-L}) \leq Z_{l,2l}(\Pi_{L}(s), s), \quad (4.24)$$

and

$$Z_{l,2l}(\Pi_{L}(s), s) \leq Z_{l,2l}(\Pi_{L}(s), \Pi_{L}(s) + 2^{-L}) + (l - 2L)P(\Pi_{L}(s) < Y_0 \leq \Pi_{L}(s) + 2^{-L}). \quad (4.25)$$

Applying Lemma 5.1,

$$P(\Pi_{L}(s) < Y_0 \leq \Pi_{L}(s) + 2^{-L}) \leq C(\beta)\mathbb{P}_0(\Pi_{L}(s) < Y_0 \leq \Pi_{L}(s) + 2^{-L}) = C(\beta)2^{-L}. \quad (4.26)$$

From (4.24), (4.25) and (4.26), we infer that $\Delta_{L,l,2l} \leq \Delta_{L,l,2l} + C(\beta)$. Hence it follows from (4.23) that

$$\sup_{s \in [0, 1]} |\mu_{l,2l}(s) - \mu_{l,2l}(\Pi_{r(L)}(s))| \leq C(\beta) + 2 \sum_{K=r(L)+1}^{L} \Delta_{K,l,2l}. \quad (4.27)$$

Therefore

$$\sup_{2^L < l \leq 2^{L+1}} \sup_{s \in [0, 1]} |\mu_{l,2l}(s) - \mu_{l,2l}(\Pi_{r(L)}(s))| \leq C(\beta) + 2 \sum_{K=r(L)+1}^{L} \sup_{2^L < l \leq 2^{L+1}} \Delta_{K,l,2l}. \quad (4.28)$$

Hence, to prove (4.22), it suffices to show that

$$\sum_{L > 0} P\left( \sum_{K=r(L)+1}^{L} 2^{L} \sum_{2^L < l \leq 2^{L+1}} \Delta_{K,l,2l} > \sqrt{AC(\beta)}2^{L(1/2-\epsilon)-2} \right) < \infty. \quad (4.27)$$

Let $c_K = (K+1)^{-1}$. Clearly, using the stationarity, (4.27) is true provided that

$$\sum_{L > 0} \sum_{K=r(L)+1}^{L} P\left( \sup_{0 < \ell \leq 2^{L}} \Delta_{K,l,0} > \sqrt{AC(\beta)c_K}2^{L(1/2-\epsilon)-2} \right) < \infty. \quad (4.28)$$

We now give two upper bounds for the quantity

$$P\left( \sup_{0 < \ell \leq 2^{L}} \Delta_{K,l,0} > \sqrt{AC(\beta)c_K}2^{L(1/2-\epsilon)-2} \right).$$
Choose \( p \in [2, 3] \) such that \( p < 2(1 + \delta) \). Applying Markov’s inequality at order \( p \), we have

\[
\Pr \left( \sup_{0 < t \leq 2L} \Delta_{K, t, 0} > \sqrt{AC(\beta)c_K 2^{L(\frac{1}{2} - \varepsilon) - 2}} \right) \leq c_K^{-p} 2^{L(p - p/2)} \left\| \sup_{0 < t \leq 2L} \Delta_{K, t, 0} \right\|_p^p.
\]

Applying Inequality (7) of Proposition 1 in Wu (2007) to the stationary sequence \((T_{K,i}^{(j)})_{j \in \mathbb{Z}}\) defined by \( T_{K,i}^{(j)} = 1_{(i-1)2^{-K} < Y_j \leq i2^{-K}} \), we have

\[
\left\| \sup_{0 < t \leq 2L} \Delta_{K, t, 0} \right\|_p \leq 2^{L/p} \sum_{j=0}^{L} 2^{-j/p} \left\| \Delta_{K, 2^j, 0} \right\|_p.
\]

Let \( 0 < \eta < (p - 2)/2 \). Dedecker (2010) (see the displayed inequality after (2.19) in his paper) proved that

\[
\left\| \Delta_{K, 2^j, 0} \right\|_p \leq 2^{j/2} \left( 2^{-K(p - 2)/2} + 2^{-j\eta(2(1 + \delta) - p)/2} + 2^{j/2 - (p/2 - 1)} \right).
\]

Therefore

\[
\left\| \sup_{0 < t \leq 2L} \Delta_{K, t, 0} \right\|_p \leq 2^{L/2} \left( 2^{-K(p - 2)/2} + 2^{-\eta L(2(1 + \delta) - p)/2} + 2^{\eta L - (p - 2)/2} \right).
\] (4.29)

On the other hand

\[
\Pr \left( \sup_{0 < t \leq 2L} \Delta_{K, t, 0} > \sqrt{AC(\beta)c_K 2^{L(\frac{1}{2} - \varepsilon) - 2}} \right)
\]

\[
\leq \sum_{i=1}^{2^K} \Pr \left( \sup_{0 < t \leq 2L} |Z_{t, 0}([i - 1)2^{-K}, i2^{-K})| > \sqrt{AC(\beta)c_K 2^{L(\frac{1}{2} - \varepsilon) - 2}} \right).
\]

We now apply Theorem 1 in Dedecker and Merlevède (2010), taking into account the stationarity: for any \( x > 0, v \geq 1 \), and \( s^2_L \geq 2^{2L} \sum_{j=0}^{2^L} |\text{Cov}(T_{K,i}^{(j)}, T_{K,i}^{(j+1)})| \),

\[
\Pr \left( \sup_{0 < t \leq 2L} |Z_{t, 0}([i - 1)2^{-K}, i2^{-K})| > \sqrt{2x} \right) \leq \left( 1 + \frac{x^2}{vs^2_L} \right)^{-v/4} + 2^L \left( \frac{1 + \frac{2x}{vs^2_L}}{2} \right) \beta_{2, X} \left( \left[ \frac{x}{v} \right] \right).
\]

Applying Lemma 5.1, we have \( |\text{Cov}(T_{K,i}^{(j)}, T_{K,i}^{(j+1)})| \leq 2E(T_{K,i}^{(j)}b(X_0, j)) \). Hence

\[
\sum_{j=0}^{\infty} |\text{Cov}(T_{K,i}^{(j)}, T_{K,i}^{(j+1)})| \leq C(\beta) \Pr((i - 1)2^{-K} < Y_0 \leq i2^{-K}) = C(\beta)2^{-K}.
\] (4.30)

It follows that, for \( K \geq r(L) \),

\[
\sum_{j=0}^{\infty} |\text{Cov}(T_{K,i}^{(j)}, T_{K,i}^{(j+1)})| \leq C(\beta)2^{-r(L)}.
\]

For \( L \geq 2 \), let \( x = x_{K,L} = \sqrt{AC(\beta)c_K 2^{L(1/2 - \varepsilon) - 4}} \), \( s^2_L = C(\beta)2^{L-r(L)} \) and \( v = v_L = 4L \). Taking into account (4.9) and noting that \( c_K \geq L(L + 1) \) for \( K \leq L \), we obtain for \( L \) large enough and \( K \leq L \),

\[
\left( 1 + \frac{x^2}{vs^2_L} \right)^{-v/4} \leq \left( 1 + \frac{A2^L(1-x)}{2^{10}L^3(L + 1)^22^{L-r(L)}} \right)^{-L} \leq 3^{-L}.
\]
the last bound being true provided $A$ is large enough. Hence, for $L$ large enough and $r(L) \leq K \leq L$,

$$P\left( \sup_{0 < \ell \leq 2L} |Z_{\ell,0}((i-1)2^{-K}, i2^{-K})| > 4\varepsilon_{K,L} \right) \ll \left( \frac{1}{3^L} + \frac{L^{5+3\delta \ell(2+\delta)}}{2L^\delta/2} \right). \quad (4.31)$$

From (4.29) and (4.31), we then get that for $L$ large enough and any $\kappa \leq 1$,

$$\sum_{K = r(L)+1}^{L} P \left( \sup_{0 < \ell \leq 2L} \Delta_{K,\ell,0} > \sqrt{AC(\beta)}c_K 2^{L(1-\varepsilon)-2} \right) \ll \sum_{K = r(L)+1}^{\lfloor \kappa L \rfloor} 2^K \left( \frac{1}{3^L} + \frac{L^{5+3\delta \ell(2+\delta)}}{2L^\delta/2} \right) + 2^{r-2} L^{2p} \sum_{K = \lceil \kappa L \rceil + 1}^{L} (2^{-K(p-2)/2} + 2^{-(1+\delta)\ell - p}/2 + 2^{-L(p-2)/2+\eta L}) \right).$$

Take $\kappa = \kappa(\varepsilon) = 1 \wedge 2\varepsilon(p+1)/(p-2)$. It follows that (4.27) (and then (4.22)), holds provided that the following constraints on $\varepsilon$ are satisfied

$$\varepsilon < \frac{p-2}{2(p+1)}, \varepsilon(2+\delta + \frac{2(p+1)}{p-2}) < \delta/2, \varepsilon p < \frac{p-2}{2} - \eta, \text{ and } \varepsilon p < \eta(1+\delta - p/2).$$

Let us take

$$\eta = \frac{p-2}{4+2\delta - p} \text{ and } p = 3 \wedge (2+\delta/2).$$

Both the above constraints on $\varepsilon$ and (4.20) are satisfied for $\varepsilon = \delta^2/(2(\delta+2)^2)$. Therefore (4.22) holds, and Theorem 2.1 follows.

**4.1.3 Gaussian approximation**

**Proposition 4.1** For $L \in \mathbb{N}$, let $m(L) \in \mathbb{N}$ and $r(L) \in \mathbb{N}^*$ be such that $m(L) \leq L$ and $4r(L) \leq m(L)$.

Under the assumptions of Theorem 2.1 and the notations of Section 4.1.1, the following inequality holds: there exists a positive constant $C$ not depending on $L$ such that, for any $\ell \in \{1, \ldots, 2^{L-m(L)}\}$,

$$E(d_{r(L)}(U_{L,\ell}, V_{L,\ell})) \leq C 2^{\frac{m(L)+2r(L)}{2(L+1)^2}} L^2.$$

**Proof of Proposition 4.1.** From the stationarity of the sequence $((U_{L,\ell}, V_{L,\ell}))_{\ell = 1, \ldots, 2^{L-m(L)}}$, it suffices to prove the proposition for $\ell = 1$. Let $L \in \mathbb{N}$ and $K \in \{0, \ldots, r(L) - 1\}$. To shorten the notations, let us define the following set of integers

$$\mathcal{E}(L, K) = \{1, \ldots, 2^{r(L)-K} - 1\} \cap (2\mathbb{N} + 1),$$

meaning that if $k \in \mathcal{E}(L, K)$ then $k$ is an odd integer in $[1, 2^{r(L)-K} - 1]$.

For $K \in \{0, \ldots, r(L) - 1\}$ and $k \in \mathcal{E}(L, K)$, define

$$B_{K,k} = \left[ \frac{(k-1)2^K}{2^{r(L)}}, \frac{k2^K}{2^{r(L)}} \right] \text{ and } Z_{L}^{(K,k)} = \sum_{i \in \mathbb{L}_{L,1}} (1_{Y_i \in B_{K,k}} - P_Y(B_{K,k})).$$

The associated column vector $Z_L$ in $\mathbb{R}^{2^{r(L)-1}}$ is then defined by

$$Z_L = \left( (Z_{L}^{(1,k)}, k_i \in \mathcal{E}(L, i))_{i = 0, \ldots, r(L) - 1} \right)'.$$
Notice that for any $j \in \{1, \ldots, 2^{r(L)} - 1\}$,

$$U_{L,1}^{(j)} = \sum_{K=0}^{r(L)-1} \sum_{k \in \mathcal{E}(L, K)} b_{K,k}(j) Z_{L}^{(K,kk)},$$

(4.32)

with $b_{K,k}(j) = 0$ or $1$. This representation is unique in the sense that, for $j$ fixed, there exists only one vector $(b_{K,k}(j), kK \in \mathcal{E}(L, K))_{K=0,\ldots,r(L)-1}$ satisfying (4.32). In addition, for any $K$ in \{0, \ldots, r(L) - 1\}, $\sum_{k \in \mathcal{E}(L, K)} b_{K,k}(j) \leq 1$. Let the column vector $b(j, L)$ and the matrix $P_{L}$ be defined by

$$b(j, L) = \left( (b_{K,k}(j), kK \in \mathcal{E}(L, K))_{K=0,\ldots,r(L)-1} \right)'$$

and $P_{L} = \left( b(1, L), b(2, L), \ldots, b(2^{r(L)} - 1, L) \right)'$.

$P_{L}$ has the following property: it is a square matrix of $\mathbb{R}^{2^{r(L)}-1}$ with determinant equal to 1. Let us denote by $P_{L}^{-1}$ its inverse. With this notation, we then notice that

$$Z_{L} = P_{L}^{-1} U_{L,1}.$$

(4.33)

Let now $a^{2}$ be a positive real and $V = (V^{(1)}, \ldots, V^{(2^{r(L)}-1)})'$ be a random variable with law $\mathcal{N}(0, a^{2}P_{L}P_{L}^{'})$. According to the coupling relation (4.5), we have that

$$\mathbb{E}(d_{r(L)}(U_{L,1}, V_{L,1})) = \mathbb{E}(W_{d_{r(L)}}(P_{U_{L,1}}|\mathcal{F}_{L}, G_{2^{m(L)}\Lambda_{L}}))$$

$$\leq \mathbb{E}(W_{d_{r(L)}}(P_{U_{L,1}}|\mathcal{F}_{L} * P_{V}, G_{2^{m(L)}\Lambda_{L}} * P_{V})) + 2\mathbb{E}(d_{r(L)}(V,0)),$$

(4.34)

where $*$ stands for the usual convolution product. Since $V^{(j)}$ is a centered real Gaussian random variable with variance $v_{j}^{2} = a^{2}\sum_{K=0}^{r(L)-1} \sum_{k \in \mathcal{E}(L, K)} b_{K,k}(j)$, according to the inequality (3.6) in Ledoux and Talagrand (1991), we derive that

$$\mathbb{E}(d_{r(L)}(V,0)) = \mathbb{E}\left( \max_{j \in \{1,\ldots,2^{r(L)-1}\}} |V^{(j)}| \right) \leq \left( 2 + 3(\log(2^{r(L)}) - 1) \right)^{1/2} \max_{j \in \{1,\ldots,2^{r(L)-1}\}} v_{j}.$$

Since $v_{j}^{2} \leq a^{2}r(L) \leq a^{2}L$, we then get that

$$\mathbb{E}(d_{r(L)}(V,0)) \leq 5aL.$$

(4.35)

Let us now give an upper bound for the quantity $\mathbb{E}(W_{d_{r(L)}}(P_{U_{L,1}}|\mathcal{F}_{L} * P_{V}, G_{2^{m(L)}\Lambda_{L}} * P_{V}))$ in (4.34). Let $(N_{i,L})_{i \in \mathbb{Z}}$ be a sequence of independent random variables with normal distribution $\mathcal{N}(0, \Lambda_{L})$. Suppose furthermore that the sequence $(N_{i,L})_{i \in \mathbb{Z}}$ is independent of $\mathcal{F}_{\infty} \lor \sigma(\eta_{i}, i \in \mathbb{Z})$. Denote by $I_{2^{r(L)}-1}$ the identity matrix on $\mathbb{R}^{2^{r(L)}-1}$ and let $N$ be a $\mathcal{N}(0, a^{2}I_{2^{r(L)}-1})$-distributed random variable, independent of $\mathcal{F}_{\infty} \lor \sigma(\eta_{i}, i \in \mathbb{Z}) \lor \sigma(\eta_{i}, i \in \mathbb{Z})$. Set $\tilde{N}_{L} = N_{1,L} + N_{2,L} + \ldots + N_{2^{m(L)}\Lambda_{L}}$. We first notice that

$$\mathbb{E}(W_{d_{r(L)}}(P_{U_{L,1}}|\mathcal{F}_{L} * P_{V}, G_{2^{m(L)}\Lambda_{L}} * P_{V}))$$

$$= \mathbb{E} \sup_{f \in \text{Lip}(d_{r(L)})} \left( \mathbb{E}(f(U_{L,1} + P_{L}N)|\mathcal{F}_{L}) - \mathbb{E}(f(\tilde{N}_{L} + P_{L}N)) \right).$$

(4.36)

Introduce now the following definition:
Definition 4.3 For $x = \left( (x^{(i,k)})_{i=0,\ldots,r(L)-1}, k \in \mathcal{E}(L,i) \right)'$, $y = \left( (y^{(i,k)})_{i=0,\ldots,r(L)-1} \right)'$, two column vectors of $\mathbb{R}^{2r(L)-1}$, let $d^*_r(L)$ be the following distance:

$$d^*_r(L)(x,y) = \sup_{K=0}^{r(L)-1} K \in \mathcal{E}(L,K) \left| x^{(K,k)} - y^{(K,k)} \right|.$$  

Let also $\text{Lip}(d^*_r(L))$ be the set of functions from $\mathbb{R}^{2r(L)-1}$ into $\mathbb{R}$ that are Lipschitz with respect to $d^*_r(L)$; namely, $|f(x) - f(y)| \leq \sum_{K=0}^{r(L)-1} \sup_{K \in \mathcal{E}(L,K)}|x^{(K,k)} - y^{(K,k)}|$. Let $x = (x^{(1)}, \ldots, x^{(2r(L)-1)})'$ and $y = (y^{(1)}, \ldots, y^{(2r(L)-1)})'$ be two column vectors of $\mathbb{R}^{2r(L)-1}$. Let now $u = \mathbf{P}_L^{-1}x$ and $v = \mathbf{P}_L^{-1}y$. The vectors $u$ and $v$ of $\mathbb{R}^{2r(L)-1}$ can be rewritten $u = \left( (u^{(i,k)}, k_i \in \mathcal{E}(L,i))_{i=0,\ldots,r(L)-1} \right)'$ and $v = \left( (v^{(i,k)}, k_i \in \mathcal{E}(L,i))_{i=0,\ldots,r(L)-1} \right)'$. Notice now that if $f \in \text{Lip}(d_r(L))$, then

$$|f(x) - f(y)| \leq d_r(L)(x,y) = \sup_{j \in \{1,\ldots,2^{r(L)-1}\}} |b(j,L)'u - b(j,L)'v|$$

$$\leq \sup_{j \in \{1,\ldots,2^{r(L)-1}\}} \sum_{K=0}^{r(L)-1} \sum_{k \in \mathcal{E}(L,K)} b_{K,k,k}(j)|u^{(K,k,k)} - v^{(K,k,k)}|$$

$$\leq \sup_{j \in \{1,\ldots,2^{r(L)-1}\}} \sum_{K=0}^{r(L)-1} \sum_{k \in \mathcal{E}(L,K)} b_{K,k,k}(j) \sup_{i \in \mathcal{E}(L,K)} |u^{(K,i)} - v^{(K,i)}|.$$  

Since for any $K \in \{0,\ldots,r(L)-1\}$ and any $j \in \{0,\ldots,2^{r(L)-1}\}$, $\sum_{k \in \mathcal{E}(L,K)} b_{K,k,k}(j) \leq 1$, it follows that if $f \in \text{Lip}(d_r(L))$,

$$|f(x) - f(y)| = |f \circ \mathbf{P}_L(u) - f \circ \mathbf{P}_L(v)| \leq \sum_{K=0}^{r(L)-1} \sum_{k \in \mathcal{E}(L,K)} |u^{(K,k)} - v^{(K,k)}| = d^*_r(L)(u,v).$$

Therefore, starting from (4.36) and taking into account (4.33), we get

$$\mathbb{E}(W_{d_r(L)}(P_{U_L} \bowtie \mathcal{F}_{2L} P_{V_L} \bowtie \mathcal{F}_{2L} G_{2^r(L)} \bowtie \mathcal{F}_{2L} P_{V}))$$

$$\leq \mathbb{E} \sup_{f \in \text{Lip}(d^*_r(L))} \left( \mathbb{E}(f(Z_L + N) \bowtie \mathcal{F}_{2L}) - \mathbb{E}(f(P_L^{-1}\tilde{N}_L + N)) \right).$$  

(4.37)

Let $\text{Lip}(d^*_r(L) \bowtie \mathcal{F}_{2L})$ be the set of measurable functions $g : \mathbb{R}^{2r(L)-1} \times \Omega \to \mathbb{R}$ wrt the $\sigma$-fields $\mathcal{B}(\mathbb{R}^{2r(L)-1}) \bowtie \mathcal{F}_{2L}$ and $\mathcal{B}(\mathbb{R})$, such that $g(\cdot,\omega) \in \text{Lip}(d^*_r(L))$ and $g(0,\omega) = 0$ for any $\omega \in \Omega$. For the sake of brevity, we shall write $g(x)$ in place of $g(x,\omega)$. From Point 2 of Theorem 1 in Dedecker, Prieur and Raynaud de Fitte (2006), the following inequality holds:

$$\mathbb{E} \sup_{f \in \text{Lip}(d^*_r(L) \bowtie \mathcal{F}_{2L})} \left( \mathbb{E}(f(Z_L + N) \bowtie \mathcal{F}_{2L}) - \mathbb{E}(f(P_L^{-1}\tilde{N}_L + N)) \right)$$

$$= \sup_{g \in \text{Lip}(d^*_r(L) \bowtie \mathcal{F}_{2L})} \mathbb{E}(g(Z_L + N)) - \mathbb{E}(g(P_L^{-1}\tilde{N}_L + N)).$$  

(4.38)
We shall prove that if $a \in [L, L2^{m(L)}]$, there exists a positive constant $C$ not depending on $(L,a)$, such that
\[
\sup_{g \in \text{Lip}(d^{(2)}(L),F_{2L})} \mathbb{E}(g(Z_L + N)) - \mathbb{E}(g(P_{L}^{-1}\tilde{N}_L + N)) \leq C a^{-3} L^{5/2} 2^{m(L)} + C a^{-1/2} L^{2r(L)+m(L)} + C a^{-2} L^{2r(L)+m(L)} + C a^{-1} L^{2r(L)}. \tag{4.39}
\]
Gathering (4.39), (4.38), (4.37), (4.34) and (4.35), and taking $a = L2^{m(L)+2r(L))/((2+\delta)^3}$, Proposition 4.1 follows.

Let then $\alpha \in [L, L2^{m(L)}]$ and continue the proof by proving (4.39). For any $i \geq 1$, let $Y_{i,L}$ be the column vector defined by $Y_{i,L} = (Y_{i,1}^{(1)} , \ldots , Y_{i,L}^{(2r(L)-1)})'$ where $Y_{i,L}^{(j)} = 1_{Y_{i+2L} \leq s_i - F_Y(s_j)}$. Notice then that
\[
Z_L = \sum_{i=1}^{2^{m(L)}} Z_{i,L} \text{ where } Z_{i,L} = P_{L}^{-1}Y_{i,L}.
\]
Therefore $Z_{i,L} = \left((Z_{i,L}^{(k,k')}, k,k \in (L,K))_{K=0,\ldots , r(L)-1} \right)'$ where $Z_{i,L}^{(k,k)} = 1_{Y_{i+2L} \in B_{K,k}} - P_Y(B_{K,k})$.

**Notation 4.1** Let $\varphi_\alpha$ be the density of $N$ and let for $x = \left((x^{(i,k)}, k \in (L,K))_{i=0,\ldots, r(L)-1} \right)'$,
\[
g \ast \varphi_\alpha(x, \omega) = \int g(x + y, \omega) \varphi_\alpha(y)dy.
\]
For the sake of brevity, we shall write $g \ast \varphi_\alpha(x)$ instead of $g \ast \varphi_\alpha(x, \omega)$ (the partial derivatives will be taken wrt $x$). Let also
\[
S_{0,L} = 0, \text{ and for } j > 0, \ S_{j,L} = \sum_{i=1}^{j} Z_{i,L}.
\]

We now use the Lindeberg method to prove (4.39). We first write that
\[
\begin{align*}
\mathbb{E}(g(Z_L + N) - g(P_{L}^{-1}\tilde{N}_L + N)) \\
= \sum_{i=1}^{2^{m(L)}} \mathbb{E}\left(g(S_{i-1,L} + Z_{i,L} + \sum_{j=i+1}^{2^{m(L)}} P_{L}^{-1}N_{j,L} + N) - g(S_{i-1,L} + P_{L}^{-1}N_{i,L} + \sum_{j=i+1}^{2^{m(L)}} P_{L}^{-1}N_{j,L} + N) \right) \\
\leq \sum_{i=1}^{2^{m(L)}} \sup_{g \in \text{Lip}(d^{(2)}(L),F_{2L})} \mathbb{E}\left(g(S_{i-1,L} + Z_{i,L} + N) - g(S_{i-1,L} + P_{L}^{-1}N_{i,L} + N) \right). \tag{4.40}
\end{align*}
\]
Let us introduce some notations and definitions.

**Definition 4.4** For two positive integers $m$ and $n$, let $\mathcal{M}_{m,n}(\mathbb{R})$ be the set of real matrices with $m$ lines and $n$ columns. The Kronecker product (or Tensor product) of $A = [a_{i,j}] \in \mathcal{M}_{m,n}(\mathbb{R})$ and $B = [b_{i,j}] \in \mathcal{M}_{p,q}(\mathbb{R})$ is denoted by $A \otimes B$ and is defined to be the block matrix
\[
A \otimes B = \begin{pmatrix}
a_{1,1}B & \cdots & a_{1,n}B \\
\vdots & \ddots & \vdots \\
a_{m,1}B & \cdots & a_{m,n}B
\end{pmatrix} \in \mathcal{M}_{mp,nq}(\mathbb{R}).
\]

For any positive integer $k$, the $k$-th Kronecker power $A \otimes^k$ is defined inductively by: $A \otimes^1 = A$ and $A \otimes^k = A \otimes A \otimes^{(k-1)}$. 

17
If $\nabla$ denotes the differentiation operator given by $\nabla = \left( \frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_m} \right)'$ acting on the differentiable functions $f: \mathbb{R}^m \to \mathbb{R}$, we define

$$\nabla \otimes \nabla = \left( \frac{\partial}{\partial x_1} \circ \nabla, \ldots, \frac{\partial}{\partial x_m} \circ \nabla \right)' ,$$

and $\nabla^\otimes k$ by $\nabla^\otimes 1 = \nabla$ and $\nabla^\otimes k = \nabla \otimes \nabla^\otimes (k-1)$. If $f: \mathbb{R}^m \to \mathbb{R}$ is $k$-times differentiable, for any $x \in \mathbb{R}^m$, let $D^k f(x) = \nabla^\otimes k f(x)$, and for any vector $\tilde{A}$ of $\mathbb{R}^m$, we define $D^k f(x). \tilde{A}^\otimes k$ as the usual scalar product in $\mathbb{R}^m$ between $D^k f(x)$ and $A^\otimes k$.

For any $i \in \{1, \ldots, 2^m(L)\}$, let $G_{i, L} = \mathbf{P}^{-1}_{L} N_{i, L}$,

$$\Delta_{1, i, L}(g) = g * \varphi_a(S_{i-1, L} + Z_{i, L}) - g * \varphi_a(S_{i-1, L}) - \frac{1}{2} D^2 g * \varphi_a(S_{i-1, L}). G_{i, L}^2,$$

and

$$\Delta_{2, i, L}(g) = g * \varphi_a(S_{i-1, L} + G_{i, L}) - g * \varphi_a(S_{i-1, L}) - \frac{1}{2} D^2 g * \varphi_a(S_{i-1, L}). G_{i, L}^2.$$

With this notation,

$$E\left(g(S_{i-1, L} + Z_{i, L} + N) - g(S_{i-1, L} + \mathbf{P}^{-1}_{L} N_{i, L} + N)\right) = E(\Delta_{1, i, L}(g)) - E(\Delta_{2, i, L}(g)). \quad (4.41)$$

By Taylor's integral formula and noticing that $E(G_{i, L}^3) = 0$, we get

$$\left|E(\Delta_{2, i, L}(g))\right| \leq \frac{1}{6} E \int_0^1 D^4 g * \varphi_a(S_{i-1, L} + t G_{i, L}). G_{i, L}^4 dt .$$

Applying Lemma 5.5, we then derive that

$$\left|E(\Delta_{2, i, L}(g))\right| \ll a^{-3} E\left( \left( \sum_{K=0}^{r(L)-1} \sup_{K \in \mathcal{E}(L, K)} |G_{1, L}^{(K, k)}| \right) \left( \sum_{K=0}^{r(L)-1} \sum_{k_K \in \mathcal{E}(L, K)} (G_{1, L}^{(K, k)})^2 \right)^{3/2} \right)$$

$$\ll a^{-3} \left( E\left( \sum_{K=0}^{r(L)-1} \sup_{K \in \mathcal{E}(L, K)} |G_{1, L}^{(K, k)}| \right)^4 \right)^{1/4} \left( E\left( \sum_{K=0}^{r(L)-1} \sum_{k_K \in \mathcal{E}(L, K)} (G_{1, L}^{(K, k)})^2 \right)^3 \right)^{3/4} . \quad (4.42)$$

Notice that

$$\sum_{K=0}^{r(L)-1} \sup_{k \in \mathcal{E}(L, K)} |G_{1, L}^{(K, k)}| \leq \sum_{K=0}^{r(L)-1} \left( \sum_{k_K \in \mathcal{E}(L, K)} (G_{1, L}^{(K, k)})^2 \right)^{1/2} \leq \sqrt{r(L)} \left( \sum_{K=0}^{r(L)-1} \sum_{k_K \in \mathcal{E}(L, K)} (G_{1, L}^{(K, k)})^2 \right)^{1/2} . \quad (4.43)$$

Moreover

$$E\left( \sum_{K=0}^{r(L)-1} \sum_{k_K \in \mathcal{E}(L, K)} (G_{1, L}^{(K, k)})^2 \right)^2 \leq \left( \sum_{K=0}^{r(L)-1} \sum_{k_K \in \mathcal{E}(L, K)} (E(G_{1, L}^{(K, k)})^4)^{1/2} \right)^2$$

$$\leq 3 \left( \sum_{K=0}^{r(L)-1} \sum_{k_K \in \mathcal{E}(L, K)} E((G_{1, L}^{(K, k)})^2) \right)^2 .$$

and

$$\sum_{k \in \mathcal{E}(L, K)} E((G_{1, L}^{(K, k)})^2) = \sum_{k \in \mathcal{E}(L, K)} \left( \text{Var}(Z_{1, L}^{(K, k)}) + 2 \sum_{i>0} \text{Cov}(Z_{1, L}^{(K, k)}, Z_{i+1, L}^{(K, k)}) \right) .$$
Arguing as to get (4.30), we then obtain that
\[
\sum_{k \in \mathcal{E}(L,K)} \mathbb{E}(G_{1,L}^{(K,k)})^2 \leq C(\beta) \sum_{k \in \mathcal{E}(L,K)} 2^{K-r(L)} \leq C(\beta).
\]
From the above computations, it follows that
\[
\mathbb{E} \left( \sum_{K=0}^{r(L)-1} \sum_{k \in \mathcal{E}(L,K)} (G_{1,L}^{(K,k)})^2 \right) \leq 3(C(\beta)r(L))^2.
\]
(4.44)
Therefore, starting from (4.42), taking into account (4.43), (4.44) and the fact that \(r(L) \leq L\), we then derive that
\[
\mathbb{E}(\Delta_{2,i,L}(g)) \ll a^{-3}L^{5/2}.
\]
(4.45)
Let now
\[
R_{1,i,L}(g) = g \ast \varphi_a(S_{i-1,L} + Z_{i,L}) - g \ast \varphi_a(S_{i-1,L}) - Dg \ast \varphi_a(S_{i-1,L}) \cdot Z_{i,L} - \frac{1}{2} D^2 g \ast \varphi_a(S_{i-1,L}) \cdot Z_{i,L}^2,
\]
and
\[
D_{1,i,L}(g) = Dg \ast \varphi_a(S_{i-1,L}) \cdot Z_{i,L} + \frac{1}{2} D^2 (g \ast \varphi_a)(S_{i-1,L}) \cdot Z_{i,L}^2 - \frac{1}{2} D^2 g \ast \varphi_a(S_{i-1,L}) \cdot \mathbb{E}(G_{1,L}^2).
\]
With this notation,
\[
\mathbb{E}(\Delta_{1,i,L}(g)) = \mathbb{E}(R_{1,i,L}(g)) + \mathbb{E}(D_{1,i,L}(g)).
\]
(4.46)
By Taylor’s integral formula,
\[
|\mathbb{E}(R_{1,i,L}(g))| \leq \left| \mathbb{E} \int_0^1 \left( 1 - t \right)^2 \frac{1}{2} D^3 g \ast \varphi_a(S_{i-1,L} + tZ_{i,L}) \cdot Z_{i,L}^3 \right|.
\]
Applying Lemma 5.5 and using the fact that \(\sup_{k \in \mathcal{E}(L,K)} |Z_{i,L}^{(K,k)}| \leq 2\) and \(\sum_{k \in \mathcal{E}(L,K)} (Z_{i,L}^{(K,k)})^2 \leq 2\), we get that
\[
|\mathbb{E}(R_{1,i,L}(g))| \ll a^{-2}(r(L))^2 \ll a^{-2}L^2.
\]
(4.47)
Let
\[
\Delta(i,j)(g) = D^2 g \ast \varphi_a(S_{i-1,j}) - D^2 g \ast \varphi_a(S_{i-1,j-1,L}),
\]
and
\[
u_L = [aL^{-1}].
\]
(4.49)
Clearly with the notation \(X^{(0)} = X - \mathbb{E}(X)\),
\[
D^2 g \ast \varphi_a(S_{i-1,L}) \cdot (Z_{i,L}^{(0)}) \ll \sum_{j=1}^{(u_L \wedge i) - 1} \Delta(i,j)(g) \cdot (Z_{i,L}^{(0)}),
\]
(4.50)
For any \(j \leq (u_L \wedge i) - 1\), write that \(\mathbb{E}(\Delta(i,j)(g) \cdot (Z_{i,L}^{(0)}) = \mathbb{E}(\Delta(i,j)(g) \cdot \mathbb{E}_{i,j+2L}(Z_{i,L}^{(0)})\right),\) and notice that, by Lemma 5.6,
\[
\mathbb{E}(\Delta(i,j)(g) \cdot \mathbb{E}_{i,j+2L}(Z_{i,L}^{(0)}) \ll \sup_{t \in [0,1]} \left| \mathbb{E}(D^3 g \ast \varphi_a(S_{i-1,j} + tZ_{i,j}) \cdot (Z_{i,j} \otimes \mathbb{E}_{i,j+2L}(Z_{i,L}^{(0)})\right)|
\ll a^{-2} \sum_{K_1,K_3} \sum_{K_2,K_3} \sum_{K_3,K_5} \mathbb{E}(Z_{i-1,j,L}^{(K_1,K_3)} \cdot \mathbb{E}_{i,j+2L}(Z_{i,L}^{(K_2,K_5)} \otimes Z_{i,L}^{(K_3,K_5)} - \mathbb{E}(Z_{i,L}^{(K_2,K_5)} \otimes Z_{i,L}^{(K_3,K_5)})),
\]
(19)
where for any $i \in \{1, 2, 3\}$, $K_i \in \{0, \ldots, r(L) - 1\}$ and $k_{K_i} \in \mathcal{E}(L, K_i)$. Applying Lemma 5.1, we infer that
\[ |\mathbb{E}_{i=1}^{r(L)-1} Z_{i, L}^{K_i, k_{K_i}} - \mathbb{E}(Z_{i, L}^{K_i, k_{K_i}})| \leq 4b_1(F_{i+j+2^L}, i + 2^L). \]
Therefore since \( \sum_{K_i=0}^{r(L)-1} \sum_{k_{K_i} \in \mathcal{E}(L, K_i)} |Z_{i, L}^{K_i, k_{K_i}}| \leq 2r(L) \) and \( \mathbb{E}(b_1(F_{i+j+2^L}, i + 2^L)) \leq \beta_1 \chi(j) \), we derive that
\[ \mathbb{E}(\Delta(i, j)(g)(Z_{i, L}^{(0)})) \ll a^{-2} r(L) 2^{2r(L)} \beta_1 \chi(j). \]
On the other hand, by using Lemma 5.6, we infer that
\[ \mathbb{E}(D^2 g \circ \phi_a(S_{i-(uL \wedge i)}), Z_{i, L}^{(0)}) = \mathbb{E}(D^2 g \circ \phi_a(S_{i-(uL \wedge i)}), Z_{i, L}^{(0)}) \ll a^{-1} \sum_{K_1, K_2} \sum_{k_{K_1}, k_{K_2}} \mathbb{E}(\Delta_{i-(uL \wedge i)}(Z_{i, L}^{K_1, k_{K_1}} Z_{i, L}^{K_2, k_{K_2}} - \mathbb{E}(Z_{i, L}^{K_1, k_{K_1}} Z_{i, L}^{K_2, k_{K_2}}))). \]
Using the same arguments as to get (4.51), we obtain that
\[ \mathbb{E}(D^2 g \circ \phi_a(S_{i-(uL \wedge i)}), Z_{i, L}^{(0)}) \ll a^{-1} 2^{2r(L)} \beta_1 \chi(uL \wedge i). \]
Starting from (4.50) and taking into account (4.51), (4.52), the choice of $u_L$ and the condition on the $\beta$-dependence coefficients, we then derive that
\[ \sum_{i=1}^{2m(L)} \mathbb{E}(D^2 g \circ \phi_a(S_{i-1, L}), Z_{i, L}^{(0)}) \ll 2^{2r(L)} a^{-1} \left( \frac{2m(L) L^{1+\delta}}{a^{1+\delta}} + 2m(L) \frac{L}{a} \right). \]
To give now an estimate of the expectation of $Dg \circ \phi_a(S_{i-1, L}). Z_{i, L}$, we write
\[ Dg \circ \phi_a(S_{i-1, L}) = Dg \circ \phi_a(0) + \sum_{j=1}^{i-1} (Dg \circ \phi_a(S_{i-j, L}) - Dg \circ \phi_a(S_{i-j-1, L})). \]
Hence
\[ \mathbb{E}(Dg \circ \phi_a(S_{i-1, L}). Z_{i, L}) = \mathbb{E}(Dg \circ \phi_a(0). Z_{i, L}) + \sum_{j=1}^{i-1} \mathbb{E}((Dg \circ \phi_a(S_{i-j, L}) - Dg \circ \phi_a(S_{i-j-1, L})). Z_{i, L}). \]
Applying Lemma 5.1,
\[ |\mathbb{E}(Dg \circ \phi_a(0). Z_{i, L})| = |\mathbb{E}(Dg \circ \phi_a(0) E_{2^L}(Z_{i, L}))| \leq \mathbb{E} \left( \sum_{K=0}^{r(L)-1} \sum_{k_{K} \in \mathcal{E}(L, K)} \left| \frac{\partial g \circ \phi_a}{\partial x(K, k_{K})}(0) \right| b_1(F_{i+2^L}, i + 2^L) \right). \]
Notice now that by the inequality (5.3), for any $K$ in $\{0, \ldots, r(L) - 1\}$, the random variable
\[ \sum_{k \in \mathcal{E}(L, K)} \left| \frac{\partial g \circ \phi_a}{\partial x(K, k)}(0) \right| \]
is a $\mathcal{F}_{2^L}$-measurable random variable with infinite norm less than one. Therefore
\[ |\mathbb{E}(Dg \circ \phi_a(0). Z_{i, L})| \ll r(L) \beta_1 \chi(i). \]
We give now an estimate of \( \sum_{j=1}^{i-1} \mathbb{E}( (Dg \ast \varphi_a(S_{i-j,L}) - Dg \ast \varphi_a(S_{i-j-1,L})),Z_{i,L}) \). By Lemma 5.6 and Lemma 5.1, for any \( i \geq j + 1 \),

\[
|\mathbb{E}( (Dg \ast \varphi_a(S_{i-j,L}) - Dg \ast \varphi_a(S_{i-j-1,L})),Z_{i,L})| = |\mathbb{E}( (Dg \ast \varphi_a(S_{i-j,L}) - Dg \ast \varphi_a(S_{i-j-1,L})),\mathbb{E}_{i-j+2L}(Z_{i,L}))|
\leq \sup_{t \in [0,1]} \mathbb{E}( (D^2g \ast \varphi_a(S_{i-j-1,L} + tZ_{i,L}),(Z_{i-j,L} \otimes \mathbb{E}_{i-j+2L}(Z_{i,L})))
\leq a^{-1} \sum_{K_1=0}^{r(L)-1} \sum_{K_2=0}^{r(L)-1} \sum_{K_3=0}^{r(L)-1} \mathbb{E}( (Z_{i-j,L}^{K_1,K_2} b_1(F_{i-j+2L},i+2L))).
\]

We then infer that for any \( i \geq j + 1 \),

\[
|\mathbb{E}( (Dg \ast \varphi_a(S_{i-j,L}) - Dg \ast \varphi_a(S_{i-j-1,L})),Z_{i,L})| \ll a^{-1} r(L) 2^{r(L)} \beta_{1,X}(j). \tag{4.56}
\]

From now on, we assume that \( j < i \wedge u_L \). Notice that

\[
(Dg \ast \varphi_a(S_{i-j,L}) - Dg \ast \varphi_a(S_{i-j-1,L})),Z_{i,L} - D^2g \ast \varphi_a(S_{i-j-1,L}),(Z_{i-j,L} \otimes Z_{i,L}) = \int_0^1 (1-t) D^3g \ast \varphi_a(S_{i-j-1,L} + tZ_{i,j,L}),(Z_{i-j,L} \otimes Z_{i,L}) dt.
\]

By using Lemma 5.6 and Lemma 5.1, we infer that

\[
|\mathbb{E}( \int_0^1 (1-t) D^3g \ast \varphi_a(S_{i-j-1,L} + tZ_{i,j,L}),(Z_{i-j,L} \otimes Z_{i,L}) dt)| \ll a^{-2} \sum_{K_1=0}^{r(L)-1} \sum_{K_2=0}^{r(L)-1} \sum_{K_3=0}^{r(L)-1} \mathbb{E}( (Z_{i-j,L}^{K_1,K_2,k_{K_3}} b_1(F_{i-j+2L},i+2L))).
\]

Therefore,

\[
|\mathbb{E}( \int_0^1 (1-t) D^3g \ast \varphi_a(S_{i-j-1,L} + tZ_{i,j,L}),(Z_{i-j,L} \otimes Z_{i,L}) dt)| \ll a^{-2} r(L) 2^{r(L)} \beta_{1,X}(j). \tag{4.57}
\]

In order to estimate the term \( \mathbb{E}( (D^2g \ast \varphi_a(S_{i-j-1,L}),(Z_{i-j,L} \otimes Z_{i,L})) \), we use the following decomposition:

\[
D^2g \ast \varphi_a(S_{i-j-1,L}) = \sum_{l=1}^{(j-1) \wedge (i-j-1)} (D^2g \ast \varphi_a(S_{i-j-1,L}) - D^2g \ast \varphi_a(S_{i-j-l-1,L}))) + D^2g \ast \varphi_a(S_{(i-2)\wedge 0,L}).
\]

For any \( l \in \{1, \cdots, (j-1) \wedge (i-j-1)\} \), using the same arguments as to get (4.57), we obtain that

\[
|\mathbb{E}( (D^2g \ast \varphi_a(S_{i-j-1,L}) - D^2g \ast \varphi_a(S_{i-j-l-1,L})),(Z_{i-j,L} \otimes Z_{i,L}))| \ll a^{-2} r(L) 2^{r(L)} \beta_{1,X}(j). \tag{4.58}
\]

As a second step, we bound up \( |\mathbb{E}( (D^2g \ast \varphi_a(S_{(i-2)\wedge 0,L}),(Z_{i-j,L} \otimes Z_{i,L}))| \). Assume first that \( j \leq \lfloor i/2 \rfloor \). Clearly, using the notation (4.48),

\[
D^2g \ast \varphi_a(S_{i-j,L}) = \sum_{l=j}^{(u_L-1) \wedge (i-j-1)} \Delta(i,l+j)(g) + D^2g \ast \varphi_a(S_{(i-j-u_L)\wedge 0,L}).
\]

21
Now for any \( l \in \{ j, \ldots, (u_L - 1) \wedge (i - j - 1) \} \), by using Lemma 5.6 we get that

\[
|E(\Delta(i, l + j) \cdot (Z_{i-j,L} \otimes Z_{i,L})^{(0)})| 
\ll a^{-2} \sum_{K_1,kK_1} \sum_{K_2,kK_2} \sum_{K_3,kK_3} E[Z_{i-j-(l+1),L}^{K_1,kK_1} E_{i-j-(l+1)2^L}(Z_{i-j,L}^{K_2,kK_2} Z_{i,L}^{K_3,kK_3} - E(Z_{i-j,L}^{K_2,kK_2} Z_{i,L}^{K_3,kK_3}))].
\]

Applying Lemma 5.1, we infer that

\[
|E_{i-j-l+2L}(Z_{i-j,L}^{K_2,kK_2} Z_{i,L}^{K_3,kK_3} - E(Z_{i-j,L}^{K_2,kK_2} Z_{i,L}^{K_3,kK_3}))| \leq 4b_2(F_{i-j-l+2l}, i - j + 2^L, i + 2^L).
\]

Therefore

\[
|E(\Delta(i, l + j) \cdot (Z_{i-j,L} \otimes Z_{i,L})^{(0)})| \ll a^{-2} r(L) 2^{2r(L)} \beta_2 \cdot X(l).
\]  

(4.59)

If \( j \leq i - u_L \), with similar arguments,

\[
|E(D^2 g * \varphi_a(S_{i-j-u_L,L}),(Z_{i-j,L} \otimes Z_{i,L})^{(0)})| \ll a^{-1} 2^{2r(L)} \beta_2 \cdot X(u_L).
\]  

(4.60)

Now if \( j > i - u_L \), we infer that

\[
|E(D^2 g * \varphi_a(0),(Z_{i-j,L} \otimes Z_{i,L})^{(0)})| \ll a^{-1} 2^{2r(L)} \beta_2 \cdot X([i/2]),
\]  

(4.61)

by using also the fact that, since \( j \leq [i/2] \), \( \beta_2 \cdot X(i-j) \leq \beta_2 \cdot X([i/2]) \). Assume now that \( j \geq [i/2] + 1 \). For any \( j \leq i \), we get

\[
|E(D^2 g * \varphi_a(0),(Z_{i-j,L} \otimes Z_{i,L})| \ll a^{-1} r(L) 2^{r(L)} \beta_1 \cdot X([i/2]).
\]  

(4.62)

Starting from (4.54), adding the inequalities (4.55)-(4.62) and summing on \( j \) and \( l \), we then obtain:

\[
|E(Dg * \varphi_a(S_{i-1,L}) \cdot Z_{i,L}) - \sum_{j=1}^{u_L-1} E(D^2 g * \varphi_a(S_{i-2j,L})) \cdot E(Z_{i-j,L} \otimes Z_{i,L}) \cdot 1_{j \leq [i/2]}| 
\ll r(L) \beta_1 \cdot X(i) + a^{-1} L 2^{r(L)} \sum_{j=u_L}^i \beta_1 \cdot X(j) + a^{-1} 2^{2r(L)} u_L \beta_2 \cdot X(u_L)
\]

\[
+ a^{-1} 2^{2r(L)} u_L \beta_2 \cdot X([i/2]) + a^{-1} 2^{2r(L)} u_L \sum_{j=1}^{u_L} j \beta_2 \cdot X(j).
\]

Next summing on \( i \) and taking into account the condition on the \( \beta \)-dependence coefficients and the choice of \( u_L \), we get that

\[
\sum_{i=1}^{2^m(L)} |E(Dg * \varphi_a(S_{i-1,L}) \cdot Z_{i,L}) - \sum_{j=1}^{u_L-1} E(D^2 g * \varphi_a(S_{i-2j,L})) \cdot E(Z_{i-j,L} \otimes Z_{i,L}) \cdot 1_{j \leq [i/2]}| 
\ll L^{-1} 2^{2r(L)} + a^{-1 - \delta} L^{k-2r(L)+m(L)} + a^{-2} L^{2r(L)+m(L)}.
\]  

(4.63)

It remains to bound up

\[
A_i := \left| \sum_{j=1}^{u_L-1} E(D^2 g * \varphi_a(S_{i-2j})) \cdot E(Z_{i-j,L} \otimes Z_{i,L}) \cdot 1_{j \leq [i/2]} - \sum_{j=1}^{\infty} E(D^2 g * \varphi_a(S_{i-1})) \cdot E(Z_{i-j,L} \otimes Z_{i,L}) \right|.
\]

22
We first notice that by Lemma 5.6, for any positive integer \( j \),
\[
|\mathbb{E}(D^2 g \ast \varphi (S_{i-1})) \mathbb{E}(Z_{i-j,L} \otimes Z_{i,L})| \ll a^{-1} \sum_{K_i=0}^{r(L)-1} \sum_{K_j=0}^{r(L)-1} \sum_{K_k=0}^{r(L)-1} \sum_{K_{l1}=0}^{r(L)-1} \sum_{K_{l2}=0}^{r(L)-1} \mathbb{E}(Z_{i-j,L}^{K_1,kK_1} \mathbb{E}_{i-j+2L}(Z_{i,L}^{K_2,kK_2})).
\]
Therefore,
\[
|\mathbb{E}(D^2 g \ast \varphi (S_{i-1})) \mathbb{E}(Z_{i-j,L} \otimes Z_{i,L})| \ll a^{-1} r(L) 2^{r(L)} \beta_{1,X}(j). \tag{4.64}
\]
On the other hand, applying Lemma 5.6, we obtain for any \( i \geq 2 \) and any \( j \in \{1, \ldots, [i/2]\} \),
\[
|\mathbb{E}((D^2 g \ast \varphi (S_{i-1}) - D^2 g \ast \varphi (S_{i-2j})) \mathbb{E}(Z_{i-j,L} \otimes Z_{i,L}))| \ll a^{-2} \sum_{K_i=0}^{r(L)-1} \sum_{K_j=0}^{r(L)-1} \sum_{K_k=0}^{r(L)-1} \sum_{K_{l1}=0}^{r(L)-1} \sum_{K_{l2}=0}^{r(L)-1} \sum_{K_{l3}=0}^{2^{j-1}} \mathbb{E}(Z_{i-2L}^{K_1,kK_1}) \mathbb{E}(Z_{i-j,L}^{K_2,kK_2} \mathbb{E}_{i-j+2L}(Z_{i,L}^{K_3,kK_3})),
\]
which implies that
\[
\sum_{j=1}^{u_L} |\mathbb{E}((D^2 g \ast \varphi (S_{i-1}) - D^2 g \ast \varphi (S_{i-2j})) \mathbb{E}(Z_{i-j,L} \otimes Z_{i,L})[1_{j \leq [i/2]}] \ll a^{-2} (r(L))^2 2^{r(L)} \sum_{j=1}^{u_L} j \beta_{1,X}(j). \tag{4.65}
\]
Therefore (4.64) together with (4.65), the choice of \( u_L \) and the condition on the \( \beta \)-dependence coefficients entail that
\[
\sum_{i=1}^{2^{m(L)}} A_i \ll a^{-1} L^2 2^{r(L)} + a^{-2} L^3 2^{r(L)+m(L)} + a^{-1-\delta} L^{1+\delta} 2^{r(L)+m(L)}. \tag{4.66}
\]
Taking into account (4.40)-(4.47), (4.53), (4.63) and (4.66), the bound (4.39) follows. \( \diamond \)

4.2 Proof of Theorem 3.1

Let \((X_i)_{i \in \mathbb{Z}}\) be a stationary Markov chain with transition kernel \( Q \) defined in (3.1). Notice that for all \((s, s') \in [0, 1]^2\),
\[
\nu(f_s^{(0)} \cdot f_{s'}^{(0)} \circ T^k) = \text{Cov}(1_{X_k \leq s}, 1_{X_0 \leq s'}).
\]
Since \( \beta_{2,X}(k) \) satisfies (3.2), according to the proof of Item 1 of Theorem 2.1, it follows that Item 1 of Theorem 3.1 holds true.

As at the beginning of the proof of Theorem 2.1, we start by considering the probability \( P_\nu^s \) whose density with respect to \( \nu \) is given by (4.2). Let \( F_\nu^s \) be the distribution function of \( P_\nu^s \) (\( F_\nu^s \) is continuous since \( \nu \) is absolutely continuous with respect to the Lebesgue measure). Let now \( T_i = F_\nu^s(T^i) \) and \( Y_i = F_\nu^s(X_i) \). Let \( F_Y \) be the distribution function of \( Y_0 \). Clearly \( R_T(\cdot, \cdot) = R_T(F_\nu^s(\cdot), \cdot) \) almost surely, where
\[
R_T(s, t) = \sum_{1 \leq k \leq t} (1_{T_k \leq s} - F_Y(s)), \ s \in [0, 1], \ t \in \mathbb{R}^+.
\]
Theorem 3.1 will then follow if we can prove that there exists a two-parameter Gaussian process \( K_T^s \) with covariance function \( \Gamma_T^s \) given by \( \Gamma_T^s(s, s', t, t') = \min(t, t') \Lambda_T(s, s') \) where
\[
\Lambda_T(s, s') = \sum_{k \geq 0} \nu(f_s^{(0)} \cdot f_{s'}^{(0)} \circ F_\nu^s(T^k)) + \sum_{k \geq 0} \nu(f_s^{(0)} \cdot f_{s'}^{(0)} \circ F_\nu^s(T^k)). \tag{4.67}
\]
Let us construct the Gaussian random variables \( \{V_L,\ell \} \) as in Section 4.1.1. Notice that since the covariance function \( \Lambda_{\hat{T}} \) is the same as the covariance function \( \Lambda_T \) defined by (4.4), for any measurable function \( f \), \( \mathbb{E}(f(V_{L,1}^*)) = \mathbb{E}(f(V_{L,2L-m(L)}^*)) \). Therefore starting from (4.68) and taking into account (4.70) together with (4.5), we get that

\[
\mathbb{E}(d_{T(L)}(U_{L,1}^*,V_{L,1}^*)) = \sup_{f \in \text{Lip}(d_{T(L)})} \left( \mathbb{E}(f(U_{L,1}^*))|F| - \mathbb{E}(f(V_{L,1}^*))|F| \right).
\]

Let us construct the Gaussian random variables \( V_{L,\ell}^* \) associated to the \( U_{L,\ell} \) as in Section 4.1.1. Notice that since the covariance function \( \Lambda_{\hat{T}} \) is the same as the covariance function \( \Lambda_T \) defined by (4.4), for any measurable function \( f \), \( \mathbb{E}(f(V_{L,1}^*)) = \mathbb{E}(f(V_{L,2L-m(L)}^*)) \). Therefore starting from (4.68) and taking into account (4.70) together with (4.5), we get that

\[
\mathbb{E}(d_{T(L)}(U_{L,1}^*,V_{L,1}^*)) = \sup_{f \in \text{Lip}(d_{T(L)})} \left( \mathbb{E}(f(U_{L,1}^*))|\mathcal{F}_{2L-2L-m(L)}| - \mathbb{E}(f(V_{L,1}^*))|\mathcal{F}_{2L-2L-m(L)}| \right).
\]
Setting \( \Pi_{r(L)}(s) = 2^{-r(L)}|s2^{r(L)}| \) and mimicking the notations of Section 4.1.2, let now
\[
D^*_L,1 = \sup_{s \in [0,1]} \left| R^*_T(s, \ell(L)) - \left( R^*_T(s, 2^L) - R^*_T(\Pi_{r(L)}(s), 2^L) \right) \right|
\]
\[
B^*_{L,3} = \sup_{j \in \{1, \ldots, 2^{m(L)} - 1\}} \sup_{k \in [L, k]} \left| D^*_T(s_j, \ell) - D^*_T(s_j, 2^L + (k - 1)2^{m(L)}) \right|
\]
and let \( D^*_{L,1} \) and \( B^*_{L,3} \) be the same quantities with \( R_T \) replacing \( R^*_T \). Using once again that, on \(([0,1], \nu)\), the random variable \( (T^{2^k+1}, T^{2^k+2}, \ldots, T^{2^k+1}) \) is distributed as \( (X_{2^k+1}, X_{2^k+1-1}, \ldots, X_{2^{k+1}}) \), we infer that for any positive \( \lambda \),
\[
\mathbb{P}(D^*_{L,1} \geq \lambda) \leq \mathbb{P}(2D^*_{L,1} \geq \lambda) \quad \text{and} \quad \mathbb{P}(B^*_{L,3} \geq \lambda) \leq \mathbb{P}(2B^*_{L,3} \geq \lambda).
\] (4.72)
Proceeding as in Section 4.1.2 of the proof of Theorem 2.1, using the fact that the covariance function \( \Gamma_T \) is the same as the covariance function \( \Gamma_Y \) defined by (4.4) (so that all the quantities involving only the Kiefer process \( K^*_T \) can be computed as in the Section 4.1.2) and taking into account (4.71), (4.72), and the fact that the Markov chain \( (X_i)_{i \in \mathbb{Z}} \) satisfies the assumptions of Theorem 2.1, Theorem 3.1 follows. \( \diamond \)

5 Appendix

5.1 Properties of the random variables \( Y_i \)

For the next lemma, we keep the same notations as that of Definition 2.1 and of the beginning of Section 4.1. Recall that the random variables \( Y_i \) have been defined in (4.3).

**Lemma 5.1** The following assertions hold

1. The image measure of \( \mathbb{P}_0^* \) by the variable \( Y_0 \) is the uniform distribution over \([0,1]\).

2. The equality \( F_{P, \beta}^{-1}(Y_i) = X_i \) holds \( \mathbb{P} \)-almost surely. Moreover, \( \mathbb{P} \)-almost surely,
\[
b(X_{0, k}) \geq \sup_{t \in \mathbb{R}} |P_{Y_0}|X_0(f_t) - P_Y(f_t)|,
\]
\[
b_1(\mathcal{F}_t, k) \geq \sup_{t \in \mathbb{R}} |P_{Y_0}|\mathcal{F}_t(f_t) - P_Y(f_t)|,
\]
\[
b_2(\mathcal{F}_t, i, j) \geq \sup_{(s, t) \in \mathbb{R}^2} |P_{Y_0}|(\mathcal{F}_t(f_t^{(s)} \otimes f_t^{(0)}) - P_Y(f_t^{(0)} \otimes f_t^{(0)})|.
\]

**Proof of Lemma 5.1.** As in Definition 2.1, define
\[
b(X_{i, k}) = \sup_{t \in \mathbb{R}} |P_{X_0}|X_i(f_t) - P(f_t)|.
\]
On \( \Omega \), we introduce the probability \( \mathbb{P}_1^* \) whose density with respect to \( \mathbb{P} \) is
\[
C(\beta)^{-1}(1 + 4 \sum_{k=i+1}^{\infty} b(X_{i, k}) \text{ with } C(\beta) = 1 + 4 \sum_{k=1}^{\infty} \beta(\sigma(X_0), X_k).
\] (5.1)
By stationarity of \( (X_i)_{i \in \mathbb{Z}} \), the image measure of \( \mathbb{P}_1^* \) by \( X_1 \) is again \( P^* \). It follows from Lemma F.1 page 161 in Rio (2000) that the image measure of \( \mathbb{P}_1^* \) by the variable \( Y_i \) is the uniform distribution over \([0,1]\) (proving Item 1), and that the equality \( F_{P, \beta}^{-1}(Y_i) = X_i \) holds \( \mathbb{P}_1^* \)-almost surely. Since the
probabilities $\mathbb{P}$ and $\mathbb{P}_i$ are equivalent, it follows that the equality $F_{i,P}^{-1}(Y_i) = X_i$ holds $\mathbb{P}$-almost surely, proving the first point of Item 2.

Now, note that $Y_i = g(X_i, \eta_i)$, where the function $x \to g(x, u)$ is non decreasing for any $u \in [0,1]$. Since $(X_0, X_k)$ is independent of $\eta_k$,

$$|P_{Y_k|X_0}(f_i) - P_Y(f_i)| = \left| \int_0^1 \{E(f_i(g(X_k, u))|X_0) - E(f_i(g(X_k, u)))\} du \right| \text{ almost surely.}$$

The function $x \to g(x, u)$ being non decreasing, we infer that

$$|E(f_i(g(X_k, u))|X_0) - E(f_i(g(X_k, u)))| \leq b(X_0, k) \text{ almost surely,}$$
in such a way that

$$|P_{Y_k|X_0}(f_i) - P_Y(f_i)| \leq b(X_0, k) \text{ almost surely.}$$

The two last inequalities of Item 2 may be proved in the same way. $\diamond$

### 5.2 Some upper bounds for partial derivatives

Let $x$ and $y$ be two column vectors of $\mathbb{R}^{2^{(L-1)}}$ with coordinates

$$x = \left( (x^{(i,k)}, k_i \in E(L, i))_{i=0,\ldots,r(L)-1} \right)' \text{ and } y = \left( (y^{(i,k)}, k_i \in E(L, i))_{i=0,\ldots,r(L)-1} \right)'$$

where $E(L, i) = \{1, \ldots, 2^{r(L)-i} - 1\} \cap (2\mathbb{N} + 1)$. Let $f \in \text{Lip}(d^*_r(L))$, meaning that

$$|f(x) - f(y)| \leq \sum_{K=0}^{r(L)-1} \sup_{k \in E(L,K)} |x^{(K,k)} - y^{(K,k)}|$$

(the distance $d^*_r(L)$ is defined in Definition 4.3). Let $a > 0$ and $\varphi_a$ be the density of a centered Gaussian law of $\mathbb{R}^{2^{(L-1)}}$ with covariance $a^2 I_{2^{r(L)-1}}$ ($I_{2^{r(L)-1}}$ being the identity matrix on $\mathbb{R}^{2^{r(L)-1}}$). Let also

$$\|x\|_{\infty,L} = \sum_{K=0}^{r(L)-1} \sup_{k \in E(L,K)} |x^{(K,k)}| \text{ and } \|x\|_{2,L} = \left( \sum_{K=0}^{r(L)-1} \sum_{k \in E(L,K)} (x^{(K,k)})^2 \right)^{1/2}.$$ 

For the statements of the lemmas, we refer to Notation 4.4.

**Lemma 5.2** The partial derivatives of $f$ exist almost everywhere and the following inequality holds:

$$\sup_{y \in \mathbb{R}^{2^{(L-1)}}} \sup_{u \in \mathbb{R}^{2^{(L-1)}}} \|u\|_{\infty,L} \leq 1 \Rightarrow |Df(y), u| \leq 1. \quad (5.2)$$

In addition

$$\sup_{K \in \{0, \ldots, r(L)-1\}} \sum_{k_K \in E(L,K)} \left| \frac{\partial f}{\partial x^{(K,k_K)}}(y) \right| \leq 1. \quad (5.3)$$

**Proof of Lemma 5.2.** The first part of the lemma follows directly from the fact that $f$ is Lipschitz with respect to the distance $d^*_r(L)$ together with the Rademacher theorem. We prove now (5.3). For any $K \in \{0, \ldots, r(L)-1\}$, we consider the column vector $u_K = \left( (u^{(i,k)}_K, k_i \in E(L, i))_{i=0,\ldots,r(L)-1} \right)'$ with coordinates given by

$$u^{(i,k)}_K = \text{sign}(\frac{\partial f}{\partial x^{(i,k)}}(y))$$

and

$$u^{(i,k)}_K = 1_{i=K}.$$
Applying the inequality (5.2) together with the fact that $\|u_K\|_{\infty,L} = 1$, we get that
\[
\sum_{k \in \mathcal{E}(L,K)} \left| \frac{\partial f}{\partial x(k)}(y) \right| = |Df(y)\cdot u_K| \leq 1,
\]
and (5.3) follows. \(\diamond\)

**Lemma 5.3** Let \(X\) and \(Y\) be two random variables in \(\mathbb{R}^{2^r(L)-1}\). For any positive integer \(m\) and any \(t \in [0,1]\),
\[
\left| \mathbb{E}(D^m f \ast \varphi_a(Y + tX)X^\otimes m) \right| \leq \mathbb{E}\left( \|Df(\cdot)X\|_\infty \times \|D^{m-1}\varphi_a(\cdot)X^\otimes(m-1)\|_1 \right).
\]

**Proof of Lemma 5.3.** For any positive integer \(m\) and any \(x, y \in \mathbb{R}^{2^r(L)-1}\), it follows, from the properties of the convolution product, that
\[
D^m f \ast \varphi_a(y) x^\otimes m = (Df(\cdot), x) * (D^{m-1}\varphi_a(\cdot), x^\otimes(m-1))(y),
\]
where \(Df(\cdot), x : y \mapsto Df(y), x\) and \(D^{m-1}\varphi_a(\cdot), x^\otimes(m-1) : y \mapsto D^{m-1}\varphi_a(y), x^\otimes(m-1)\). The lemma then follows immediately. \(\diamond\)

**Lemma 5.4** Let \(X\) be a random variable in \(\mathbb{R}^{2^r(L)-1}\). For any nonnegative integer \(m\), there exists a positive constant \(c_m\) depending only on \(m\) such that
\[
\|D^m \varphi_a(\cdot)X^\otimes m\|_1 \leq c_m a^{-m} \|X\|_{2,L}^m. \tag{5.4}
\]

**Proof of Lemma 5.4.** In order to simplify the proof, and to avoid the double indexes \((K, k_K)\) for the coordinates of a column vector of \(\mathbb{R}^{2^r(L)-1}\), we set \(d = 2^r(L) - 1\) and we denote by \(x = (x_1, \ldots, x_d)'\) an element of \(\mathbb{R}^d\). Proceeding by induction on \(m\), we infer that for any \(u, x \in \mathbb{R}^d\) and any integer \(m,\)
\[
D^m \varphi_a(u)x^\otimes m = \frac{1}{(2\pi a^2)^{d/2}} \exp \left( -\frac{1}{2a^2} \sum_{i=1}^d u_i^2 \right) \sum_{\ell=0}^{[m/2]} c_{m,\ell} \prod_{i=1}^d \left( \sum_{\ell=0}^d \frac{|x_i|^2}{a^2} \right)^{\ell/2} \left( \sum_{i=1}^d \frac{u_i x_i}{a} \right)^{m-2\ell}, \tag{5.5}
\]
with the following recurrence relations between the \(c_{m,\ell}\):
\[
c_{m,0} = (-1)^m \text{ for any } m \geq 0, \quad c_{2,1} = -1,
\]
\[
c_{m+1,\ell} = (m - 2\ell + 2)c_{m,\ell-1} - c_{m,\ell} \text{ for } \ell \in \{1, \ldots, [m/2]\} \text{ and } m \geq 2,
\]
\[
c_{m+1,[(m+1)/2]} = c_{m,[m/2]} \text{ if } m \text{ is odd}, \quad c_{m+1,[(m+1)/2]} = c_{m+1,[m/2]} \text{ if } m \text{ is even}.
\]
Starting from (5.5) and setting \(\|x\|_{2,d} = \left( \sum_{i=1}^d x_i^2 \right)^{1/2}\), we get that for any integer \(m,\)
\[
\int_{\mathbb{R}^d} |D^m \varphi_a(u)x^\otimes m| du \leq \frac{\|x\|_{2,d}^m}{a^m(2\pi a^2)^{d/2}} \int_{\mathbb{R}^d} \exp \left( -\frac{1}{2a^2} \sum_{i=1}^d u_i^2 \right) \sum_{\ell=0}^{[m/2]} c_{m,\ell} \prod_{i=1}^d \left( \sum_{\ell=0}^d \frac{|x_i|^2}{a^2} \right)^{\ell/2} \left( \sum_{i=1}^d \frac{u_i x_i}{a} \right)^{m-2\ell} \prod_{i=1}^d du_i
\]
\[
\leq \frac{\|x\|_{2,d}^m}{a^m} \int_{\mathbb{R}^d} \frac{1}{(2\pi)^{d/2}} \exp \left( -\frac{1}{2} \sum_{i=1}^d u_i^2 \right) \sum_{\ell=0}^{m} c_{m,\ell} \prod_{i=1}^d \left( \sum_{\ell=0}^d \frac{|x_i|^2}{a^2} \right)^{\ell/2} \left( \sum_{i=1}^d \frac{u_i x_i}{a} \right)^{m-2\ell} \prod_{i=1}^d du_i.
\]
Now, for any integer \(k\), we have that
\[
\frac{1}{(2\pi)^{d/2}} \int_{\mathbb{R}^d} \exp \left( -\frac{1}{2} \sum_{i=1}^d u_i^2 \right) \prod_{i=1}^d \left( |x_i|^2 \right)^{k/2} \prod_{i=1}^d du_i = \mathbb{E}(|X|^k),
\]
where \(X\) is a standard \(d\)-dimensional Gaussian vector. Therefore, we get
\[
\|D^m \varphi_a(\cdot)X^\otimes m\|_1 \leq c_m a^{-m} \|X\|_{2,L}^m.
\]
where $N \sim N(0,1)$. Therefore

$$\int_{\mathbb{R}^d} |D^m \varphi_a(u) x \otimes m| du \leq a^{-m} \|x\|_{2,d}^{m/2} \sum_{\ell=0}^{[m/2]} |c_{m,\ell}| \mathbb{E}(|N|^{m-2\ell}),$$

which completes the proof of (5.4). $\diamond$

**Lemma 5.5** Let $X$ and $Y$ be two random variables with values in $\mathbb{R}^{2r(L)-1}$. For any positive integer $m$ and any $t \in [0,1]$, there exists a positive constant $c_{m-1}$ depending only on $m$ such that

$$|\mathbb{E}(D^m f * \varphi_a(Y + tX) X \otimes m)| \leq c_{m-1} a^{1-m} \mathbb{E}\left(\|X\|_{\infty,L} \times \|X\|_{m-1,2,L}^{-1}\right).$$

**Proof of Lemma 5.5.** Applying Lemmas 5.3 and 5.4 and using the fact that, by (5.2),

$$\|Df(\cdot) X\|_{\infty,L} \sup_{y \in \mathbb{R}^{2r(L)-1}} \left|\frac{Df(y)}{\|X\|_{\infty,L}} \cdot \frac{X}{\|X\|_{\infty,L}}\right| \leq \|X\|_{\infty,L},$$

the result follows. $\diamond$

**Lemma 5.6** For any $y \in \mathbb{R}^{2r(L)-1}$ and any integer $m \geq 1$, there exists a positive constant $c_m$ depending only on $m$ such that

$$\sup_{(K_i, k_i), i=1, \ldots, m} \left|\frac{\partial^m f * \varphi_a}{\prod_{i=1}^m \partial_x(K_i, k_i)}(y)\right| \leq c_m a^{1-m},$$

where the supremum is taken over all the indexes $K_i \in \{0, \ldots, r(L)-1\}$ and $k_i \in \mathcal{E}(L, K_i)$ for any $i = 1, \ldots, m$.

**Proof of Lemma 5.6.** Notice first that by the properties of the convolution product,

$$\frac{\partial^m f * \varphi_a}{\prod_{i=1}^m \partial_x(K_i, k_i)}(y) = \left(\frac{\partial f}{\partial x(K_i, k_i)} \ast \frac{\partial^{m-1} \varphi_a}{\prod_{i=2}^m \partial_x(K_i, k_i)}\right)(y).$$

Therefore by using (5.3),

$$\left|\frac{\partial^m f * \varphi_a}{\prod_{i=1}^m \partial_x(K_i, k_i)}(y)\right| \leq \left\|\frac{\partial f}{\partial x(K_i, k_i)}\right\|_{\infty} \left\|\frac{\partial^{m-1} \varphi_a}{\prod_{i=2}^m \partial_x(K_i, k_i)}\right\|_1 \leq \left\|\frac{\partial^{m-1} \varphi_a}{\prod_{i=2}^m \partial_x(K_i, k_i)}\right\|_1. \tag{5.6}$$

Let now $h_a$ be the density of the $N(0,a^2)$ distribution, and let

$$S_m = \left\{\ell \in \{0, \ldots, m\}^m \text{ such that } \sum \ell_i = m\right\}.$$

With this notation, we infer that

$$\left\|\frac{\partial^{m-1} \varphi_a}{\prod_{i=2}^m \partial_x(K_i, k_i)}\right\|_1 \leq \sup_{(\ell_1, \ldots, \ell_{m-1}) \in S_{m-1}} \prod_{i=1}^{m-1} \|h^{(\ell_i)}_a\|_1,$$

where $h^{(\ell_i)}_a$ is the $\ell_i$-th derivative of $h_a$. Since for any real $u$, $h^{(\ell_i)}_a(u) = a^{-(\ell_i+1)} h^{(\ell_i)}_1(u/a)$, it follows that $\|h^{(\ell_i)}_1\|_1 = a^{-\ell_i} \|h^{(\ell_i)}_1\|_1$. Therefore

$$\left\|\frac{\partial^{m-1} \varphi_a}{\prod_{i=2}^m \partial_x(K_i, k_i)}\right\|_1 \leq a^{1-m} \sup_{(\ell_1, \ldots, \ell_{m-1}) \in S_{m-1}} \prod_{i=1}^{m-1} \|\ell^{(\ell_i)}_1\|_1. \tag{5.7}$$
Starting from (5.6) and using (5.7) the lemma is proved, with

\[ c_m = \sup_{(\ell_1, \ldots, \ell_{m-1}) \in S_{m-1}} \prod_{i=1}^{m-1} \| h_1^{(\ell_i)} \|_1 \cdot \diamond \]
