The economic returns of bonding and bridging social capital for immigrant men in Germany

Bram Lancee

Abstract. Using longitudinal data, this paper analyses the effect of different forms of social capital on the likelihood of employment and the occupational status of first generation immigrant men in Germany. This allows me to examine to what extent social capital of the bonding and the bridging type yield different returns. It is studied how contacts with natives, co-ethnic ties and family-based social capital are beneficial to the economic position of immigrant men. Random effects and fixed effects models show that strong inter-ethnic ties are beneficial both for employment and occupational status. There is no effect of co-ethnic ties and family-based social capital. It is concluded that, also when using panel data, bridging social capital contributes to a better economic position and bonding social capital does not.

Keywords: Social capital; labour market; immigrants; longitudinal analysis; Germany.

Introduction

One of the main challenges that Western countries are faced with is how to deal with the increasing share of immigrants and their descendants. The incorporation of immigrants into the labour market of the host society is of utmost importance to social cohesion. One of the approaches to explain labour market outcomes of immigrants is to use social capital theory. Research that examines the relation between immigrants' social capital and its economic returns is scarce but growing steadily, for example with respect to employment (Aguilera 2002, Kalter 2006, Lancee 2010), income (Mouw 2002, Aguilera and Massey 2003, Aguilera 2005, Amuedo-Dorantes and Mundra 2008), self-employment (Kanas et al. 2009b) and occupational status (Sanders and Nee 1996, Kanas et al. 2009a). The general conclusion is that social capital helps immigrants to make headway on the labour market.

1
2
3 Recent discussions on social capital distinguish between 'bonding' and 'bridging'
4 (Putnam 2000, Burt 2001). Loosely defined, bonding refers to within-group connections, while
5 bridging social capital refers to between-group connections. Distinguishing between different
6 forms of social capital seems particularly important with regard to immigrants. For immigrants,
7 especially social capital of the bridging type is expected to yield positive returns since it
8 implies building much needed host-country specific capital (Kalter 2006, Haug 2007, Lancee
9 and Hartung 2011). However, returns with respect to bonding social capital may not be that
10 straightforward. Networks of immigrants are often characterized as isolated and therefore
11 hindering economic integration (Portes 1998b). On the other hand, immigrants are repeatedly
12 characterized as having a social network that is based on ethnic solidarity (see for example
13 Sanders and Nee 1996, Sanders et al. 2002, Waldinger 2005).

14
15
16 It is often suggested that whereas bonding social capital is "to get by", bridging social
17 capital is "to get ahead" (Putnam 2000, p. 23). This seems to hold for immigrants' social
18 capital too (See for example Kanas et al. 2009b, Lancee 2010). However, previous studies
19 predominantly rely on cross-sectional data. The major problem with cross-sectional data is
20 that it cannot solve the problems of unobserved heterogeneity and reversed causality. One of
21 the main challenges in estimating the effect of social capital is that of homophily: people
22 connect with those who are similar to them (see for a review McPherson et al. 2001, Mouw
23 2006). In the words of Mouw (2003, p. 869): '(...) if successful people prefer to socialize with
24 other successful people, this would result in a correlation between friends' income and
25 occupational status, even in the absence of a causal effect of social capital on labour market
26 outcomes'. Many studies analysing the effect of social capital rely on cross-sectional data, or
27 use longitudinal models that do not solve the problem of unobserved heterogeneity. Hence,
28 estimates of social capital may be biased. There are only few studies on the economic
29 incorporation of immigrants that analyze the impact of both bonding and bridging social
30 capital simultaneously and none uses longitudinal data.

31
32
33 The contribution of this paper is twofold. First, I contribute to the field by analysing the
34 economic returns of two main forms of social capital simultaneously for immigrants in
35 Germany. Second, the paper better estimates the effect of social capital by making use of

9 10 **Theory and hypotheses**

11 Social capital refers to the resources that are potentially available in one's network. A social
12 network can be considered a capital, which can produce returns in order to improve
13 (economic) well-being. There is no commonly accepted definition of social capital. In this
14 paper, I follow Lin (1999, p. 30) and see social capital as 'investment and use of embedded
15 resources in social relations for expected returns'.

23 *Bridging social capital*

24
25 Bridging social capital is referred to as the building of connections between heterogeneous
26 groups (Schuller et al. 2000), or, in the words of Putnam (2007, p. 143) as 'ties to people
27 "unlike" you in some important way'. In the migration literature, bridging social capital usually
28 refers to contacts with natives (see, for example Putnam 2007, Nannestad et al. 2008, Kanas
29 et al. 2009b, Lancee 2010). The advantage of bridging ties is that unique information and
30 opportunities come into reach (Putnam 2000, p. 22). It is well established in the literature that
31 for immigrants, contacts with natives are important cross-cutting ties (Portes 1998a, Heath
32 and Yu 2005, Haug 2008).
33
34
35
36
37
38
39
40

41 Bridging social capital, seen as bridging the ethnic divide is beneficial to immigrants
42 because it provides access to host country specific resources. Moreover, it provides unique
43 information about labour market opportunities. The idea of social capital being a *capital* – in
44 the sense that investments yield positive returns – is based on the assumption that social
45 relations connect people to valuable resources (see for example Flap and Völker 2004).
46 According to Nederveen Pieterse (2003), inter-ethnic relations help immigrants to get access
47 to helpful resources beyond their homogenous ethnic networks. In other words, migrants with
48 ties to the native population gain access to host-country specific resources.
49
50
51
52
53
54
55
56

57 There is ample evidence that for successful integration in the labour market of the host
58 society, migrants need host-country specific skills (Borjas 1994, Duleep and Regets 1999,
59 Friedberg 2000, Zeng and Xie 2004, Kanas and Van Tubergen 2009). The argument of the
60

1
2
3 need for host-country specific capital is predominantly made with respect to human capital,
4 such as educational attainment and language proficiency (Chiswick and Miller 2002).
5
6
7 However, this argument is also central to bridging social capital: by building inter-ethnic ties,
8
9 migrants realize access to resources that they have typically little of themselves. Contacts
10
11 with natives hence help to make headway on the labour market because it implies getting
12
13 access to much needed host-country specific resources, for example by getting help with
14
15 applications, translating adverts, finding vacancies, or assistance on how to present oneself
16
17 to employers (Aguilera and Massey 2003).

18
19 Furthermore, as Haug (2003) points out, 'since (...) in Germany most employers are
20
21 Germans, it is useful for immigrants to have contacts to Germans.' Because most employers
22
23 are native residents it is helpful to have ties with natives. Moreover, since natives are, on
24
25 average, higher educated and have better jobs themselves, they are more likely to be well
26
27 informed and able to point to better jobs. Earlier studies indeed find that contacts with natives
28
29 help immigrants to make headway on the labour market, both with respect to employment as
30
31 well as occupational status (see, for example, Aguilera and Massey 2003, Kalter 2006, Kanas
32
33 et al. 2009b, Lancee 2010).

34
35 Hence, the first hypothesis reads: *Bridging social capital positively affects both the*
36
37 *likelihood to be employed and occupational status.*

40 41 *Bonding social capital*

42
43 Bonding social capital is usually referred to as within-group connections. The underlying
44
45 principle is that of network closure (Coleman 1990, Burt 2005). In the case of total closure in
46
47 a network, all people are connected with one another. The clearest case of a network with a
48
49 high degree of closure is probably the family (Coleman 1988). In their "forms of capital" model
50
51 for immigrant incorporation into the labour market, Nee and Sanders (2001, p. 388)
52
53 emphasize the pivotal role of the family (see also Sanders and Nee 1996). Their general
54
55 argument is that '[t]he mode of incorporation is largely a function of the social, human-cultural
56
57 capital of immigrant families and how these resources are used by individuals within and
58
59 apart from the existing structure of ethnic networks and institutions' .
60

1
2
3 Not only family ties contribute to a network with a high degree of closure. One could
4
5 classify all ties with co-ethnics as contributing to a dense network with closure (see Sanders
6
7 2002, for a review of studies on social relations and closure in ethnic communities). Portes
8
9 and Sensenbrenner (1993) identify two sources of social capital. "Bounded solidarity" involves
10
11 a sense of group solidarity that manifests as a reaction to real or perceived threats of a group,
12
13 and "enforceable trust", the monitoring and sanctioning capacity of a group. Sanders (2002, p.
14
15 348) concludes: '[r]esearch leaves little doubt as to the importance of social capital derived
16
17 through ethnic networks in promoting economic action.' Bonding social capital is hence
18
19 measured as ties with co-ethnics and as the strength of ties with the extended family.
20

21
22 With respect to its returns, there are two competing arguments. On the one hand,
23
24 bonding social capital may result in better labour market outcomes. The key advantage of
25
26 closure in a network is superior information and a high degree of solidarity. As opposed to
27
28 inter-ethnic ties, co-ethnic ties may profit from ethnic solidarity (Sanders 2002). Hence, the
29
30 more closure in a network, the more likely the sharing and exchange of resources (Lin 2001,
31
32 p. 66). There is evidence that, for immigrants, the main source of information on jobs is
33
34 through relatives and friends, particularly those who belong to the same ethnic origin (Zhou
35
36 1992, Waldinger 1994, Pichler 1997, Menjivar 2000). Ethnic networks can function as a
37
38 means to make headway on the labour market, since these networks rely on ethnic solidarity
39
40 and enforceable trust (Portes and Sensenbrenner 1993, Portes 1995, Waldinger 1995). Nee
41
42 and Sanders conclude (2001, pp. 389-90): '(...) especially for immigrants who do not possess
43
44 substantial financial capital, the family (nuclear and extended) constitutes the most important
45
46 capital asset. (...) The social capital embodied in family relationships promotes cooperation
47
48 needed in realizing both economic and non-economic values.' Elliott (2001, but see also
49
50 Stainback 2008) finds that Latinos are more likely than natives to enter jobs by matching
51
52 people and jobs through ethnic social networks. Patacchini and Zenou (2008) find that ethnic
53
54 networks in Britain increase the probability of finding employment.

55
56 On the other hand, immigrants' bonding social capital is characterized as isolated.
57
58 Consequently, if jobs are found through ethnic and family networks, they are likely to be
59
60 inferior (Nee and Sanders 2001). The argument is that resources accessed through a network
of co-ethnics and family members do not provide unique information; they hence do not result

1
2
3 in opportunities for upward mobility on the labour market. When being embedded into ethnic
4 networks only, successful upward mobility may be impeded due to social obligations,
5 pressure to conformity, or “downward levelling norms” (Portes, 1998). Such mobility traps can
6 consequently lead to ethnic segmentation or “downward assimilation” (Portes, 1995). The
7 embedding into ethnic networks may prevent contacts with the host society and thus hamper
8 integration (Haug 2007: 100). Lancee (2010) does not find an effect of family-based social
9 capital for immigrants in the Netherlands with respect to employment and income. Elliott
10 (1999) concludes that job referrals based on co-ethnic ties result in jobs that are paid worse
11 for immigrants in the US.

12
13 It seems that bonding social capital may help to find a job; it however does not help to
14 find a *better* job. Therefore, the second hypothesis is twofold: *Bonding social capital positively*
15 *affects the likelihood to be employed* and secondly, *for employed men, bonding social capital*
16 *does not affect occupational status*.

30 31 **Data and measurement**

32 *Sample*

33
34 For the measurement, I make use of the German Socio-Economic Panel Survey (GSOEP), a
35 panel study with a yearly questionnaire since 1984 (Wagner et al. 1993). In 1996, 2001 and
36 2006 the survey included a module on social networks. Because of this, the panel used in this
37 analysis is restricted to the years 1996-2007. The GSOEP oversamples immigrants and
38 contains four immigrant sub-samplesⁱ with extensive information on migration history and
39 specific questionnaire items. The initial response rate for the immigrant sample varied from
40 64.7 percent for Italians, to 70 percent for Turks. Response rates for subsequent waves were
41 considerably higher.

42
43 As with all panels, the GSOEP is subject to attrition, which could bias the results
44 (Riphahn 2004). The main sources of attrition were refusal and unsuccessful follow-up;
45 special measures were taken to reduce attrition, such as contacting respondents again each
46 year until all members of the household refused for two consecutive years (Kroh and Spieß
47 2008). The average attrition rate of the immigrant samples is 22%. (Haisken-DeNew and
48 Frick 2005, p. 160). In the research sample, the attrition rate is 14.3%ⁱⁱ; attrition was not
49

52
53
54
55
56
57
58
59
60

1
2
3 related to a specific ethnic group. However, attrition could be related to return-migration and
4 consequently bias the sample towards long-term migrants. The fact that the average years of
5 stay in Germany is just over 23 years indicates that the sample is indeed most representative
6 for long-term migrants. In addition, the GSOEP 'foreigner' sample is in fact a guest worker
7 sample of which the vast part is to stay for good. When one compares the research sample to
8 the ethnic minority population in Germany, the classic guest worker groups are indeed over-
9 represented (Turks, Ex-Yugoslavians, Greeks, Italians, Spanish and Portuguese), the other
10 groups are under-represented (Eastern Europe, EU Western, and non EU).

People are classified as an immigrant if they are born outside Germany and do not
have a German nationalityⁱⁱⁱ. The sample is restricted to men because employment careers,
as well as social networks differ substantially among (immigrant) men and women (Hagan
1998, Livingston 2006). The sample for the analysis of the likelihood of employment consists
of all men aged eighteen till sixty-five. Those who are in school, performing military or civil
service, or those retired earlier than age sixty-five are excluded from the sample. For the
analyses of occupational status, the sample is furthermore restricted to people who work
either full-time or regular part-time. Missing values are replaced with information available
from earlier waves. In the years between the measurements of social capital items,
respondents were given the last known value of this item (following Kalter 2006).

Method of estimation

One of the problems in empirical research on the effects of social capital is that of reversed
causality. It may well be that more social capital results in better labour market outcomes, but
it is also likely that a better position on the labour market results in more social capital (see
Mouw 2006, for a recent review on the measurement of causality in social capital). That is,
one could meet people just after finding a job, and this could result in a correlation between
social capital and employment that is caused by employment, rather than by social contacts.
For that reason, indicators of social capital are lagged one year. By doing so, social capital is
measured at an earlier point in time than employment and occupational status.

Another problem in cross-sectional research is the problem of unobserved
heterogeneity: an effect can be due to enduring differences between people, rather than

1
2
3 because of having acquired social capital. Mouw (2006, but see also Halaby 1994) reviews
4 the studies on social capital that aim to estimate a causal relationship, and is most favourable
5 towards studies that apply fixed effects models.
6
7

8
9 The fixed effects (FE) model estimates an intercept for each individual in the model.
10 The FE model uses each variable's difference from its within-individual mean and hence can
11 estimate only coefficients that have within-individual variation (Mouw 2006, Rabe-Hesketh
12 and Skrondal 2008). The big advantage of the FE model is that it controls for all differences
13 between individuals, thereby eliminating unobserved heterogeneity (Halaby 2004). The
14 disadvantage of FE models is that it is not possible to estimate time-constant covariates, such
15 as ethnic origin. Another disadvantage is that, because FE models only use within-individual
16 variation, they are –by definition– more sensitive to attrition. Last, in its logistic variant,
17 individuals without variation on the dependent variable are excluded from the analysis since
18 they don't provide information for the likelihood function.
19
20
21
22
23
24
25
26
27

28 The random effects (RE) model assumes a randomly varying intercept, and the
29 intercept is a draw from some distribution for each unit, and it is independent of the error for a
30 particular observation (Rabe-Hesketh and Skrondal 2008). The advantage of the RE model is
31 that it uses within- and between-individual information; hence also time-constant covariates
32 be estimated. Moreover, the RE estimator is more efficient. Last, the logistic variant of the RE
33 model does not require within-individual variation on the dependent variable and therefore
34 makes use of the complete sample. The major drawback is that the random intercept is
35 assumed to be uncorrelated with the covariates; it therefore cannot control for unobserved
36 individual characteristics. Therefore, although RE models use the panel structure of the data,
37 they do not solve the problem of unobserved heterogeneity (Halaby 2004).
38
39
40
41
42
43
44
45
46
47

48 Since FE and RE models have advantages as well as disadvantages, I estimate both.
49 A Hausman test is performed to see which model is to be preferred from a statistical point of
50 view.
51
52
53

54 55 56 *Measures*

57 The likelihood of employment is measured as being fulltime or regular part-time employed, as
58 opposed to being unemployed, looking for a job or not working. The occupational status is
59
60

1
2
3 measured by the International Socio-Economic Index of Occupational Status (ISEI)
4
5 (Ganzeboom et al. 1992), which summarizes the power, income and required educational
6
7 achievement associated with the various positions in the occupational structure.
8

9
10 Three variables are constructed to measure bonding social capital. In 1996, 2001 and
11
12 2006 the GSOEP contains a module named 'social networks and persons to confide in'. In
13
14 this module, people are asked to mention up to three people outside their household that are
15
16 important to them. The introduction phrase reads: 'Now some questions about your friends
17
18 and acquaintances: Please think of three friends or relatives or other people whom you go out
19
20 with or meet often. Please do not include relatives or other people who live in the same
21
22 household as you'. Ties are subsequently classified as 'Is from another country or is
23
24 foreigner' or as 'Is from one of the old/new Federal states'. For ties classified as 'from another
25
26 country or foreigner', it is asked whether the respondent comes from the same country as the
27
28 person mentioned. If this is the case, the ties are included as bonding social capital.

29
30 In 1996 and 2001, a module is available containing questions about people's relatives
31
32 outside the household. Respondents are asked to indicate which family members they have
33
34 and how strong their relationship is. The introduction phrase reads: 'Now a question
35
36 concerning family members who don't live at home: Which ones and how many of the
37
38 following relatives do you have?' Subsequently, respondents are asked 'For those relatives
39
40 that you do have how close is your relationship?' (no relationship, fleeting, average, close,
41
42 very close). From these items, a construct called "Strength of family ties" is built. Reliability
43
44 analysis (Cronbach's alpha 1996: .82, 2001: .81) clearly shows that these items can be seen
45
46 as underlying measures of a single construct. As a proxy for family network size, I also
47
48 include the number of family members.

49
50 The following variables are included to measure bridging social capital. First, a variable
51
52 containing the ties mentioned above which are classified as coming 'from the old/new Federal
53
54 states'^{iv}. The second measure for bridging social capital is a construct labelled "Visiting native
55
56 Germans at home". Every second year, respondents were asked whether they visited
57
58 Germans at their home previous year (yes / no) and whether they received visits at home by
59
60 Germans in the previous year (yes / no, Cronbach's alpha ranging from .80 to .87 across
waves).

1
2
3 The measures of social capital have to be seen in the light of some limitations. First,
4 since social capital is not measured every survey year, but every five years (apart from
5 “visiting native Germans”, which is measured every second year), there is little within-
6 individual variation. This complicates the estimation of a causal effect. Partly, this is solved by
7 estimating RE models, which use between-individual information to obtain the estimates.
8 Nonetheless, when FE models *do* indicate a significant impact of social capital, this is strong
9 support for the existence of a causal relationship. A second limitation concerns the diversity of
10 social capital measures available in the GSOEP: the measures for bonding and bridging are
11 not symmetrical. Unfortunately, there is no indicator available for network size of one’s
12 bridging social capital. Furthermore, bridging social capital is most likely underestimated
13 when it concerns weak ties. There is consensus that the ties mentioned in name generator
14 items (like the German friend item) are biased towards strong ties (see for example Van der
15 Gaag and Snijders 2004). In that respect, weak ties in Granovetter’s (1973) sense are not
16 included fully, insofar they are not captured by the visiting Germans at home construct. Last,
17 none of the items used can identify the tie’s occupational position, or whether the person
18 mentioned is ego’s employer. It is therefore not possible to test whether socio-economic
19 characteristics are bridged in addition to ethnicity.
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34
35

36 Notwithstanding these limitations, I argue that the measures are a good proxy of
37 bonding and bridging social capital. Although the indicators do not cover all family and co-
38 ethnic ties, somebody scoring high on the measured bonding indicators is likely to do so on
39 the ties that are not measured. Likewise, when a respondent mentions inter-ethnic ties among
40 the three people whom he goes out with and meets often, and/or if he visits native Germans
41 at their home, this is likely to be a good proxy for the contacts with natives in his network.
42
43
44
45
46
47
48
49
50

51 *Control variables*

52 The following control variables are included. The educational attainment of the respondent, as
53 measured using the CASMIN scheme^v. Furthermore, a dummy variable is included indicating
54 whether or not the respondent attended school in Germany. I also control for German
55 language proficiency, consisting of a scale of three items, measured every second year^{vi}. The
56 items included are “Language usually spoken” (German, mostly that of country of origin,
57
58
59
60

1
2
3 equally), “Own opinion of spoken German”, “Own opinion of written German”. Furthermore, I
4 control for the number of years of full-time working experience (also squared), the number of
5 years since migration, marital status and the ethnic origin of the respondent. For the analyses
6 of occupational status, a dummy for working part-time is included, as well as the number of
7 hours worked per week. To control for differences across regions, dummies for the German
8 federal states are included^{vii}. These dummies intend to capture any regional factors affecting
9 labour market outcomes, such as regional unemployment levels or job opportunities
10 (Constant and Massey 2005). Last, to control for a time trend, dummies for each survey year
11 are included. In table 1, the descriptive statistics are presented. It was checked for multi-
12 collinearity, but this was not a problem.

27
28

29 Results

30 In table 2, model 1, a RE model is presented that predicts the likelihood to be employed.
31 Inter-ethnic ties increase the likelihood to be employed. The number of family members has a
32 negative impact on employment, but the odds ratio is very close to one, indicating the effect
33 size is almost zero. The other measures of social capital do not significantly affect the
34 likelihood to be employed. Coefficients estimated with an RE model are based on within- and
35 between-individual variation. This implies that the coefficient for inter-ethnic ties expresses
36 the difference of having more versus less social capital (the between-individual variation), *and*
37 acquiring more (or less) social capital over time (the within-individual variation). Although
38 theoretically this is the best estimate because all information is used, it can be the case that
39 the between-individual variation is biased by unmeasured personal characteristics
40 (unobserved heterogeneity).
41
42
43
44
45
46
47
48
49
50
51

52 In model 2, a FE model is presented. The FE estimator is based only on within-
53 individual variation. Hence, only over-time changes in social capital are captured. This implies
54 that respondents who do not report changes in their social capital do not influence the
55 estimation of the coefficient. However, since these respondents do influence the standard
56 error, they are included in the sample. The time-constant covariates are dropped, as they
57
58
59
60

1
2
3 don't provide any within-individual information. Logistic FE models require within-individual
4 variation on the dependent variable. As a result, the number of observations is much lower.
5
6 Therefore, the FE sample is different from the RE sample. However, as Halaby (2004) notes,
7
8 estimating FE models is not throwing away information, but making use of the panel structure
9
10 of the data. Moreover, to make sure that outliers do not drive the findings in the FE model, its
11
12 standard errors are obtained by bootstrapping.
13

14
15 As can be seen in model 2, the coefficient of inter-ethnic ties remains significant and
16
17 changes very little in size. Since this is a FE model, this effect is not due to unobserved
18
19 differences between individuals that are time-constant. Furthermore, with respect to possible
20
21 time-variant characteristics, the model controls for changes in marital status and working
22
23 experience. Since the model includes dummies for each survey year, the effect is neither
24
25 spurious with a time trend. In other words, it is not the case that the effect of inter-ethnic ties
26
27 is due to, for example, changes in economic circumstances that occurred in the observation
28
29 period.
30

31 To summarize, people that reported an increase in their inter-ethnic friends are more
32
33 likely to be employed at a later point in time (FE and RE model); furthermore, people that
34
35 have more inter-ethnic friends than others, are more likely to be employed the year after (RE
36
37 model). The coefficient of inter-ethnic ties is slightly larger in the FE than in the RE model.
38
39 This can have three reasons. First, because the FE model only includes people for whom a
40
41 change in the dependent variable is observed, the sample is different from the RE sample. If
42
43 inter-ethnic ties indeed help finding a job, it seems likely that the effect is larger when a model
44
45 is estimated including only those people that change their employment status. Second, the
46
47 coefficient of inter-ethnic ties might be larger because the FE sample is selective^{viii}, for
48
49 example due to attrition (Riphahn 2004). When attrition is not random, it can bias the
50
51 estimates. This would be the case when people that leave the panel are, for example,
52
53 dominantly those that report a decrease in inter-ethnic ties and find employment afterwards.
54
55 Third, the coefficient could be larger because there are unobserved characteristics, like
56
57 ability, that are not controlled for in the RE model. As discussed, both RE and FE models
58
59 have its (dis)advantages. The similar results with regard to significance and effect size is,
60
61 however, a good indicator for the reliability of the results.

2
3
4
5 <TABLE 3 ABOUT HERE>
6
7
8

9
10 In table 3, the effect of indicators of social capital on occupational status is predicted. To
11 make them comparable within the models, all covariates are standardized between zero and
12 one. In addition to the variables that are included in the analysis of employment, I include
13 three extra ones: working part-time, being self-employed and the number of hours worked in
14 a week. In the RE model (model 4), it appears that only inter-ethnic ties affect occupational
15 status. There is no effect of visiting native Germans. Hence, only the “strongest” inter-ethnic
16 ties affect occupational status. Just as in the analysis of employment, diversifying one’s
17 network with inter-ethnic ties positively impacts occupational status. As hypothesized, high
18 closure in one’s family network and intra-ethnic ties is not associated with immigrants’
19 occupational status. When estimating a FE model (model 5), the results are similar. Based on
20 these models, we can conclude that having more inter-ethnic ties than other people results in
21 a higher occupational status. Furthermore, acquiring more inter-ethnic ties over time results in
22 a higher occupational status. The coefficient of inter-ethnic ties is slightly lower in the FE
23 model. This is most likely because in the FE model all between-individual differences are
24 controlled for; its coefficients are therefore not biased by unobserved heterogeneity.
25
26
27
28
29
30
31
32
33
34
35
36
37
38

39 It could be that the returns to social capital are different for the ethnic groups included.
40 Therefore, by including interactions with ethnic group and each of the indicators of social
41 capital it was tested whether this was the case. None of the interactions appeared significant.
42 Furthermore, one could argue that the effect of social capital is different for people that
43 attended school in Germany (Kanas and Van Tubergen 2009). However, none of the
44 interactions between attending school in Germany and indicators of social capital appeared
45 significant.

56 **Conclusion**

57
58 In this paper, I analysed the effect of bonding and bridging social capital on the likelihood of
59 employment and occupational status for first-generation male immigrants in Germany. Based
60

1
2
3 on the argument of access to host-country specific resources, I hypothesized that bridging
4 social capital positively affects both outcomes. Furthermore, based on the argument of
5 network closure I hypothesized that bonding social capital positively affects employment.
6
7 Using the isolation argument, I argued that bonding social capital is not associated with
8 occupational status.
9

10
11
12
13 These hypotheses were tested with longitudinal data and by estimating both random
14 and fixed effects models. Previous studies dominantly relied on cross-sectional data, which
15 suffer from the problems of reversed causality and unobserved heterogeneity. By making use
16 of longitudinal data, it was possible to estimate the effect of acquiring more social capital
17 over-time, as well as the effect of having more social capital than others. Moreover,
18 estimating fixed effects models ensure that the effects are not due to differences between
19 people that are not controlled for (unobserved heterogeneity). Furthermore, indicators of
20 social capital were measured one year before the labour market outcomes.
21
22
23
24
25
26
27
28

29 The findings partly confirmed the expectations. Having contacts with natives
30 positively impacts both employment and occupational status. That is, immigrants who have
31 more close friends that are native German (both over-time as well as in comparison with
32 others) are more likely to be employed and have a higher occupational status the year after.
33 However, there is no effect of visiting Germans at home. Based on these findings, can we
34 conclude that there is a causal effect of bridging social capital on labour market outcomes?
35 One has to keep in mind that only ethnic bridges are measured. Therefore, it might be the
36 case that ties are bridging on the ethnic dimension, but bonding with regard to socio-
37 economic characteristics. McPherson et al. (2001, p. 415) suggest that bridging the ethnic
38 divide is more important than bridging across occupations: 'Homophily in race and ethnicity
39 creates the strongest divides in our personal environments, with age, religion, education,
40 occupation, and gender following in roughly that order.' However, data on the socio-economic
41 status of the ties would be desirable in order to describe the social composition of the
42 networks. This way, one could examine if socio-economic variables are bridged in addition to
43 ethnicity, and refine the results related to the resource argument. A second limitation that has
44 to be mentioned is that only strong(er) inter-ethnic ties are measured. One therefore does not

1
2
3 know whether the results are the same for people's entire network. Further research is
4
5 needed that can also include people's weak ties.
6

7 As hypothesized, bonding social capital is not associated with occupational status.
8
9 Contrary to the expectations, however, also with regard to employment, immigrants in
10
11 Germany do not profit from co-ethnic and family-based social capital. This supports the
12
13 'isolation' rather than the 'closure' argument: closure may indicate a high level of solidarity
14
15 and enforceable trust, but it does not result in valuable information or support that is useful in
16
17 finding a job. Since people in the sample are dominantly long-term immigrants, an alternative
18
19 explanation might be the ongoing incorporation of immigrants in German society. Sanders
20
21 (2002, p. 348) concludes: 'When social boundaries take on less of a gate-keeper function
22
23 protecting ethnically generated resources and more of a bridging function encouraging
24
25 greater intergroup association, the identity-preserving influence of ethnic boundaries is likely
26
27 to decline'. Also Hagan (1998) concludes that, especially shortly after arrival, family-based
28
29 and co-ethnic networks offer the resources needed to find jobs. Since the sample consists
30
31 mostly of long term-migrants, it could hence be that bonding social capital did have its value
32
33 in the past, but is no longer relevant after a substantial number of years in the host society.
34

35 Keeping in mind the conceptualization of bonding and bridging social capital, as well as
36
37 the limitations of the data, it seems that in the case of male immigrants in Germany, whereas
38
39 bridging is to get ahead, bonding is indeed to get by.

52 Notes

53
54
55 ⁱ Immigrants are either included in the “foreigner” sample, (started in 1984, consisting of Turks,
56 Yugoslavians, Greeks, Italians and Spanish), in the “immigrant sample” (started in 1994/1995,
57 consisting of households in which at least one member moved from abroad to Germany), or in
58 the “refreshment” sample (1998 and 2000).

ii The attrition rate is most likely lower because only the working age population is included.

iii Persons with a German nationality were not included because the construct “visiting Germans at home” was not asked in all waves to people with a German nationality. Furthermore, they were not included to make sure that the ties mentioned are measured as bridging and bonding in the same way for the whole sample.

iv. This classification effectively separates native Germans and ethnic minorities. In one case it is less clear. Ties that belong to the second generation *and* have German citizenship could be classified as either ‘from another country or as ‘from the old/new Federal states’. In the follow-up question (‘Do you come from the same country [as the person mentioned]’), it appeared that in 98% of the cases people indicate them to be from the same country as they are themselves (for people born in Germany but no German citizenship, this percentage is 93). That is, the country referred to is the country of origin. This is most likely the same when immigrants classify ties that belong to the second generation and with a German nationality.

v The categories are slightly collapsed: included are inadequately/general elementary (originally separate categories), basic vocational, intermediate vocational/general (originally separate categories), general or vocational maturity certificate and tertiary education. Models were also estimated including parental education. This did not yield different results.

vi Cronbach’s alpha ranging from .83 to .86 across waves.

vii Due to the low N in some of the states several categories are collapsed: Mecklenburg-Western Pomerania, Brandenburg, Saxony, Saxony-Anhalt and Thuringia are collapsed in one category.

viii However, the Hausman test favours the FE model. Furthermore, the standard errors of the FE model are robust.
