# The economic returns of bonding and bridging social capital for immigrant men in Germany

Bram Lancee

**Abstract.** Using longitudinal data, this paper analyses the effect of different forms of social capital on the likelihood of employment and the occupational status of first generation immigrant men in Germany. This allows me to examine to what extent social capital of the bonding and the bridging type yield different returns. It is studied how contacts with natives, co-ethnic ties and family-based social capital are beneficial to the economic position of immigrant men. Random effects and fixed effects models show that strong inter-ethnic ties are beneficial both for employment and occupational status. There is no effect of co-ethnic ties and family-based social capital. It is concluded that, also when using panel data, bridging social capital contributes to a better economic position and bonding social capital does not.

**Keywords:** Social capital; labour market; immigrants; longitudinal analysis; Germany.

## Introduction

One of the main challenges that Western countries are faced with is how to deal with the increasing share of immigrants and their descendants. The incorporation of immigrants into the labour market of the host society is of utmost importance to social cohesion. One of the approaches to explain labour market outcomes of immigrants is to use social capital theory. Research that examines the relation between immigrants' social capital and its economic returns is scarce but growing steadily, for example with respect to employment (Aguilera 2002, Kalter 2006, Lancee 2010), income (Mouw 2002, Aguilera and Massey 2003, Aguilera 2005, Amuedo-Dorantes and Mundra 2008), self-employment (Kanas et al. 2009b) and occupational status (Sanders and Nee 1996, Kanas et al. 2009a). The general conclusion is that social capital helps immigrants to make headway on the labour market.

1  
2  
3 Recent discussions on social capital distinguish between 'bonding' and 'bridging'  
4 (Putnam 2000, Burt 2001). Loosely defined, bonding refers to within-group connections, while  
5 bridging social capital refers to between-group connections. Distinguishing between different  
6 forms of social capital seems particularly important with regard to immigrants. For immigrants,  
7 especially social capital of the bridging type is expected to yield positive returns since it  
8 implies building much needed host-country specific capital (Kalter 2006, Haug 2007, Lancee  
9 and Hartung 2011). However, returns with respect to bonding social capital may not be that  
10 straightforward. Networks of immigrants are often characterized as isolated and therefore  
11 hindering economic integration (Portes 1998b). On the other hand, immigrants are repeatedly  
12 characterized as having a social network that is based on ethnic solidarity (see for example  
13 Sanders and Nee 1996, Sanders et al. 2002, Waldinger 2005).

14  
15  
16 It is often suggested that whereas bonding social capital is "to get by", bridging social  
17 capital is "to get ahead" (Putnam 2000, p. 23). This seems to hold for immigrants' social  
18 capital too (See for example Kanas et al. 2009b, Lancee 2010). However, previous studies  
19 predominantly rely on cross-sectional data. The major problem with cross-sectional data is  
20 that it cannot solve the problems of unobserved heterogeneity and reversed causality. One of  
21 the main challenges in estimating the effect of social capital is that of homophily: people  
22 connect with those who are similar to them (see for a review McPherson et al. 2001, Mouw  
23 2006). In the words of Mouw (2003, p. 869): '(...) if successful people prefer to socialize with  
24 other successful people, this would result in a correlation between friends' income and  
25 occupational status, even in the absence of a causal effect of social capital on labour market  
26 outcomes'. Many studies analysing the effect of social capital rely on cross-sectional data, or  
27 use longitudinal models that do not solve the problem of unobserved heterogeneity. Hence,  
28 estimates of social capital may be biased. There are only few studies on the economic  
29 incorporation of immigrants that analyze the impact of both bonding and bridging social  
30 capital simultaneously and none uses longitudinal data.

31  
32  
33 The contribution of this paper is twofold. First, I contribute to the field by analysing the  
34 economic returns of two main forms of social capital simultaneously for immigrants in  
35 Germany. Second, the paper better estimates the effect of social capital by making use of

### 8 9 10 **Theory and hypotheses**

11 Social capital refers to the resources that are potentially available in one's network. A social  
12 network can be considered a capital, which can produce returns in order to improve  
13 (economic) well-being. There is no commonly accepted definition of social capital. In this  
14 paper, I follow Lin (1999, p. 30) and see social capital as 'investment and use of embedded  
15 resources in social relations for expected returns'.

#### 23 *Bridging social capital*

24  
25 Bridging social capital is referred to as the building of connections between heterogeneous  
26 groups (Schuller et al. 2000), or, in the words of Putnam (2007, p. 143) as 'ties to people  
27 "unlike" you in some important way'. In the migration literature, bridging social capital usually  
28 refers to contacts with natives (see, for example Putnam 2007, Nannestad et al. 2008, Kanas  
29 et al. 2009b, Lancee 2010). The advantage of bridging ties is that unique information and  
30 opportunities come into reach (Putnam 2000, p. 22). It is well established in the literature that  
31 for immigrants, contacts with natives are important cross-cutting ties (Portes 1998a, Heath  
32 and Yu 2005, Haug 2008).  
33  
34  
35  
36  
37  
38  
39  
40

41 Bridging social capital, seen as bridging the ethnic divide is beneficial to immigrants  
42 because it provides access to host country specific resources. Moreover, it provides unique  
43 information about labour market opportunities. The idea of social capital being a *capital* – in  
44 the sense that investments yield positive returns – is based on the assumption that social  
45 relations connect people to valuable resources (see for example Flap and Völker 2004).  
46 According to Nederveen Pieterse (2003), inter-ethnic relations help immigrants to get access  
47 to helpful resources beyond their homogenous ethnic networks. In other words, migrants with  
48 ties to the native population gain access to host-country specific resources.  
49  
50  
51  
52  
53  
54  
55  
56

57 There is ample evidence that for successful integration in the labour market of the host  
58 society, migrants need host-country specific skills (Borjas 1994, Duleep and Regets 1999,  
59 Friedberg 2000, Zeng and Xie 2004, Kanas and Van Tubergen 2009). The argument of the  
60

1  
2  
3 need for host-country specific capital is predominantly made with respect to human capital,  
4 such as educational attainment and language proficiency (Chiswick and Miller 2002).  
5  
6 However, this argument is also central to bridging social capital: by building inter-ethnic ties,  
7 migrants realize access to resources that they have typically little of themselves. Contacts  
8 with natives hence help to make headway on the labour market because it implies getting  
9 access to much needed host-country specific resources, for example by getting help with  
10 applications, translating adverts, finding vacancies, or assistance on how to present oneself  
11 to employers (Aguilera and Massey 2003).  
12  
13  
14  
15  
16  
17  
18

19 Furthermore, as Haug (2003) points out, 'since (...) in Germany most employers are  
20 Germans, it is useful for immigrants to have contacts to Germans.' Because most employers  
21 are native residents it is helpful to have ties with natives. Moreover, since natives are, on  
22 average, higher educated and have better jobs themselves, they are more likely to be well  
23 informed and able to point to better jobs. Earlier studies indeed find that contacts with natives  
24 help immigrants to make headway on the labour market, both with respect to employment as  
25 well as occupational status (see, for example, Aguilera and Massey 2003, Kalter 2006, Kanas  
26 et al. 2009b, Lancee 2010).  
27  
28  
29  
30  
31  
32  
33

34 Hence, the first hypothesis reads: *Bridging social capital positively affects both the*  
35 *likelihood to be employed and occupational status.*  
36  
37  
38

#### 39 40 41 *Bonding social capital*

42 Bonding social capital is usually referred to as within-group connections. The underlying  
43 principle is that of network closure (Coleman 1990, Burt 2005). In the case of total closure in  
44 a network, all people are connected with one another. The clearest case of a network with a  
45 high degree of closure is probably the family (Coleman 1988). In their "forms of capital" model  
46 for immigrant incorporation into the labour market, Nee and Sanders (2001, p. 388)  
47 emphasize the pivotal role of the family (see also Sanders and Nee 1996). Their general  
48 argument is that '[t]he mode of incorporation is largely a function of the social, human-cultural  
49 capital of immigrant families and how these resources are used by individuals within and  
50 apart from the existing structure of ethnic networks and institutions'.  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Not only family ties contribute to a network with a high degree of closure. One could  
4  
5 classify all ties with co-ethnics as contributing to a dense network with closure (see Sanders  
6  
7 2002, for a review of studies on social relations and closure in ethnic communities). Portes  
8  
9 and Sensenbrenner (1993) identify two sources of social capital. "Bounded solidarity" involves  
10  
11 a sense of group solidarity that manifests as a reaction to real or perceived threats of a group,  
12  
13 and "enforceable trust", the monitoring and sanctioning capacity of a group. Sanders (2002, p.  
14  
15 348) concludes: '[r]esearch leaves little doubt as to the importance of social capital derived  
16  
17 through ethnic networks in promoting economic action.' Bonding social capital is hence  
18  
19 measured as ties with co-ethnics and as the strength of ties with the extended family.  
20

21 With respect to its returns, there are two competing arguments. On the one hand,  
22  
23 bonding social capital may result in better labour market outcomes. The key advantage of  
24  
25 closure in a network is superior information and a high degree of solidarity. As opposed to  
26  
27 inter-ethnic ties, co-ethnic ties may profit from ethnic solidarity (Sanders 2002). Hence, the  
28  
29 more closure in a network, the more likely the sharing and exchange of resources (Lin 2001,  
30  
31 p. 66). There is evidence that, for immigrants, the main source of information on jobs is  
32  
33 through relatives and friends, particularly those who belong to the same ethnic origin (Zhou  
34  
35 1992, Waldinger 1994, Pichler 1997, Menjivar 2000). Ethnic networks can function as a  
36  
37 means to make headway on the labour market, since these networks rely on ethnic solidarity  
38  
39 and enforceable trust (Portes and Sensenbrenner 1993, Portes 1995, Waldinger 1995). Nee  
40  
41 and Sanders conclude (2001, pp. 389-90): '(...) especially for immigrants who do not possess  
42  
43 substantial financial capital, the family (nuclear and extended) constitutes the most important  
44  
45 capital asset. (...) The social capital embodied in family relationships promotes cooperation  
46  
47 needed in realizing both economic and non-economic values.' Elliott (2001, but see also  
48  
49 Stainback 2008) finds that Latinos are more likely than natives to enter jobs by matching  
50  
51 people and jobs through ethnic social networks. Patacchini and Zenou (2008) find that ethnic  
52  
53 networks in Britain increase the probability of finding employment.

54 On the other hand, immigrants' bonding social capital is characterized as isolated.  
55  
56 Consequently, if jobs are found through ethnic and family networks, they are likely to be  
57  
58 inferior (Nee and Sanders 2001). The argument is that resources accessed through a network  
59  
60 of co-ethnics and family members do not provide unique information; they hence do not result

1  
2  
3 in opportunities for upward mobility on the labour market. When being embedded into ethnic  
4  
5 networks only, successful upward mobility may be impeded due to social obligations,  
6  
7 pressure to conformity, or “downward levelling norms” (Portes, 1998). Such mobility traps can  
8  
9 consequently lead to ethnic segmentation or “downward assimilation” (Portes, 1995). The  
10  
11 embedding into ethnic networks may prevent contacts with the host society and thus hamper  
12  
13 integration (Haug 2007: 100). Lancee (2010) does not find an effect of family-based social  
14  
15 capital for immigrants in the Netherlands with respect to employment and income. Elliott  
16  
17 (1999) concludes that job referrals based on co-ethnic ties result in jobs that are paid worse  
18  
19 for immigrants in the US.

20  
21 It seems that bonding social capital may help to find a job; it however does not help to  
22  
23 find a *better* job. Therefore, the second hypothesis is twofold: *Bonding social capital positively*  
24  
25 *affects the likelihood to be employed* and secondly, *for employed men, bonding social capital*  
26  
27 *does not affect occupational status*.

## 30 31 **Data and measurement**

### 32 33 *Sample*

34  
35 For the measurement, I make use of the German Socio-Economic Panel Survey (GSOEP), a  
36  
37 panel study with a yearly questionnaire since 1984 (Wagner et al. 1993). In 1996, 2001 and  
38  
39 2006 the survey included a module on social networks. Because of this, the panel used in this  
40  
41 analysis is restricted to the years 1996-2007. The GSOEP oversamples immigrants and  
42  
43 contains four immigrant sub-samples<sup>i</sup> with extensive information on migration history and  
44  
45 specific questionnaire items. The initial response rate for the immigrant sample varied from  
46  
47 64.7 percent for Italians, to 70 percent for Turks. Response rates for subsequent waves were  
48  
49 considerably higher.

50  
51 As with all panels, the GSOEP is subject to attrition, which could bias the results  
52  
53 (Riphahn 2004). The main sources of attrition were refusal and unsuccessful follow-up;  
54  
55 special measures were taken to reduce attrition, such as contacting respondents again each  
56  
57 year until all members of the household refused for two consecutive years (Kroh and Spieß  
58  
59 2008). The average attrition rate of the immigrant samples is 22%. (Haisken-DeNew and  
60  
Frick 2005, p. 160). In the research sample, the attrition rate is 14.3%<sup>ii</sup>; attrition was not

1  
2  
3 related to a specific ethnic group. However, attrition could be related to return-migration and  
4  
5 consequently bias the sample towards long-term migrants. The fact that the average years of  
6  
7 stay in Germany is just over 23 years indicates that the sample is indeed most representative  
8  
9 for long-term migrants. In addition, the GSOEP 'foreigner' sample is in fact a guest worker  
10  
11 sample of which the vast part is to stay for good. When one compares the research sample to  
12  
13 the ethnic minority population in Germany, the classic guest worker groups are indeed over-  
14  
15 represented (Turks, Ex-Yugoslavians, Greeks, Italians, Spanish and Portuguese), the other  
16  
17 groups are under-represented (Eastern Europe, EU Western, and non EU).

18  
19 People are classified as an immigrant if they are born outside Germany and do not  
20  
21 have a German nationality<sup>iii</sup>. The sample is restricted to men because employment careers,  
22  
23 as well as social networks differ substantially among (immigrant) men and women (Hagan  
24  
25 1998, Livingston 2006). The sample for the analysis of the likelihood of employment consists  
26  
27 of all men aged eighteen till sixty-five. Those who are in school, performing military or civil  
28  
29 service, or those retired earlier than age sixty-five are excluded from the sample. For the  
30  
31 analyses of occupational status, the sample is furthermore restricted to people who work  
32  
33 either full-time or regular part-time. Missing values are replaced with information available  
34  
35 from earlier waves. In the years between the measurements of social capital items,  
36  
37 respondents were given the last known value of this item (following Kalter 2006).

#### 38 39 40 41 *Method of estimation*

42  
43 One of the problems in empirical research on the effects of social capital is that of reversed  
44  
45 causality. It may well be that more social capital results in better labour market outcomes, but  
46  
47 it is also likely that a better position on the labour market results in more social capital (see  
48  
49 Mouw 2006, for a recent review on the measurement of causality in social capital). That is,  
50  
51 one could meet people just after finding a job, and this could result in a correlation between  
52  
53 social capital and employment that is caused by employment, rather than by social contacts.  
54  
55 For that reason, indicators of social capital are lagged one year. By doing so, social capital is  
56  
57 measured at an earlier point in time than employment and occupational status.

58  
59 Another problem in cross-sectional research is the problem of unobserved  
60  
heterogeneity: an effect can be due to enduring differences between people, rather than

1  
2  
3 because of having acquired social capital. Mouw (2006, but see also Halaby 1994) reviews  
4 the studies on social capital that aim to estimate a causal relationship, and is most favourable  
5 towards studies that apply fixed effects models.  
6  
7

8  
9 The fixed effects (FE) model estimates an intercept for each individual in the model.  
10 The FE model uses each variable's difference from its within-individual mean and hence can  
11 estimate only coefficients that have within-individual variation (Mouw 2006, Rabe-Hesketh  
12 and Skrondal 2008). The big advantage of the FE model is that it controls for all differences  
13 between individuals, thereby eliminating unobserved heterogeneity (Halaby 2004). The  
14 disadvantage of FE models is that it is not possible to estimate time-constant covariates, such  
15 as ethnic origin. Another disadvantage is that, because FE models only use within-individual  
16 variation, they are –by definition– more sensitive to attrition. Last, in its logistic variant,  
17 individuals without variation on the dependent variable are excluded from the analysis since  
18 they don't provide information for the likelihood function.  
19  
20  
21  
22  
23  
24  
25  
26  
27

28  
29 The random effects (RE) model assumes a randomly varying intercept, and the  
30 intercept is a draw from some distribution for each unit, and it is independent of the error for a  
31 particular observation (Rabe-Hesketh and Skrondal 2008). The advantage of the RE model is  
32 that it uses within- and between-individual information; hence also time-constant covariates  
33 be estimated. Moreover, the RE estimator is more efficient. Last, the logistic variant of the RE  
34 model does not require within-individual variation on the dependent variable and therefore  
35 makes use of the complete sample. The major drawback is that the random intercept is  
36 assumed to be uncorrelated with the covariates; it therefore cannot control for unobserved  
37 individual characteristics. Therefore, although RE models use the panel structure of the data,  
38 they do not solve the problem of unobserved heterogeneity (Halaby 2004).  
39  
40  
41  
42  
43  
44  
45  
46  
47

48  
49 Since FE and RE models have advantages as well as disadvantages, I estimate both.  
50 A Hausman test is performed to see which model is to be preferred from a statistical point of  
51 view.  
52  
53

#### 54 55 56 *Measures*

57  
58 The likelihood of employment is measured as being fulltime or regular part-time employed, as  
59 opposed to being unemployed, looking for a job or not working. The occupational status is  
60

1  
2  
3 measured by the International Socio-Economic Index of Occupational Status (ISEI)  
4  
5 (Ganzeboom et al. 1992), which summarizes the power, income and required educational  
6  
7 achievement associated with the various positions in the occupational structure.  
8

9  
10 Three variables are constructed to measure bonding social capital. In 1996, 2001 and  
11  
12 2006 the GSOEP contains a module named 'social networks and persons to confide in'. In  
13  
14 this module, people are asked to mention up to three people outside their household that are  
15  
16 important to them. The introduction phrase reads: 'Now some questions about your friends  
17  
18 and acquaintances: Please think of three friends or relatives or other people whom you go out  
19  
20 with or meet often. Please do not include relatives or other people who live in the same  
21  
22 household as you'. Ties are subsequently classified as 'Is from another country or is  
23  
24 foreigner' or as 'Is from one of the old/new Federal states'. For ties classified as 'from another  
25  
26 country or foreigner', it is asked whether the respondent comes from the same country as the  
27  
28 person mentioned. If this is the case, the ties are included as bonding social capital.

29  
30 In 1996 and 2001, a module is available containing questions about people's relatives  
31  
32 outside the household. Respondents are asked to indicate which family members they have  
33  
34 and how strong their relationship is. The introduction phrase reads: 'Now a question  
35  
36 concerning family members who don't live at home: Which ones and how many of the  
37  
38 following relatives do you have?' Subsequently, respondents are asked 'For those relatives  
39  
40 that you do have how close is your relationship?' (no relationship, fleeting, average, close,  
41  
42 very close). From these items, a construct called "Strength of family ties" is built. Reliability  
43  
44 analysis (Cronbach's alpha 1996: .82, 2001: .81) clearly shows that these items can be seen  
45  
46 as underlying measures of a single construct. As a proxy for family network size, I also  
47  
48 include the number of family members.

49  
50 The following variables are included to measure bridging social capital. First, a variable  
51  
52 containing the ties mentioned above which are classified as coming 'from the old/new Federal  
53  
54 states'<sup>iv</sup>. The second measure for bridging social capital is a construct labelled "Visiting native  
55  
56 Germans at home". Every second year, respondents were asked whether they visited  
57  
58 Germans at their home previous year (yes / no) and whether they received visits at home by  
59  
60 Germans in the previous year (yes / no, Cronbach's alpha ranging from .80 to .87 across  
waves).

1  
2  
3 The measures of social capital have to be seen in the light of some limitations. First,  
4 since social capital is not measured every survey year, but every five years (apart from  
5 “visiting native Germans”, which is measured every second year), there is little within-  
6 individual variation. This complicates the estimation of a causal effect. Partly, this is solved by  
7 estimating RE models, which use between-individual information to obtain the estimates.  
8 Nonetheless, when FE models *do* indicate a significant impact of social capital, this is strong  
9 support for the existence of a causal relationship. A second limitation concerns the diversity of  
10 social capital measures available in the GSOEP: the measures for bonding and bridging are  
11 not symmetrical. Unfortunately, there is no indicator available for network size of one’s  
12 bridging social capital. Furthermore, bridging social capital is most likely underestimated  
13 when it concerns weak ties. There is consensus that the ties mentioned in name generator  
14 items (like the German friend item) are biased towards strong ties (see for example Van der  
15 Gaag and Snijders 2004). In that respect, weak ties in Granovetter’s (1973) sense are not  
16 included fully, insofar they are not captured by the visiting Germans at home construct. Last,  
17 none of the items used can identify the tie’s occupational position, or whether the person  
18 mentioned is ego’s employer. It is therefore not possible to test whether socio-economic  
19 characteristics are bridged in addition to ethnicity.  
20

28  
29  
30  
31  
32  
33  
34  
35

36  
37 Notwithstanding these limitations, I argue that the measures are a good proxy of  
38 bonding and bridging social capital. Although the indicators do not cover all family and co-  
39 ethnic ties, somebody scoring high on the measured bonding indicators is likely to do so on  
40 the ties that are not measured. Likewise, when a respondent mentions inter-ethnic ties among  
41 the three people whom he goes out with and meets often, and/or if he visits native Germans  
42 at their home, this is likely to be a good proxy for the contacts with natives in his network.

#### 51 *Control variables*

52 The following control variables are included. The educational attainment of the respondent, as  
53 measured using the CASMIN scheme<sup>v</sup>. Furthermore, a dummy variable is included indicating  
54 whether or not the respondent attended school in Germany. I also control for German  
55 language proficiency, consisting of a scale of three items, measured every second year<sup>vi</sup>. The  
56 items included are “Language usually spoken” (German, mostly that of country of origin,  
57  
58  
59  
60

1  
2  
3 equally), “Own opinion of spoken German”, “Own opinion of written German”. Furthermore, I  
4 control for the number of years of full-time working experience (also squared), the number of  
5 years since migration, marital status and the ethnic origin of the respondent. For the analyses  
6 of occupational status, a dummy for working part-time is included, as well as the number of  
7 hours worked per week. To control for differences across regions, dummies for the German  
8 federal states are included<sup>vii</sup>. These dummies intend to capture any regional factors affecting  
9 labour market outcomes, such as regional unemployment levels or job opportunities  
10 (Constant and Massey 2005). Last, to control for a time trend, dummies for each survey year  
11 are included. In table 1, the descriptive statistics are presented. It was checked for multi-  
12 collinearity, but this was not a problem.

## 29 Results

30 In table 2, model 1, a RE model is presented that predicts the likelihood to be employed.  
31 Inter-ethnic ties increase the likelihood to be employed. The number of family members has a  
32 negative impact on employment, but the odds ratio is very close to one, indicating the effect  
33 size is almost zero. The other measures of social capital do not significantly affect the  
34 likelihood to be employed. Coefficients estimated with an RE model are based on within- and  
35 between-individual variation. This implies that the coefficient for inter-ethnic ties expresses  
36 the difference of having more versus less social capital (the between-individual variation), *and*  
37 acquiring more (or less) social capital over time (the within-individual variation). Although  
38 theoretically this is the best estimate because all information is used, it can be the case that  
39 the between-individual variation is biased by unmeasured personal characteristics  
40 (unobserved heterogeneity).  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51

52 In model 2, a FE model is presented. The FE estimator is based only on within-  
53 individual variation. Hence, only over-time changes in social capital are captured. This implies  
54 that respondents who do not report changes in their social capital do not influence the  
55 estimation of the coefficient. However, since these respondents do influence the standard  
56 error, they are included in the sample. The time-constant covariates are dropped, as they  
57  
58  
59  
60

1  
2  
3 don't provide any within-individual information. Logistic FE models require within-individual  
4 variation on the dependent variable. As a result, the number of observations is much lower.  
5  
6 Therefore, the FE sample is different from the RE sample. However, as Halaby (2004) notes,  
7  
8 estimating FE models is not throwing away information, but making use of the panel structure  
9  
10 of the data. Moreover, to make sure that outliers do not drive the findings in the FE model, its  
11  
12 standard errors are obtained by bootstrapping.  
13  
14

15  
16 As can be seen in model 2, the coefficient of inter-ethnic ties remains significant and  
17  
18 changes very little in size. Since this is a FE model, this effect is not due to unobserved  
19  
20 differences between individuals that are time-constant. Furthermore, with respect to possible  
21  
22 time-variant characteristics, the model controls for changes in marital status and working  
23  
24 experience. Since the model includes dummies for each survey year, the effect is neither  
25  
26 spurious with a time trend. In other words, it is not the case that the effect of inter-ethnic ties  
27  
28 is due to, for example, changes in economic circumstances that occurred in the observation  
29  
30 period.

31  
32 To summarize, people that reported an increase in their inter-ethnic friends are more  
33  
34 likely to be employed at a later point in time (FE and RE model); furthermore, people that  
35  
36 have more inter-ethnic friends than others, are more likely to be employed the year after (RE  
37  
38 model). The coefficient of inter-ethnic ties is slightly larger in the FE than in the RE model.  
39  
40 This can have three reasons. First, because the FE model only includes people for whom a  
41  
42 change in the dependent variable is observed, the sample is different from the RE sample. If  
43  
44 inter-ethnic ties indeed help finding a job, it seems likely that the effect is larger when a model  
45  
46 is estimated including only those people that change their employment status. Second, the  
47  
48 coefficient of inter-ethnic ties might be larger because the FE sample is selective<sup>viii</sup>, for  
49  
50 example due to attrition (Riphahn 2004). When attrition is not random, it can bias the  
51  
52 estimates. This would be the case when people that leave the panel are, for example,  
53  
54 dominantly those that report a decrease in inter-ethnic ties and find employment afterwards.  
55  
56 Third, the coefficient could be larger because there are unobserved characteristics, like  
57  
58 ability, that are not controlled for in the RE model. As discussed, both RE and FE models  
59  
60 have its (dis)advantages. The similar results with regard to significance and effect size is,  
however, a good indicator for the reliability of the results.

1  
2  
3  
4  
5 <TABLE 3 ABOUT HERE>  
6  
7  
8

9 In table 3, the effect of indicators of social capital on occupational status is predicted. To  
10 make them comparable within the models, all covariates are standardized between zero and  
11 one. In addition to the variables that are included in the analysis of employment, I include  
12 three extra ones: working part-time, being self-employed and the number of hours worked in  
13 a week. In the RE model (model 4), it appears that only inter-ethnic ties affect occupational  
14 status. There is no effect of visiting native Germans. Hence, only the “strongest” inter-ethnic  
15 ties affect occupational status. Just as in the analysis of employment, diversifying one’s  
16 network with inter-ethnic ties positively impacts occupational status. As hypothesized, high  
17 closure in one’s family network and intra-ethnic ties is not associated with immigrants’  
18 occupational status. When estimating a FE model (model 5), the results are similar. Based on  
19 these models, we can conclude that having more inter-ethnic ties than other people results in  
20 a higher occupational status. Furthermore, acquiring more inter-ethnic ties over time results in  
21 a higher occupational status. The coefficient of inter-ethnic ties is slightly lower in the FE  
22 model. This is most likely because in the FE model all between-individual differences are  
23 controlled for; its coefficients are therefore not biased by unobserved heterogeneity.

39 It could be that the returns to social capital are different for the ethnic groups included.  
40 Therefore, by including interactions with ethnic group and each of the indicators of social  
41 capital it was tested whether this was the case. None of the interactions appeared significant.  
42 Furthermore, one could argue that the effect of social capital is different for people that  
43 attended school in Germany (Kanas and Van Tubergen 2009). However, none of the  
44 interactions between attending school in Germany and indicators of social capital appeared  
45 significant.

## 56 **Conclusion**

57 In this paper, I analysed the effect of bonding and bridging social capital on the likelihood of  
58 employment and occupational status for first-generation male immigrants in Germany. Based  
59  
60

1  
2  
3 on the argument of access to host-country specific resources, I hypothesized that bridging  
4 social capital positively affects both outcomes. Furthermore, based on the argument of  
5 network closure I hypothesized that bonding social capital positively affects employment.  
6  
7 Using the isolation argument, I argued that bonding social capital is not associated with  
8 occupational status.  
9

10  
11  
12  
13 These hypotheses were tested with longitudinal data and by estimating both random  
14 and fixed effects models. Previous studies dominantly relied on cross-sectional data, which  
15 suffer from the problems of reversed causality and unobserved heterogeneity. By making use  
16 of longitudinal data, it was possible to estimate the effect of acquiring more social capital  
17 over-time, as well as the effect of having more social capital than others. Moreover,  
18 estimating fixed effects models ensure that the effects are not due to differences between  
19 people that are not controlled for (unobserved heterogeneity). Furthermore, indicators of  
20 social capital were measured one year before the labour market outcomes.  
21  
22  
23  
24  
25  
26  
27  
28

29 The findings partly confirmed the expectations. Having contacts with natives  
30 positively impacts both employment and occupational status. That is, immigrants who have  
31 more close friends that are native German (both over-time as well as in comparison with  
32 others) are more likely to be employed and have a higher occupational status the year after.  
33 However, there is no effect of visiting Germans at home. Based on these findings, can we  
34 conclude that there is a causal effect of bridging social capital on labour market outcomes?  
35 One has to keep in mind that only ethnic bridges are measured. Therefore, it might be the  
36 case that ties are bridging on the ethnic dimension, but bonding with regard to socio-  
37 economic characteristics. McPherson et al. (2001, p. 415) suggest that bridging the ethnic  
38 divide is more important than bridging across occupations: 'Homophily in race and ethnicity  
39 creates the strongest divides in our personal environments, with age, religion, education,  
40 occupation, and gender following in roughly that order.' However, data on the socio-economic  
41 status of the ties would be desirable in order to describe the social composition of the  
42 networks. This way, one could examine if socio-economic variables are bridged in addition to  
43 ethnicity, and refine the results related to the resource argument. A second limitation that has  
44 to be mentioned is that only strong(er) inter-ethnic ties are measured. One therefore does not  
45

1  
2  
3 know whether the results are the same for people's entire network. Further research is  
4  
5 needed that can also include people's weak ties.  
6

7 As hypothesized, bonding social capital is not associated with occupational status.  
8  
9 Contrary to the expectations, however, also with regard to employment, immigrants in  
10  
11 Germany do not profit from co-ethnic and family-based social capital. This supports the  
12  
13 'isolation' rather than the 'closure' argument: closure may indicate a high level of solidarity  
14  
15 and enforceable trust, but it does not result in valuable information or support that is useful in  
16  
17 finding a job. Since people in the sample are dominantly long-term immigrants, an alternative  
18  
19 explanation might be the ongoing incorporation of immigrants in German society. Sanders  
20  
21 (2002, p. 348) concludes: 'When social boundaries take on less of a gate- keeper function  
22  
23 protecting ethnically generated resources and more of a bridging function encouraging  
24  
25 greater intergroup association, the identity-preserving influence of ethnic boundaries is likely  
26  
27 to decline'. Also Hagan (1998) concludes that, especially shortly after arrival, family-based  
28  
29 and co-ethnic networks offer the resources needed to find jobs. Since the sample consists  
30  
31 mostly of long term-migrants, it could hence be that bonding social capital did have its value  
32  
33 in the past, but is no longer relevant after a substantial number of years in the host society.  
34

35 Keeping in mind the conceptualization of bonding and bridging social capital, as well as  
36  
37 the limitations of the data, it seems that in the case of male immigrants in Germany, whereas  
38  
39 bridging is to get ahead, bonding is indeed to get by.

## 52 Notes

53  
54  
55 <sup>i</sup> Immigrants are either included in the "foreigner" sample, (started in 1984, consisting of Turks,  
56 Yugoslavians, Greeks, Italians and Spanish), in the "immigrant sample" (started in 1994/1995,  
57 consisting of households in which at least one member moved from abroad to Germany), or in  
58 the "refreshment" sample (1998 and 2000).

---

ii The attrition rate is most likely lower because only the working age population is included.

iii Persons with a German nationality were not included because the construct “visiting Germans at home” was not asked in all waves to people with a German nationality. Furthermore, they were not included to make sure that the ties mentioned are measured as bridging and bonding in the same way for the whole sample.

iv. This classification effectively separates native Germans and ethnic minorities. In one case it is less clear. Ties that belong to the second generation *and* have German citizenship could be classified as either ‘from another country or as ‘from the old/new Federal states’. In the follow-up question (‘Do you come from the same country [as the person mentioned]’), it appeared that in 98% of the cases people indicate them to be from the same country as they are themselves (for people born in Germany but no German citizenship, this percentage is 93). That is, the country referred to is the country of origin. This is most likely the same when immigrants classify ties that belong to the second generation and with a German nationality.

v The categories are slightly collapsed: included are inadequately/general elementary (originally separate categories), basic vocational, intermediate vocational/general (originally separate categories), general or vocational maturity certificate and tertiary education. Models were also estimated including parental education. This did not yield different results.

vi Cronbach’s alpha ranging from .83 to .86 across waves.

vii Due to the low N in some of the states several categories are collapsed: Mecklenburg-Western Pomerania, Brandenburg, Saxony, Saxony-Anhalt and Thuringia are collapsed in one category.

viii However, the Hausman test favours the FE model. Furthermore, the standard errors of the FE model are robust.
