ABSTRACT

We propose a transcription on graphs of recent continuous global active contours proposed for image segmentation to address the problem of binary partitioning of data represented by graphs. To do so, using the framework of Partial difference Equations (PdEs), we propose a family of nonlocal regularization functionals that verify the co-area formula on graphs. The gradients of a sub-graph are introduced and their properties studied. Relations, for the case of a sub-graph, between the introduced nonlocal regularization functionals and nonlocal discrete perimeters are exhibited and the co-area formula on graphs is introduced. Finally, nonlocal global minimizers can be considered on graphs with the associated energies. Experiments show the benefits of the approach for nonlocal image segmentation and high dimensional data clustering.

1. INTRODUCTION

With the advent of our digital world, much different kind of data are now available. On the contrary to classical images and videos, these data do not necessarily lie on a Cartesian grid and can be irregularly distributed. To represent a large number of data domains (images, meshes, social networks, etc.), the most natural and flexible representation consists in using weighted graphs by modeling neighborhood relationships. Therefore, there is much interest in the transposition of signal and image processing tools for the processing of functions on graphs, e.g., spectral graph wavelets [1] or PDE on graphs [2, 3]. In this paper, we consider active contour models. They can be casted in two models: geometric models with level sets and variational models with Total Variation. We consider the second model and extend it to the processing of arbitrary data on graphs as well as unify their local and nonlocal processing for images. To do this transcription, we use the framework of PdEs [3] along with a family of discrete gradients. We introduce nonlocal perimeters as well as the co-area on graphs. We then consider nonlocal global minimizers for segmentation and clustering and provide an application example with nonlocal Chan-Vese on graphs.

2. PARTIAL DIFFERENCE EQUATIONS ON GRAPHS

In this section, we recall definitions and operators on graphs. All the operators presented in this section are naturally local and nonlocal [3]. Indeed, local and nonlocal configurations are expressed by graph topology and edges' weights.

2.1. Preliminary notations

A weighted graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, w)$ consists in a finite set \mathcal{V} of vertices and a finite set $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$ of weighted edges. We assume \mathcal{G} to be undirected, with no self-loops and no multiple edges. Let $e_{ij} = (v_i, v_j)$ be the edge of \mathcal{E} that connects vertices v_i and v_j of \mathcal{V} . Its weight, denoted by $w_{ij} = w(v_i, v_j)$, represents the similarity between its vertices and is computed using a positive symmetric function w . Notation $v_i \sim v_j$ is also used to denote two adjacent vertices. The volume of a set of vertices \mathcal{A} can be computed by $\text{vol}(\mathcal{A}) = \sum_{v_i \in \mathcal{A}} d_{\mathcal{A}}(v_i)$ with $d_{\mathcal{A}}(v_i) = \sum_{v_j \sim v_i} w(v_i, v_j)$, $\forall v_i \in \mathcal{A}$ the degree of a vertex relatively to a set of vertices \mathcal{A} . Let $\mathcal{H}(\mathcal{V})$ be the Hilbert space of real-valued functions defined on the vertices of a graph. A function $f : \mathcal{V} \rightarrow \mathbb{R}$ of $\mathcal{H}(\mathcal{V})$ assigns a real value $x_i = f(v_i)$ to each vertex $v_i \in \mathcal{V}$. By analogy with functional analysis on continuous spaces, the integral of a function $f \in \mathcal{H}(\mathcal{V})$, over the set of vertices \mathcal{V} , is defined as $\int_{\mathcal{V}} f = \sum_{\mathcal{V}} f$. Similarly, let $\mathcal{H}(\mathcal{E})$ be the space of real-valued functions defined on the edges of \mathcal{G} . Both Hilbert spaces are endowed with the usual inner products.

2.2. Difference operators

Let $f : \mathcal{V} \rightarrow \mathbb{R}$ be a function of $\mathcal{H}(\mathcal{V})$. The *difference operator* [3] of f , noted $d_w : \mathcal{H}(\mathcal{V}) \rightarrow \mathcal{H}(\mathcal{E})$, is defined on an edge $(v_i, v_j) \in \mathcal{E}$ by: $(d_w f)(v_i, v_j) = w(v_i, v_j)^{1/2}(f(v_j) - f(v_i))$. The *directional derivative* of f , at a vertex $v_i \in \mathcal{V}$, along an edge $e_{ij} = (v_i, v_j)$, is defined as $\left. \frac{\partial f}{\partial e_{ij}} \right|_{v_i} = \partial_{v_j} f(v_i) = (d_w f)(v_i, v_j)$. Based on the difference operator, the weighted morphological *external* and *internal* difference operators are respectively [4]: $(d_w^+ f)(v_i, v_j) = \max(0, (d_w f)(v_i, v_j))$ and $(d_w^- f)(v_i, v_j) = -\min(0, (d_w f)(v_i, v_j))$. The correspond-

ing external and internal partial derivatives are $\partial_v^+ f(v_i) = (d_w^+ f)(v_i, v_j)$ and $\partial_v^- f(v_i) = (d_w^- f)(v_i, v_j)$. The *adjoint* of the difference operator, noted $d_w^* : \mathcal{H}(\mathcal{E}) \rightarrow \mathcal{H}(\mathcal{V})$, is a linear operator defined, for all $f \in \mathcal{H}(\mathcal{V})$ and all $H \in \mathcal{H}(\mathcal{E})$, by $\langle d_w f, H \rangle_{\mathcal{H}(\mathcal{E})} = \langle f, d_w^* H \rangle_{\mathcal{H}(\mathcal{V})}$. This adjoint operator d_w^* , of a function $H \in \mathcal{H}(\mathcal{E})$, can be expressed at a vertex $v_i \in \mathcal{V}$ by the following expression: $(d_w^* H)(v_i) = -\text{div}_w(H)(v_i) = \sum_{v_j \sim v_i} w(v_i, v_j)^{1/2} (H(v_j, v_i) - H(v_i, v_j))$.

2.3. Gradients and norms

The *weighted gradient operator* of a function $f \in \mathcal{H}(\mathcal{V})$, at a vertex $v_i \in \mathcal{V}$, is the vector operator defined by $(\nabla_w \mathbf{f})(\mathbf{v}_i) = [\partial_{v_j} f(v_i) : v_j \sim v_i]^T$. The \mathcal{L}_p norm of this vector is defined by [3]: $\|(\nabla_w \mathbf{f})(\mathbf{v}_i)\|_p^p = \sum_{v_j \sim v_i} w(v_i, v_j)^{p/2} |f(v_j) - f(v_i)|^p$. Similarly, we have $(\nabla_w^\pm \mathbf{f})(\mathbf{v}_i) = [\partial_{v_j}^\pm f(v_i) : v_j \sim v_i]^T$ and $\|(\nabla_w^\pm \mathbf{f})(\mathbf{v}_i)\|_p^p = \sum_{v_j \sim v_i} w(v_i, v_j)^{p/2} |M^\pm(0, f(v_j) - f(v_i))|^p$ with $M^+ = \max$ and $M^- = \min$. These norms exhibit the following property: $\|(\nabla_w \mathbf{f})(\mathbf{v}_i)\|_p^p = \|(\nabla_w^+ \mathbf{f})(\mathbf{v}_i)\|_p^p + \|(\nabla_w^- \mathbf{f})(\mathbf{v}_i)\|_p^p$.

2.4. Anisotropic p -Laplace operator

The *weighted p -Laplace anisotropic operator* of a function $f \in \mathcal{H}(\mathcal{V})$, noted $\Delta_{w,p}^a : \mathcal{H}(\mathcal{V}) \rightarrow \mathcal{H}(\mathcal{V})$, is defined by: $(\Delta_{w,p}^a f)(v_i) = \frac{1}{2} d_w^* (|(d_w f)(v_i, v_j)|^{p-2} (d_w f)(v_i, v_j))$. Using the definitions of d_w and d_w^* , we obtain this expression [5]: $(\Delta_{w,p}^a f)(v_i) = \sum_{v_j \sim v_i} (w_{i,j}^a f)(v_i, v_j) (f(v_i) - f(v_j))$, with $(w_{i,j}^a f)(v_i, v_j) = w_{i,j}^{p/2} |f(v_i) - f(v_j)|^{p-2}$. This operator is nonlinear if $p \neq 2$. In this latter case, it corresponds to the *combinatorial graph Laplacian*.

3. VARIATIONAL FRAMEWORK OF ACTIVE CONTOURS ON GRAPHS

In this section, we introduce a family of nonlocal regularization functionals that verify the co-area formula for $p = 1$. The gradients of a sub-graph are introduced and their properties studied. Then, we show that there are strong relations, for the case of a sub-graph, between the introduced nonlocal regularization functionals and nonlocal discrete perimeters. Finally nonlocal global minimizers can be considered on arbitrary graphs with the associated nonlocal energies.

3.1. Nonlocal regularization functionals

Let us consider nonlocal regularization functionals based on weighted total variation (TV_w) on graphs $R_{w,p} : \mathcal{H}(\mathcal{V}) \rightarrow \mathbb{R}$ of a function $f \in \mathcal{H}(\mathcal{V})$: $R_{w,p}(f) = \sum_{v_i \in \mathcal{V}} \|\mathbf{D}_w \mathbf{f}(\mathbf{v}_i)\|_p^p$ with $0 < p < +\infty$. \mathbf{D}_w is a discrete gradient operator that can be among ∇_w and ∇_w^\pm . By replacing \mathbf{D}_w with the previous discrete operators one obtains several functionals: $R_{w,p}(f) = \sum_{v_i \in \mathcal{V}} \sum_{v_j \sim v_i} w(v_i, v_j)^{p/2} |f(v_j) - f(v_i)|^p$, and

$R_{w,p}^\pm(f) = \sum_{v_j \in \mathcal{V}} \sum_{v_j \sim v_i} w(v_i, v_j)^{p/2} |M^\pm(0, f(v_j) - f(v_i))|^p$ with property $R_{w,p}(f) = R_{w,p}^+(f) + R_{w,p}^-(f)$. Finally, using the chain rule, we can show [5] that $\frac{\partial R_{w,p}^\pm(f)}{\partial f(v_i)} = 2p(\Delta_{w,p}^a f)(v_i)$.

3.2. Nonlocal perimeters and co-area on graphs

3.2.1. Gradients of a sub-graph

Let \mathcal{A} be a set of connected vertices with $\mathcal{A} \subset \mathcal{V}$. We denote by $\partial^+ \mathcal{A}$ and $\partial^- \mathcal{A}$, the *external* and *internal* boundary sets of \mathcal{A} , respectively. $\mathcal{A}^- = \mathcal{V} \setminus \mathcal{A}$ is the complement of \mathcal{A} . For a given vertex $v_i \in \mathcal{V}$, $\partial^+ \mathcal{A} = \{v_i \in \mathcal{A}^- : \exists v_j \in \mathcal{A} \text{ with } (v_i, v_j) \in \mathcal{E}\}$ and $\partial^- \mathcal{A} = \{v_i \in \mathcal{A} : \exists v_j \in \mathcal{A}^- \text{ with } (v_i, v_j) \in \mathcal{E}\}$. We now consider the gradients of a sub-graph and study their properties. We denote by $\chi_{\mathcal{A}}$ the indicator function defined by $\chi : \mathcal{V} \rightarrow \{0, 1\}$.

Proposition 1

For a given vertex, if $v_i \in \mathcal{A}$, then $\chi_{\mathcal{A}}(v_i) = 1$ and $\chi_{\mathcal{A}^-}(v_i) = 0$ otherwise. The \mathcal{L}_p -norm of the directional gradient of the indicator function is defined as:

$$\|\nabla_w^\pm \chi_{\mathcal{A}}(\mathbf{v}_i)\|_p^p = \chi_{\partial^\pm \mathcal{A}}(v_i) \sum_{v_j \sim v_i, v_j \in \mathcal{A}^\pm} w(v_i, v_j)^{p/2} \quad (1)$$

with the notation $\mathcal{A}^+ = \mathcal{A}$ and $\mathcal{A}^- = \mathcal{V} \setminus \mathcal{A}$.

Proof. By studying cases where $v_i \in \mathcal{A}$, $v_i \notin \mathcal{A}$ and similarly with the neighbors of v_i , we can prove that only the inner and outer set of vertices $\partial^\pm \mathcal{A}$ are concerned. ■

This leads to the following property:

$$\|\nabla_w \chi_{\mathcal{A}}(\mathbf{v}_i)\|_p^p = \|\nabla_w^+ \chi_{\mathcal{A}}(\mathbf{v}_i)\|_p^p + \|\nabla_w^- \chi_{\mathcal{A}}(\mathbf{v}_i)\|_p^p$$

3.2.2. Nonlocal functionals and nonlocal perimeters

Now, we show that there are strong relations, for the case of a sub-graph, between the previous discrete regularization functionals and discrete perimeters.

Proposition 2

By replacing f by the indicator function $\chi_{\mathcal{A}}$ in the regularization functionals, one has: $R_{w,p}^\pm(\chi_{\mathcal{A}}) = \frac{1}{2} \text{vol}(\partial \mathcal{A})$.

Proof. Using equation (1) and the nonlocal functionals, $R_{w,p}^+(\chi_{\mathcal{A}}) = \sum_{v_i \in \mathcal{V}} \sum_{v_j \sim v_i, v_j \in \mathcal{A}} w(v_i, v_j)^{p/2} \chi_{\partial^+ \mathcal{A}}(v_i) = \sum_{v_i \in \partial^+ \mathcal{A}} \sum_{v_j \in \partial^- \mathcal{A}} w(v_i, v_j)^{p/2} = \sum_{v_i \in \partial^+ \mathcal{A}} d_{\partial^- \mathcal{A}}(v_i) = \frac{1}{2} \text{vol}(\partial \mathcal{A})$. Similarly, one has $R_{w,p}^-(\chi_{\mathcal{A}}) = \frac{1}{2} \text{vol}(\partial \mathcal{A})$, and $R_{w,p}(\chi_{\mathcal{A}}) = \text{vol}(\partial \mathcal{A})$. ■

All the previous functionals can be then seen as the inner ($R_{w,p}^-(\chi_{\mathcal{A}})$), outer ($R_{w,p}^+(\chi_{\mathcal{A}})$) or global ($R_{w,p}(\chi_{\mathcal{A}})$) p -cost of a cut between two set of vertices \mathcal{A} and \mathcal{A}^- . As a consequence, all these previous expressions can be seen as *nonlocal* discrete perimeters of a sub-graph:

$$2Per_{w,p}^\pm(\mathcal{A}) = Per_{w,p}(\mathcal{A}) = 2R_{w,p}^\pm(\chi_{\mathcal{A}}) = R_{w,p}(\chi_{\mathcal{A}})$$

This shows explicitly the relations between the functionals we defined with Total Variation and nonlocal discrete perimeters of a sub-graph. Interestingly, we can recover on grid graphs with specific weights, a discrete analogue of the continuous nonlocal perimeters introduced in [6].

3.2.3. Co-area formula on weighted graphs

Now we show that for $p = 1$, the introduced nonlocal functionals do verify the co-area formula.

Proposition 3

For any function $f \in \mathcal{H}(\mathcal{V})$ and for $p = 1$, one has the following property:

$$R_{w,1}^*(f) = \int_{-\infty}^{+\infty} R_{w,1}^*(\chi_{\{f>t\}}) dt \quad (2)$$

where $R_{w,1}^*(f)$ is among $R_{w,1}(f)$ and $R_{w,1}^\pm(f)$ with $\chi_{\{f>t\}}(v_i) = 0$ if $f(v_i) < t$ and $\chi_{\{f>t\}}(v_i) = 1$ if $f(v_i) \geq t$.

Proof. All the functionals $R_{w,1}^*$ appearing in (2) are of the form $R_{w,1}(f) = \sum_{v_i \in \mathcal{V}} \sum_{v_j \sim v_i} w(v_i, v_j) |f(v_j) - f(v_i)|$ or $R_{w,1}^\pm(f) = \sum_{v_i \in \mathcal{V}} \sum_{v_j \sim v_i} w(v_i, v_j) (f(v_j) - f(v_i))^\pm$ with $x^+ = \max(0, x)$ is the nonnegative part of the real number x ($x^- = (-x)^+$). Since $|a - b| = \int_{-\infty}^{+\infty} |\chi_{\{a>t\}} - \chi_{\{b>t\}}| dt$ and $(a - b)^\pm = \int_{-\infty}^{+\infty} (\chi_{\{a>t\}} - \chi_{\{b>t\}})^\pm dt$, $R_{w,1}^*$ clearly satisfies (2). ■

This result is different from [7] that assumes that the set of vertices of the graph belong to a submanifold and then make use of the co-area formula on manifolds. Our proposal does not need this assumption and is much simpler since have the co-area formula for any weighted graph with $p = 1$.

3.3. Nonlocal active contours models as global minimizers for segmentation and clustering

The usual drawback of active contours methods is the existence of local minimizers with the solution highly dependent of the initial condition. A recent method, introduced by Bresson and Chan [8, 7], proposes to redefine the active contour model into a model which gives global minimizers. Using our framework we show how we can introduce nonlocal global minimizers of active contours models on graphs. Let us consider this very general minimization problem on graphs:

$$\min_{f: \mathcal{V} \rightarrow \{0,1\}} \{TV_w(f) + \lambda H(f, f^0)\} \quad (3)$$

where $TV_w(f)$ is a weighted total variation of f . Both $TV_w(f)$ and $H(f, f^0)$ are considered as satisfying the co-area formula. When $\lambda \neq 0$, this energy can be considered as the nonlocal discrete analogue on graphs of [7]. When $\lambda = 0$, it is the discrete analogue to the continuous min-cut of [9] since this reduces to minimize $Per_{w,p}^*(\mathcal{A}) = \text{vol}(\partial \mathcal{A}) = \text{cut}(\mathcal{A}, \mathcal{A}^-)$. Now,

we show how such a minimization can be solved but we restrict ourselves to the following minimization problem:

$$\min_{\bar{f}: \mathcal{V} \rightarrow \{0,1\}} \left\{ E_{w,1}(f) = R_{w,1}^*(f) + \lambda \sum_{v_i \in \mathcal{V}} r(f^0(v_i)) f(v_i) \right\} \quad (4)$$

where $R_{w,1}^*(f)$ is among $R_{w,1}(f)$ and $R_{w,1}^\pm(f)$. As previously shown, the first part $R_{w,1}^*(f)$ of the energy $E_{w,p}(f)$ satisfies the co-area formula. It can also be easily shown that it is also the case for the second part of the energy. Minimization problem (4) is non-convex and, as shown in [10] for the continuous analogue, can be reformulated to consider a convex relaxation problem to determine a global minimizing solution. Therefore, a new minimization problem is considered:

$$\min_{\hat{f}: \mathcal{V} \rightarrow [0,1]} \left\{ \hat{E}_{w,1}(f) = R_{w,1}^*(f) + \lambda \sum_{v_i \in \mathcal{V}} r(f^0(v_i)) f(v_i) \right\} \quad (5)$$

Following the approach in [10], one can show, that every level set of a minimizer of (5) is a solution of the original optimization problem (4). As a consequence, to obtain a global solution $\bar{f}: \mathcal{V} \rightarrow \{0, 1\}$ to the problem (4), one thresholds any function $\hat{f}: \mathcal{V} \rightarrow [0, 1]$ that is a solution of (5) and $\bar{f} = \chi_{\mathcal{A}}(\hat{f})$. To establish the solution of the minimization problem (4), we can solve the following system of equations:

$$\frac{\partial \hat{E}_{w,1}(f)}{\partial f(v_i)} = \frac{\partial R_{w,1}^*(f)}{\partial f(v_i)} + \lambda r(f^0(v_i)) = 0, \quad \forall v_i \in \mathcal{V}, \quad (6)$$

First it is easy to show that one has the following relation $\frac{\partial R_{w,1}(f)}{\partial f(v_i)} = 2 \frac{\partial R_{w,1}^+(f)}{\partial f(v_i)} = 2 \frac{\partial R_{w,1}^-(f)}{\partial f(v_i)} = 2 \Delta_{w,1}^a f(v_i)$. To approximate the solution of the minimization problem (5), the algorithms exposed in [7] can be used (dual/projection, graph cuts). We choose to use, for the sake of simplicity, the linearized Gauss-Jacobi method and obtain the following iterative algorithm, $\forall v_i \in \mathcal{V}$:

$$f^{(t+1)}(v_i) = \frac{-\lambda r(f^0(v_i)) + \alpha \sum_{v_j \sim v_i} \gamma_w^{f^{(t)}}(v_i, v_j) f^{(t)}(v_j)}{\alpha \sum_{v_j \sim v_i} \gamma_w^{f^{(t)}}(v_i, v_j)} \quad (7)$$

where $\gamma_w^{f^{(t)}}(v_i, v_j) = w(v_i, v_j)^{1/2} |f^t(v_i) - f^t(v_j)|_{\mathbb{R}}^{-1}$. With $\alpha = 1$ for $R_{w,1}^\pm(f)$ and $\alpha = 2$ for $R_{w,1}(f)$, and the initial condition $f^{(0)} = f^0$. The problem being relaxed on \mathbb{R} , at each iteration t , the solution is projected on $[0, 1]$ by $\max(\min(f^t, 1), 0)$.

4. APPLICATIONS

In the following, we discuss the application of our proposed approach to Chan-Vese (CV) model. Since graphs of the arbitrary topologies can be considered, our approach enables to consider any type of discrete data that can be represented by a

graph. Moreover, it can be used to segment image with non-local configurations and to cluster high dimensional data. We can directly express the discrete analogue on graphs of the CV model as the following minimization, $\forall v_i \in V$:

$$\min_{f: \mathcal{V} \rightarrow \{0,1\}} \left\{ R_{w,1}^*(f) + \lambda \sum_{v_i \in \mathcal{V}} f(v_i)m(c_1, v_i) + (1 - f(v_i))m(c_2, v_i) \right\} \quad (8)$$

where $m(a, v_i) = (a - f^0(v_i))^2$. c_1 and c_2 are the means inside and outside the object. For a fixed f , the minimizer $(c_1(f), c_2(f))$ can be explicitly computed. For fixed (c_1, c_2) , the minimization over f can be solved with algorithm (7) with $r(f^0(v_i)) = (c_1 - f^0(v_i))^2 - (c_2 - f^0(v_i))^2$. Therefore, the minimization of CV model on graphs is performed as an alternate minimization with respect to (c_1, c_2) and with respect to f . Figure 1 shows the application of our CV model on

Fig. 1. Chan-Vese on various graphs (local and nonlocal, super-pixel, mesh, k-nearest neighbors) for image segmentation and data clustering.

many different graphs with $R_{w,1}(f)$. First column presents a noisy textured image with an initial contour, the segmentation result on local (4-adjacency graph with Gaussian weights computed on pixel values) and nonlocal (4-adjacency graph coupled with a 4-Nearest Neighbor graph selected in a 9×9 window and Gaussian weights computed on 3×3 patches) graphs. The benefits of nonlocal patch-based configurations for image segmentation is evident for segmenting textured objects. Second column presents an image with an initial contour, the considered graph (a super-pixel graph obtained from an over-segmentation with Gaussian weights on region mean values), and the obtained partition of the super-pixel graph. This shows the interest of our formulation that can be used on a different representation of the image. Third column presents a mesh with an initial contour (on pig's back), the considered mesh (a triangular mesh with Gaussian weights on vertices grey values) with an image of text projected onto the surface, and the obtained partition of the mesh (all the text is extracted). Again, the algorithm remains the same, only graph

changes. Our approach on meshes is therefore much more general than the recent framework proposed in [11]. Last column presents an example of high-dimensional data classification: an image database with an initial random partition, the considered graph (a 10 nearest neighbors graph weighted with Gaussian weights on 16×16 vectors associated to the image of each vertex). This shows how our CV models can be used in the space of images for classification; our CV model also corresponding a TV-regularized 2-means on graphs.

5. CONCLUSION

In this paper we proposed nonlocal PDEs on graphs for active contours models with applications to image segmentation and data clustering. Starting from nonlocal regularization functionals on graphs, we showed they verify the co-area formula on graphs and introduced nonlocal perimeters on graphs. These ingredients are then used for nonlocal active contours models as global minimizers for segmentation and clustering. Experimental results with the Chan-Vese models showed the benefits of the approach that enables to perform the binary partitioning of any graph.
