June 12, 2008

Abstract

We give a new proof of the Liouville theorem proved by Merle and Zaag for non-negative solutions of the semilinear heat equation with power nonlinearity. Our proof has a pedagogical interest and is based on Kaplan's blow-up criterion.

Mathematical Subject classification: 35K05, 35K55, 35A20.

Keywords: heat equation, Liouville theorem, blow-up, Kaplan's criterion.

1 Introduction

In [MZ98] and [MZ00], Merle and Zaag consider the following semilinear heat equation

$$u_t = \Delta u + |u|^{p-1}u \quad (1)$$

and prove the following Liouville theorem:

Theorem 1 (Merle-Zaag) *Assume that*

$$p > 1 \text{ and } (N - 2)p < N + 2. \quad (2)$$

Consider u a solution of (1) defined for all $(x, t) \in \mathbb{R}^N \times (-\infty, T)$. Assume in addition that $|u(x, t)| \leq C(T - t)^{-\frac{1}{p-1}}$, for some constant $C > 0$. Then $u \equiv 0$ or there exists $T_0 \geq T$ such that for all $(x, t) \in \mathbb{R}^N \times (-\infty, T)$, $u(x, t) = \pm \kappa(T_0 - t)^{-\frac{1}{p-1}}$ with $\kappa = (p - 1)^{-\frac{1}{p-1}}$.

Introducing the following *similarity variables*:

$$y = \frac{x}{\sqrt{T - t}}, \quad s = -\log(T - t), \quad w(y, s) = (T - t)^{\frac{1}{p-1}} u(x, t), \quad (3)$$

equation (1) is transformed in the following equation:

$$w_s = \Delta w - \frac{1}{2}y \cdot \nabla w - \frac{1}{p-1}w + |w|^{p-1}w, \quad (4)$$

and we get another equivalent formulation of the above Liouville theorem.

Theorem 1' (Merle-Zaag) *Assume (2) and consider $w(y, s)$ a bounded solution of (4), defined for all $(y, s) \in \mathbb{R}^N \times \mathbb{R}$. Then w is one of the following solutions: $w \equiv 0$, or $w = \pm \kappa$, or there exist $s_0 \in \mathbb{R}$, such that $w = \pm \varphi(s - s_0)$ with $\varphi(s) = \kappa(1 + e^s)^{-\frac{1}{p-1}}$.*

This theorem introduces a new approach in the study of equation (1), in the sense that it gives uniform estimates both in space and with respect to initial data. For instance, the following localization property is proved in [MZ98] and [MZ00]:

Uniform ODE Behavior: Consider $T \leq T_0$, $\|u_0\|_{C^2(\mathbb{R}^N)} \leq C_0$ and $u(x, t)$ the solution of equation (1), with initial data u_0 . Then, for all $\epsilon > 0$, there is $C(\epsilon, C_0, T_0)$ such that for all $x \in \mathbb{R}^N$ and $t \in [0, T)$,

$$\left| \frac{\partial u}{\partial t}(x, t) - |u|^{p-1}u(x, t) \right| \leq \epsilon |u(x, t)|^p + C.$$

The above uniform estimate allowed to get new blow-up results for equation (1), unknown before, such as the stability of the blow up profile (see Fermanian, Merle and Zaag [FKMZ00]) and the regularity of the blow-up set (see Zaag [Zaa06]).

Moreover, the approach consisting in proving Liouville theorems in order to get new blow-up results has been successful for other parabolic equations with no gradient structure (see Nouaili and Zaag [NZ07]), hyperbolic equations like Korteweg de Vries (Martel and Merle [MM00]) and the wave equation (Merle and Zaag [MZ08]).

In [MZ98] and [MZ00], the authors prove the Liouville theorem in similarity variables. They use the following Lyapunov functional associated with (4):

$$E(w) = \int_{\mathbb{R}^N} \left(\frac{1}{2} |\nabla w|^2 + \frac{|w|^2}{2(p-1)} - \frac{|w|^{p+1}}{p+1} \right) \rho dy, \text{ where } \rho(y) = \frac{e^{-\frac{|y|^2}{4}}}{(4\pi)^{N/2}}. \quad (5)$$

The heart of the proof is the linearization of w (defined by (4)) around κ as $s \rightarrow -\infty$. Using similar ideas to Filippas and Kohn [FK92], Merle and Zaag prove that there are at most three possible ways in which w goes to κ as $s \rightarrow -\infty$. Then, they show that one of the three cases corresponds to $w(y, s) = \varphi(s - s_0)$ for some $s_0 \in \mathbb{R}$ where $\varphi(s) = \kappa(1 + e^s)^{-\frac{1}{p-1}}$. In the other two cases, they find a contradiction using the following blow-up criterion:

Let w be a solution of (4) which satisfies $I(w(s_0)) > 0$ for some $s_0 \in \mathbb{R}$ where

$$I(w(s)) = -2E(w(s)) + \frac{p-1}{p+1} \left(\int_{\mathbb{R}^N} |w(y, s)|^2 \rho(y) dy \right)^{\frac{p+1}{2}}.$$

Then, w blows up at some time $S > s_0$.

In this note, we found that in the nonnegative case (treated in [MZ98]), we could avoid the long and technical linearization around κ as $s \rightarrow -\infty$ and the application of the blow-up criterion. More precisely, we found that the Liouville theorem in the nonnegative

case follows from Kaplan's blow-up criterion for equation (1) (see [Kap63]) and the work of Giga and Kohn (see [GK85], [GK87] and [GK89]), which are more simple ingredients. The aim of this note is to present this more simple proof, which is pedagogically easier than the analysis of [MZ98]. Of course, for unsigned solutions, we cannot escape the proof given in [MZ00], which heavily relies on the preceding paper [MZ98].

We proceed in two sections:

In section 2, for the reader's convenience, we give and prove our version of Kaplan's criterion, making our paper more self contained.

In section 3, we give our proof of the Liouville theorem in the nonnegative case.

Acknowledgment: We would like to thank the referee for his careful reading and helpful remarks. He suggests the use of Kaplan's blow-up criterion instead of Fujita's, which we used in the first version of this paper.

2 Kaplan's blow-up criterion

In the following, we give our version of Kaplan's criterion:

Proposition 2.1 (*Kaplan's blow-up criterion for equation (1)*) *There exists $M > 0$ such that if $V_0(x)$ in $L^\infty(\mathbb{R}^N)$ is nonnegative and satisfies*

$$\forall |x| \leq M, \quad V_0(x) \geq \frac{\kappa}{2},$$

then the solution $V(x, t)$ of equation (1) with initial data V_0 blows up in finite time $T > 0$.

Proof: Here we use Kaplan's method introduced in [Kap63] (see Theorem 8 page 327). Note that since $V_0(x)$ is nonnegative, the same holds for $V(x, t)$ whenever it exists.

We note by $\lambda > 0$ the first eigenvalue of $-\Delta$ on the ball $B(0, M)$ and by $\psi(x)$ the corresponding eigenfunction to λ . In other words, we have

$$\begin{cases} -\Delta\psi &= \lambda\psi \text{ in } B(0, M), \\ \psi &= 0 \text{ on } \partial B(0, M). \end{cases}$$

Note that $\psi(x) \geq 0$ in $B(0, M)$ and from scaling arguments, we have $\lambda = \frac{\lambda_1}{M^2}$, where $\lambda_1 > 0$ is the first eigenvalue of $-\Delta$ on the ball $B(0, 1)$. We also assume that $\int_{B(0, M)} \psi(x) dx = 1$.

We define $\hat{V}(t) = \int_{B(0, M)} V(x, t) \psi(x) dx$. Multiplying both sides of (1) by $\psi(x)$ and integrating over $B(0, M)$, then using Jensen's inequality and integration by parts, we obtain

$$\begin{cases} \hat{V}'(t) &\geq -\lambda_1 \hat{V} + \hat{V}(t)^p \text{ wherever } V \text{ is defined,} \\ \hat{V}(0) &\geq \frac{\kappa}{2}, \end{cases} \quad (6)$$

(see [Kap63] for details).

Now, we note by $\Phi(t)$ the solution of the ODE:

$$\begin{cases} \Phi'(t) &= \Phi(t)^p - \lambda\Phi(t), \\ \Phi(0) &= \frac{\kappa}{2}. \end{cases}$$

Since $\lambda = \frac{\lambda_1}{M^2}$, we can see that taking M large enough, $\Phi(t)$ blows up at some finite time $T_0 > 0$, hence by (6), $\hat{V}(t) \geq \Phi(t)$ and $\hat{V}$ blows up at some earlier time.

Using the fact that $\sup_{x \in \mathbb{R}^N} V(x, t) \geq \hat{V}(t)$, we conclude that $V(x, t)$ blows up in finite time $T > 0$. ■

3 Our new proof of the Liouville Theorem

We consider w a nonnegative, global and bounded solution of (4). We proceed in two steps. First, we find limits $w_{\pm\infty}$ for w as $s \rightarrow \pm\infty$ and reach a conclusion in some trivial cases. In a second step, we focus on the case where $w_{-\infty} = \kappa$ as $s \rightarrow -\infty$ and conclude the proof.

Step 1: Limits of w as $s \rightarrow \pm\infty$

We recall respectively, Theorem 1 and Proposition 5 from [GK85] (page 305 and 309), under the condition (2).

Proposition 3.1 (*Stationary problem of (4) (Giga-Kohn)*) *The only global solutions in $L^\infty(\mathbb{R}^N)$ of*

$$0 = \Delta w - \frac{1}{2}y \cdot \nabla w - \frac{w}{p-1} + |w|^{p-1}w,$$

are the constant ones $w \equiv 0$, $w \equiv -\kappa$ and $w \equiv \kappa$.

Proposition 3.2 (*Limits of w as $s \rightarrow \pm\infty$ (Giga-Kohn)*) *Let w be a bounded global solution of (4) in $\mathbb{R}^N$. Then, $\lim_{s \rightarrow \infty} w(y, s)$ exists and equals 0 or $\pm\kappa$. The convergence takes place in $C^2(B(0, R))$ for any $R > 0$. The corresponding statements holds also for the limits as $s \rightarrow -\infty$.*

From the propositions above and the positivity of w , we have $w_{\pm\infty} \equiv 0$ or $w_{\pm\infty} \equiv \kappa$. Since E is a Lyapunov functional for w , one gets from (4) and (5):

$$0 \leq \int_{-\infty}^{+\infty} ds \int_{\mathbb{R}^N} \left| \frac{\partial w}{\partial s}(y, s) \right|^2 \rho dy = E(w_{-\infty}) - E(w_{+\infty}). \quad (7)$$

Therefore, since $E(\kappa) > 0 = E(0)$, there are only two cases:

- $E(w_{-\infty}) = E(w_{+\infty})$. This implies that $\frac{\partial w}{\partial s} \equiv 0$, hence w is a stationary solution of (4) and $w \equiv 0$ or $w \equiv \kappa$ by Proposition 3.1.
- $E(w_{-\infty}) - E(w_{+\infty}) > 0$. This occurs only if $w_{+\infty} \equiv 0$ and $w_{-\infty} \equiv \kappa$. It remains to treat this case:

Step 2: Case where $w \rightarrow \kappa$ as $s \rightarrow -\infty$

Consider $M > 0$ given by Proposition 2.1. From Proposition 3.2, there is some time s^* negative and large enough such that

$$w(y, s^*) \geq \frac{\kappa}{2} \text{ for all } |y| < M. \quad (8)$$

Introducing $v(x, t)$ defined by

$$v(x, t) = (1-t)^{-\frac{1}{p-1}} w(y, s + s^*) \text{ where } y = \frac{x}{\sqrt{1-t}} \text{ and } s = -\log(1-t), \quad (9)$$

we see that the function v is defined for all $x \in \mathbb{R}^N$ and $t < 1$, satisfies (1) and

$$\forall x \in \mathbb{R}^N, \quad v(x, 0) = w(y, s^*). \quad (10)$$

If we consider $V(x, t)$ the solution of (1) with initial condition $V(x, 0) = v(x, 0)$, then from (8), (10) and Proposition 2.1, we have that V blows up at some finite time $T > 0$. Since we have from uniqueness for (1) that

$$\forall (x, t) \in \mathbb{R}^N \times [0, 1), \quad V(x, t) = v(x, t),$$

this gives $T \geq 1$. Extending $v(x, t)$ for $t \geq 1$ (if ever $T > 1$) by $v(x, t) = V(x, t)$, we see that $v(x, t)$ is a solution of (1) defined for all $(x, t) \in \mathbb{R}^N \times (-\infty, T)$ and which blows up at time $T \geq 1$ (note in particular that (9) still holds)

Now, if we consider $a \in \mathbb{R}^N$ a blow-up point of v and introduce the following *similarity variables*:

$$y' = \frac{x - a}{\sqrt{T - t}}, \quad s' = -\log(T - t), \quad w_a(y', s') = (T - t)^{\frac{1}{p-1}} v(x, t), \quad (11)$$

then, we see from Giga and Kohn [GK87], Theorem 3.7 (page 17) that:

$$\forall s' \in \mathbb{R}, \quad \|w_a(s')\|_{L^\infty} \leq C_1, \quad \text{where } C_1 > 0, \quad (12)$$

and from [GK89], Corollary 3.4 (page 872), that:

$$w_a(y', s') \rightarrow \kappa \text{ as } s' \rightarrow +\infty, \text{ uniformly on compact sets.} \quad (13)$$

In the following, we are looking for the limit of w_a as $s' \rightarrow -\infty$. Using (9) and (11), we obtain:

$$\begin{aligned} w_a(y', s') &= (1 - \sigma)^{-\frac{1}{p-1}} w(y, s) \quad \text{where } \sigma = (T - 1)e^{s'}, \\ y &= \frac{y' + ae^{s'/2}}{\sqrt{1 - \sigma}} \quad \text{and} \quad s = s' - \log(1 - \sigma) + s^*. \end{aligned} \quad (14)$$

Since $w(y, s) \rightarrow \kappa$ as $s \rightarrow -\infty$ uniformly on compact sets and $\sigma \rightarrow 0$ as $s' \rightarrow -\infty$, this gives that

$$w_a(y', s') \rightarrow \kappa \text{ as } s' \rightarrow -\infty, \text{ uniformly on compact sets.} \quad (15)$$

From parabolic regularity and the continuity of the energy $E(w_a)$, we get from (13) and (15)

$$E(w_a(s')) \rightarrow E(\kappa) \text{ as } s' \rightarrow \pm\infty.$$

Using the energy identity (7) for w_a , we conclude that

$$\int_{-\infty}^{+\infty} ds' \int_{\mathbb{R}^N} \left| \frac{\partial w_a}{\partial s}(y', s') \right|^2 \rho dy' = E(\kappa) - E(\kappa) = 0,$$

hence w_a is just a function of y' . Using the bound (12) and Proposition 3.1, we see that w_a is constant. Using limits (13) and (15), this yields $w_a \equiv \kappa$. Consequently, we obtain from (9), (11) and (14):

$$w(y, s) = w_a(y', s') \left(1 + (1 - T)e^{s'} \right)^{1/(p-1)} = \kappa \left(1 + (1 - T)e^{s'} \right)^{1/(p-1)}.$$

Since we have from (14) $e^{s'} = \frac{e^{s-s^*}}{1 + e^{s-s^*}(T-1)}$, we get

$$w(y, s) = \kappa \left(1 + (T-1)e^{s-s^*} \right)^{-1/(p-1)},$$

hence $w(y, s) = \kappa$ if $T = 1$ or $w = \kappa (1 + e^{s-s_0})^{-1/(p-1)}$ if $T > 1$, where $s_0 = -\log(T-1) + s^*$, which is the desired conclusion. This ends the proof of the Liouville Theorem in the nonnegative case.
