HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract—Emerging technologies for marine current turbines are mainly related to works that have been carried out on wind turbines and ship propellers. It is then obvious that many electric generator topologies could be used for marine current turbines. As in the wind turbine context, doubly-fed induction generators and permanent magnet generators seem to be attractive solutions for harnessing the tidal current energy. In this paper, a comparative study between these two generator types is presented and fully analyzed in terms of generated power, maintenance, and operation constraints. This comparison is done for the Raz de Sein site (Brittany, France) using a multiphysics modeling simulation tool. This tool integrates, in a modular environment, the resource model, the turbine hydrodynamic model, and generator models. Experiments have also been carried out to confirm the simulation results.

Index Terms—Control, doubly-fed induction generator, marine current turbine, modeling, permanent magnet synchronous generator.

I. INTRODUCTION

Considering the main projects for harnessing tidal energy, it can be noticed that many technological solutions have been proposed and tested to find the optimal ones [1]. Therefore, it is necessary to develop simulation environments to estimate marine current turbine global behavior and potential energy capture from the various sites. For that purpose, the authors have previously elaborated on such an environment [2], [3]. Indeed, this tool associates the resource model, the hydrodynamic turbine model, and electrical generator models in a multiphysics approach. These models are integrated in the Matlab-Simulink® environment as Simulink blocks. This method allows a good modularity of the simulator. Therefore, this MCT simulator is very useful for estimating the relevance of a technological solution for a given site [4].

In this paper, this MCT simulator is used to estimate the harnessed power from a DFIG- and PMSG-based MCT. To highlight differences between the considered technologies, a variable-speed control approach based on an MPPT strategy is used to carry out simulations and experiments. The two technology choices are then fully analyzed in terms of generated power, maintenance, and operating constraints.

II. MARINE CURRENT TURBINE MODELING

The global scheme for a grid-connected marine current turbine is given by Fig. 1. Considering this scheme, it can be no-

NOMENCLATURE

MCT  Marine current turbine.
DFIG  Doubly-fed induction generator.
PMSG  Permanent magnet synchronous generator.
MPPT  Maximum power point tracking.
\( \rho \)  Fluid density (kg/m\(^3\)).
\( A \)  Cross-sectional area of the marine turbine (m\(^2\)).
\( V_{\text{tide}} \)  Fluid speed (m/s).
\( \lambda \)  Tip speed ratio.
\( C_p \)  Power coefficient.
\( C \)  Torque coefficient.
\( s_r \)  Spring (neap) tide current speed (m/s).
\( \sigma \)  Total leakage coefficient, \( \sigma = 1 - M^2 / L_s L_r \).
\( \theta_r \)  Rotor position (rad).
\( \omega_r (\omega_s) \)  Angular speed (synchronous speed) (rad/s or r/min).
\( f \)  Viscosity coefficient (Nm/s).
\( J \)  Rotor Inertia (kg-m\(^2\)).
\( p \)  Pole pair number.

\( d, q \)  Synchronous reference frame index.
\( V(I) \)  Voltage (V) [current (A)].
\( P(Q) \)  Active (reactive) power (W).
\( \phi \)  Flux (Wb).
\( T_{\text{em}}(T_m) \)  Electromagnetic torque (mechanical torque) (Nm).
\( R \)  Resistance (\( \Omega \)).
\( L(M) \)  Inductance (mutual inductance) (H).
\( \sigma \)  Total leakage coefficient, \( \sigma = 1 - M^2 / L_s L_r \).
\( \theta_r \)  Rotor position (rad).
\( \omega_r (\omega_s) \)  Angular speed (synchronous speed) (rad/s or r/min).
\( f \)  Viscosity coefficient (Nm/s).
\( J \)  Rotor Inertia (kg-m\(^2\)).
\( p \)  Pole pair number.
noticed that a global multiphysics approach must be considered to study the behavior of an MCT. So a simulation tool able to predict the behavior of such a system must comprise the resource, the hydrodynamic turbine, the generator, the drive, and grid connection models [2], [3].

A. The Resource Model

1) Resource Potential: The total kinetic power in a marine current turbine has a similar dependence to that of a wind turbine and is governed by [5]

\[ P = \frac{1}{2} \rho AV_{\text{tides}}^3, \]  

(1)

However, an MCT can only harness a fraction of this power due to losses, and (1) is modified as follows:

\[ P = \frac{1}{2} \rho C_p AV_{\text{tides}}^3, \]  

(2)

For MCTs, \( C_p \) is estimated to be in the range 0.35–0.5 [1]. Thus, the extracted power depends mainly on the tidal velocities and the turbine sizes (Fig. 2).

2) Resource Model: Tidal current data are given by the French Navy Hydrographic and Oceanographic Service at hourly intervals starting at 6 h before high waters and ending 6 h after. Therefore, knowing the tide coefficient \( (C) \), a simple

\[ V_{\text{tides}} = V_{\text{at}} + \frac{(C - 45)(V_{\text{st}} - V_{\text{nt}})}{95 - 45} \]  

(3)

where 95 and 45 are, respectively, the spring and neap tide medium coefficients.

It can be noticed that an MCT experiences less perturbations than wind turbine because they are immersed systems. For MCTs, the main perturbation is the swell effect. Nevertheless, this study is limited to normal operating conditions and does not include swell and other disturbance effects which were previously presented and analyzed in [6].
This first-order model (3) is then used to calculate the tidal velocity each hour. The implemented model will allow the user to compute tidal velocities in a predefined time range (Fig. 3) [3].

B. The Turbine Rotor Model

The blade element momentum (BEM) method has been used for the marine turbine rotor modeling [7]. Fig. 4 shows some performance results obtained with this method for a 1.44-m diameter three-blade rotor [2]. The studied turbine is an open flow (nonducted) classical horizontal axis one.

C. The Generator Model

Much of the technology that has been suggested for tidal current energy extraction is reminiscent of that used for wind applications. It is then obvious that some wind electric generator topologies could be used for marine turbines [1]. Table I briefly summarizes the pros and cons of the major generator topologies. In this table, many topologies seem a priori to be exploitable for tidal turbines.

In this paper, we chose to focus on two of these generator technologies. The first one is the DFIG which is extensively used for wind turbines [8], [9].

This system, which is one of the main adopted technologies for wind turbines, results in lower converter costs and lower power losses compared to a system based on a fully-fed synchronous generator with full-rated converter. Nevertheless, this generator has two main drawbacks: the limited speed range and the need for regular maintenance even if the DFIG is considered a robust system [10].

The second one is the PMSG. It was chosen because this technology is characterized by a low maintenance level and high compactness, and allows using nonconventional solutions for the turbine generator integration [11]–[16]. These points appear to be particularly suitable in the marine context. Other technologies appear not to be very suitable for MCTs due to the cons summarized in Table I.

1) DFIG Model: The DFIG offers several advantages including variable-speed operation, and four-quadrant active and reactive power capabilities [10], [17]. Such a system also results in lower converter costs and lower power electronics losses compared to a system based on a fully-fed synchronous generator with full-rated converter.

The control system is usually defined in the synchronous $d-q$ frame fixed to either the stator voltage or the stator flux [17]. The generator dynamic model written in a synchronously rotating frame $d-q$ is given by (a schematic diagram of a DFIG-based generation system is shown in Fig. 5)

\[
\begin{align*}
\frac{d\phi_{ds}}{dt} &= V_{ds} + R_s I_{ds} + \omega_s \phi_{qs} \\
\frac{d\phi_{qs}}{dt} &= -V_{qs} + R_s I_{qs} - \omega_s \phi_{ds} \\
\frac{d\phi_{dr}}{dt} &= V_{dr} + R_r I_{dr} + \omega_r \phi_{qr} \\
\frac{d\phi_{qr}}{dt} &= V_{qr} + R_r I_{qr} - \omega_r \phi_{dr} \\
\phi_{ds} &= -L_s I_{ds} - M I_{dr} \\
\phi_{qs} &= -L_s I_{qs} - M I_{qr} \\
\phi_{dr} &= -L_r I_{dr} - M I_{ds} \\
\phi_{qr} &= -L_r I_{qr} - M I_{qs} \\
T_{em} &= p M (I_{qs} I_{dr} - I_{ds} I_{qr}) \\
J \frac{d\omega}{dt} &= T_{em} - T_m - f \omega.
\end{align*}
\] (4)

2) PMSG Model: The PMSG choice allows direct-drive systems that avoid gearbox use [11]–[13], [16]. This solution is very advantageous as it leads to low maintenance constraints. However, in such design, the generator is completely decoupled from the grid by a voltage source full power converter (AC/DC/AC) connected to the stator (Fig. 6).

The PMSG dynamic equations are expressed in the synchronously rotating $d-q$ reference frame. The electrical dynamics model in terms of voltage and current can be given as [2]

\[
\begin{align*}
V_d &= R I_d + L_d \frac{dI_d}{dt} - \omega L_q I_q \\
V_q &= R I_q + L_q \frac{dI_q}{dt} + \omega L_d I_d - \omega \phi_f.
\end{align*}
\] (5)

The electromagnetic torque in the rotor is written as

\[
T_{em} = \frac{3}{2} p [L_d I_q - L_q I_d - \phi_f I_q].
\] (6)
III. MARINE CURRENT TURBINE VARIABLE-SPEED CONTROL

To illustrate the variable-speed control, a low-power variable-speed fixed-pitch MCT-driven DFIG and PMSG have been simulated. The proposed variable-speed control strategy is based on an MPPT. First, the optimal speed reference $\omega_{\text{ref}}$ at each time is computed from the tidal velocity knowledge. This speed reference corresponds to the maximum power which can be mechanically extracted by the turbine for the fluid velocity value. Then, classical speed control of the generator ensures that the rotors speed converges to $\omega_{\text{ref}}$ based on PI control. The above proposed control strategy for a DFIG-based MCT is illustrated in Fig. 7.

For speed references given by the MPPT strategy, the DFIG-based MCT control performance is shown in Figs. 8 and 9, respectively, illustrating the rotor speed tracking performance and the generated active power.

The simulation time has been reduced to seconds to limit the computation time to realistic ones. In real-world application, the system mechanical dynamics will be slower than in simulations. Therefore, the MCT inertia was reduced in simulations to take into account the reduced calculation time. The variable-speed control strategy is tested by using a resource first-order model for a marine current turbine of 1.44-m diameter and 7.5-kW DFIG. This low power corresponds to the test model used for experimental validation in Section IV.

The main merit of the DFIG is its capability to deliver constant voltage and frequency output for $\pm 30\%$ speed variation around conventional synchronous speed. It is also possible to extend the speed variation range from $30\%$ to $50\%$, however this requires a larger power converter.

The same variable-speed strategy has been adopted for the PMSG-based MCT control. The obtained results show good
tracking performance for the PMSG rotor speed (Fig. 10). Fig. 11 illustrates the generated active power. While real-world applications might take advantage of a direct-drive PMSG, the simulations presented here use a geared PMSG to be able to compare them with experimental data. Indeed, experiments were carried out in a test bench using a geared PMSG driven by a DC motor that emulates hydrodynamic loads as shown in Section IV [2]. This geared PMSG is able to follow the MPPT in all the speed range. Therefore, as a first approach, it will have the same behavior as the direct-drive system in terms of harnessed energy (excluding the supplementary losses introduced by the gearbox).

In the two cases there are minor differences between the predicted and simulated power. These differences are mainly due to the type of control which is based on speed control and not on a direct power control.

It can be noticed that the harnessed global power is bigger with a PMSG-based MCT than with a DFIG-based one. This is mainly due to the limited speed range of the system. Indeed, the DFIG cannot reach the MPPT strategy required speed for all the tidal velocities. This point will be more detailed in Section V.

IV. EXPERIMENTAL TESTS

A. Experimental Setup

Experiments were carried out on the experimental setup illustrated in Fig. 12 [2]. This setup allows the physical simulation of a marine power system. The MCT is emulated by a DC motor,
which reproduces the torque and the inertia with respect to current tidal speeds and the turbine rotational speed. The DC motor is first connected to a 7.5-kW DFIG [Fig. 12(a)] and then connected to a 7.5-kW PMSG [Fig. 12(b)]. Ratings of test equipment are given in Appendixes I–III.

B. Experimental Tests

The experimental test conditions were set closely to the simulation conditions for both MCT topologies. For comparison purposes, Figs. 13–16 show simulation and experimental results of the rotor speed tracking performances and the generated power.

Considering real-world marine conditions, the obtained results are satisfactory. It should be noted that the setup is equipped with current and torque limitations that explain some of Figs. 14 and 16 differences, particularly for high power generation.

V. GENERATOR TOPOLOGY COMPARATIVE STUDY

The comparison of different generator systems in the literature is generally discussed with criteria based on the energy yield and cost. In this study, the comparative criterion is the captured energy regarding the MCT topology and the effect of the variable-speed range.

The DFIG appears slightly more advantageous than the PMSG since it is a lightweight and low-cost concept [18], [19].
Indeed, the converter for DFIG-based MCT is dimensioned only for 25% of the rated power, which justifies the success of these systems for wind applications. But the particular context of marine applications imposes different constraints. The marine current turbine will be installed in sites with strong currents and difficult access. Therefore, minimizing maintenance is a fundamental aspect. A direct-drive PMSG requires less maintenance than the DFIG which needs regular maintenance for the gearbox and the slip rings.

For the first criterion, the annual produced power was calculated for the two generator systems based on tidal current data from the Raz de Sein (Brittany, France), using a 10-m diameter and 100-kW turbine. These power ratings correspond to
the major prototypes that have been recently tested [1]. Fig. 17 shows the Raz de Sein site tidal histogram, and Figs. 18 and 19 illustrate the annual power extracted by each generator system for the above MCT rated power.

In this case and for calculation time reasons, simulations are only based on the use of the resource and the turbine hydrodynamic model. This means that the turbine generator speed control is considered to be able to perfectly track the MPPT reference speed. This assumption appears to be realistic considering simulations and experiments in low power cases previously presented in Figs. 14 and 16.

The harnessed power from DFIG-based MCT is estimated to be about 1530 MWh/year. However, the PMSG-based MCT can extract up to 1916 MWh/year. Thus, over a year, there is a difference of about 25% between the two generator systems and this percentage will grow when using a larger turbine. This difference is due to speed restrictions imposed on the DFIG. Indeed, the speed references are limited to ±30% of the rated speed. These limited speeds, when imposed as reference, correspond generally to a poor $C_p$ leading to a reduced extracted power.

VI. CONCLUSION

According to the comparative study based on simulation and experiments, the PMSG-based MCT has the highest energy yield. It can be concluded that, if solutions based on a doubly-fed induction generator have been very successful for wind turbine applications due to the low converter cost, it is probably not the case in marine turbine applications, except in
special cases where regular maintenance is possible. Moreover, PMSG direct drives seem much more applicable for marine applications which require very robust and maintenance-free systems. In this case, the system cost increase is compensated by a higher amount of harnessed energy and lower maintenance constraints.

In this context, the presented study will be further extended to include direct-drive systems. In fact, a rim-driven prototype has been built and its performance will be evaluated and compared to the above classical topologies (Fig. 20).

APPENDIX I
PARAMETERS OF THE SIMULATED AND TESTED DFIG

\[
\begin{align*}
R_s &= 0.455 \, \Omega \\
L_s &= 0.084 \, H \\
R_r &= 0.62 \, \Omega \\
L_r &= 0.081 \, H \\
M &= 0.078 \, H \\
J &= 0.3125 \, kg \cdot m^2 \\
f &= 6.73 \times 10^{-3} \, Nm^{-1}.
\end{align*}
\]

APPENDIX II
PARAMETERS OF THE SIMULATED AND TESTED PMSG

7.5 kW, 3000 r/min, 22 Nm

\[
\begin{align*}
R &= 0.173 \, m\Omega \\
L_d &= 0.085 \, mH \\
L_q &= 0.951 \, mH \\
\phi_f &= 0.112 \, Wb \\
J &= 0.0048 \, kg \cdot m^2 \\
f &= 8.5 \times 10^{-3} \, Nm^{-1}.
\end{align*}
\]

APPENDIX III
PARAMETERS OF THE DC MOTOR

6.5 kW, 3850 r/min, 310 V, 24.8 A

\[
\begin{align*}
R_s &= 78 \, \Omega \\
R_r &= 0.78 \, \Omega \\
L_r &= 3.6 \, H \\
J &= 0.02 \, kg \cdot m^2.
\end{align*}
