Université d’Avignon et des Pays de Vaucluse, UMR EMMAH, Faculté des Sciences, 33 rue Louis Pasteur, F-84914 Avignon, France

Abstract

This paper deals with the study of axisymmetric wave propagation in various acoustic / porous stratified media coupling configurations. It presents the theoretical developments of a semi-analytical method, its validation for a limit test-case half-space ground, and an extension to a realistic multilayered seabed, when spherical waves are emitted from a transient point source in water.

Keywords: Stratified poroelastic seabed, Spherical acoustic wave, Axisymmetric geometry, Hankel-Fourier transforms.

1. Introduction

The study of wave propagation in seawater-seabed coupling configurations is of interest for underwater acoustics and civil engineering [1, 2, 3]. On the one hand, the acoustic equation models the physical phenomenon in the seawater part, and on the other hand, the Biot equations describe the seabed.
part [4, 5]. In such problems, several boundary conditions between the fluid and the top porous layer can be used to model hydraulic exchanges [1, 6, 7].

The proposed study focuses on transient wave propagation in a multi-region medium composed of a fluid half-space representing seawater over a stratified poroelastic medium representing the seabed. The source is located within the seawater part and emits spherical transient waves. The purpose is to provide a semi-analytical approach to solve this coupled problem in an axisymmetric configuration.

Configurations are often restricted to 2D Cartesian geometries. Three-dimensional Green’s function in axisymmetric configurations was first developed by [8] for an acoustic point source located near a half-space poroelastic seabed. Nevertheless, the study was restricted to half-space situations.

Focusing on the stratified aspect of the problem, the strategies usually adopted are based on transfer matrix, stiffness matrix or transmission and reflexion matrix methods. The main difficulty deals with the conditioning of matrices, that can be overcome using specific techniques [9]. These methods historically developed for electromagnetic and then viscoelastic problems have been extended to poroelastic media. These developments have been proposed for 2D Cartesian geometries with a free surface [9, 10] and then with a coupling with a seawater interaction [11]. In the present article, we propose to extend the previous work to an axisymmetric geometry and to couple the stratified poroelastic medium to a fluid one. Thus, this work can be used as benchmark solutions for numerical approaches, or for comparisons with experimental results. Moreover it represents the first step of the Boundary Element Method. The axisymmetric approach is based on Hankel-Fourier
transforms, providing thus an analytical matrix system for the fluid pressure
stresses / displacements / velocities in the frequency-wavenumber domain.
To obtain results in the time and space domain, integrations are then per-
formed numerically.

The paper is organized as follows. Section 2 describes the geometry under
study, and proposes analytical solutions to the acoustic equation and Biot
equations in the context of multilayered medium and axisymmetric geometry.
Section 3 presents a test case to validate the results by a comparison with
those of [8], and illustrates both the stratified aspect of the ground and the
interface with the seawater.

2. Model formulation

2.1. Geometry under study

The configuration under investigation is a fluid half-space Ω₀ over a stack
of homogeneous and isotropic poroelastic layers Ωₙ (n = 1, ⋯, N), as shown
in Fig. 1. The z geometrical axis points upward. The N plane and parallel
interfaces are located at zₙ ≤ 0, with z₀ = 0. An acoustic point source
Oₛ (rₛ = 0 ; zₛ > 0) in the fluid emits transient spherical waves.

2.2. Multilayered porous medium

The poroelastic media are modeled using the Biot theory [1, 4, 5]. For
homogeneous and isotropic layers, the physical parameters do not depend
on the spatial coordinates and can be listed as follows: for the saturating
fluid, dynamic viscosity η and density ρₐ; for the elastic skeleton, density ρₛ
and shear modulus μ as well as connected porosity φ, tortuosity α, absolute
permeability $\kappa$, Lamé coefficient of the dry matrix $\lambda$, and two Biot coefficients $\beta$ and $m$. Based on the constitutive equations and the conservation of momentum in porous media, one obtains

\[
\begin{align*}
\sigma & = (\lambda \nabla \cdot \mathbf{u} - \beta p) I + 2 \mu \varepsilon, \quad (1a) \\
p & = -m (\beta \nabla \cdot \mathbf{u} + \nabla \cdot \mathbf{w}), \quad (1b) \\
\nabla \sigma & = \rho \ddot{\mathbf{u}} + \rho_f \ddot{\mathbf{w}}, \quad (1c) \\
-\nabla p & = \rho_f \ddot{\mathbf{u}} + \frac{a \rho_f}{\phi} \dot{\mathbf{w}} + \frac{\eta}{\kappa} \Upsilon * \dot{\mathbf{w}}, \quad (1d)
\end{align*}
\]

where $\mathbf{u}$, $\mathbf{U}$ and $\mathbf{w} = \phi (\mathbf{U} - \mathbf{u})$ are the solid displacement, the fluid displacement and the relative displacement vectors, respectively. $I$ is the identity tensor, $\sigma$ is the stress tensor, $\varepsilon = 1/2 (\nabla \mathbf{u} + \nabla^T \mathbf{u})$ is the strain tensor, and $p$ is the pore pressure. $\rho = \phi \rho_f + (1 - \phi) \rho_s$ is the total density. The overlying dot denotes the derivative in terms of time $t$. $*$ stands for a convolution product in time. The quantity $\frac{\eta}{\kappa} \Upsilon * \dot{\mathbf{w}}$ corresponds to the time domain drag force between the porous skeleton and the pore fluid [12, 13]. Expression for $\Upsilon * \dot{\mathbf{w}}$ depends on the frequency range involved. In the low-frequency range, the relative motion between the fluid and the porous skeleton is of Poiseuille type, and then the expression is given by

\[
\Upsilon(t) = \delta(t) \Leftrightarrow \Upsilon(t) * \dot{\mathbf{w}}(t) = \dot{\mathbf{w}}(t)
\]

In the high-frequency range, the relative motion between the fluid and the porous skeleton is dominated by the inertial effects. We adopt here the well-known model proposed by [14] and written in the frequency domain. The expression in the time domain is given in [13, 15] with the following form for
the convolution product

\[ \Upsilon(t) \ast \mathbf{\dot{w}}(t) = \frac{1}{\sqrt{\Omega}}(D + \Omega)^{1/2}\mathbf{\dot{w}}(t) \]

where \( \Omega = \frac{\omega_{\text{JKD}}}{\chi} \) with \( \omega_{\text{JKD}} = \frac{\eta\phi}{\alpha \rho f} \) the transition radial frequency between the low- and high-frequency ranges. \( \chi \) is the Pride number. The operator \( (D + \Omega)^{1/2} \) is a shifted order 1/2 fractional derivative. Note that the drag force depends on the entire history of \( \mathbf{\dot{w}}(t) \).

Pressure and stress components are eliminated from Eqs. (1a)-(1b) and substituted in Eqs. (1c)-(1d), giving a \((u, w)\) second-order wave formulation [9, 10]. By introducing the Helmholtz potentials for the solid \((\varphi, \Psi)\) and relative \((\varphi^r, \Psi^r)\) displacements, the wave formulation yields a system of partial differential equations associated to these potentials as follows

\[ \begin{align*}
-\mu (\Delta \psi_\theta - \frac{\psi_\theta}{r^2}) + ((1 - \phi) \rho_s + \phi \rho_t) \ddot{\psi}_\theta + \rho_t \dot{\psi}_\theta^0 &= 0, \\
\rho_t \ddot{\psi}_\theta + \frac{a \rho_t}{\phi} \dot{\psi}_\theta^0 + \frac{\eta}{\kappa \sqrt{\Omega}} (D + \Omega)^{1/2} \dot{\psi}_\theta^r &= 0, \\
(\lambda + 2\mu + m \beta^2) \Delta \varphi + m \beta \Delta \varphi^r - \rho^r \dot{\varphi} - \rho_e \ddot{\varphi} &= 0, \\
m \beta \Delta \varphi + m \Delta \varphi^r - \rho_t \ddot{\varphi}^r - \frac{a \rho_t}{\phi} \dot{\varphi}^r - \frac{\eta}{\kappa \sqrt{\Omega}} (D + \Omega)^{1/2} \dot{\varphi}^r &= 0.
\end{align*} \]

Note that when projecting in the axisymmetric geometry, only the \( \theta \) coordinate is useful for the vector potentials: \( \Psi = \psi_\theta(r, z, t) e_\theta \).

For an axisymmetric configuration, it is relevant to introduce the \( n \)th order Hankel (or Fourier-Bessel) transform over the \( r \) variable, and the Fourier transform over the \( t \) variable, of an integrable function \( f \), defined as follows [16]

\[ \tilde{f}_n(\xi) = \int_0^{+\infty} rf(r)J_n(\xi r)dr \quad \text{and} \quad f^*(\omega) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} f(t)e^{i\omega t}dt, \]
where $\xi$ is the transform Hankel parameter, $\omega$ the radial frequency and $J_n$ the $n$th order Bessel function of the first kind.

In the following, we perform a Fourier transform in time of Eqs. (2a)-(2b)-(2c)-(2d). Then, 0th- and 1st-order Hankel transforms are applied to the scalar and vector potentials, respectively. From equation (2b), a proportionality relation between $\tilde{\psi}^*_{\theta 1}(\xi, \omega)$ and $\tilde{\psi}^*_{\theta 1}(\xi, \omega)$ is obtained

$$\tilde{\psi}^*_{\theta 1}(\xi, \omega) = \frac{\rho I \omega}{\phi} + i\frac{\eta I \omega}{\kappa} \tilde{\psi}^*_{\theta 1}(\xi, \omega) = G^*(\omega) \tilde{\psi}^*_{\theta 1}(\xi, \omega). \quad (4)$$

Then, the introduction of the above relation in the doubly transformed domain formulation of Eq. (2a) provides the partial differential equation relative to the S shear wave

$$\frac{\partial^2 \tilde{\psi}^*_{\theta 1}}{\partial z^2}(\xi, \omega) + \left(\frac{\omega^2}{\mu}(1 - \phi)\rho_s + (\phi + G^*(\omega)\rho_I) - \xi^2\right) \tilde{\psi}^*_{\theta 1}(\xi, \omega) = 0. \quad (5)$$

Similarly, relative and absolute scalar potentials are linked by

$$\tilde{\varphi}^*_{0j}(\xi, \omega) = \frac{\rho I \omega^2 - m \beta (k_{Fj}^2 + \xi^2)}{m (k_{Fj}^2 + \xi^2) - \frac{\rho I \omega^2}{\phi} - i\frac{\eta I \omega}{\kappa} T^*(\omega)} \tilde{\varphi}^*_{0j}(\xi, \omega) = F_j^*(\xi, \omega) \tilde{\varphi}^*_{0j}(\xi, \omega), \quad (6)$$

where $j = 1, 2$. The formulation of Eqs. (2c) and (2d) in the doubly transformed domain results in two coupled partial differential equations relative to the $P_1$ and $P_2$ compressional waves, defined as

$$\left[\left(\frac{\partial^2}{\partial z^2} - \xi^2\right) K + \omega^2 M + i\omega C\right] \tilde{\Phi}^* = 0, \quad (7)$$

where $\tilde{\Phi}^* = \left\{\tilde{\varphi}^*_{0j}(\xi, \omega), \tilde{\varphi}^*_{0j}(\xi, \omega)\right\}$, stiffness, mass and damping matrices being
respectively

\[ K_P = \begin{bmatrix} \lambda + 2\mu + m\beta^2 & m\beta \\ m\beta & m \end{bmatrix}, \quad M = \begin{bmatrix} \rho & \rho_f \\ \rho_f & \frac{a\rho_f}{\phi} \end{bmatrix}, \quad C = \begin{bmatrix} 0 & 0 \\ 0 & \frac{\eta}{\kappa} \mathcal{Y}^*(\omega) \end{bmatrix}. \]

(8)

From Eqs. (5) and (7), we introduce global wavenumbers \( k_S \) and \( k_{Pj} \) by the relations

\[ k^2_S = k_{zS}^2 + \xi^2 = \omega^2 \mu ((1 - \phi)\rho_s + (\phi + G^*(\omega)\rho_f)) \]

and

\[ k^2_{Pj} = k_{zP}^2 + \xi^2. \]

\( k_{zS}, k_{zPj} \) and \( \xi \) are the associated vertical wavenumbers and the radial wavenumber, respectively. Applying the Fourier transform over the \( z \) variable defined as follows

\[ \mathcal{F}(k_z) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} f(z)e^{-ik_zz}dz \]

(9)

to system (7), yields the dispersion relation when the determinant of matrix is equal to zero. Then, the general solution relative to the solid phase Helmholtz potentials of system (5)-(7) can be written as

\[ \tilde{\psi}_1^*(\xi, z, \omega) = \tilde{\psi}^I_{01}(\xi, \omega)e^{-ik_{zS}z} + \tilde{\psi}^R_{01}(\xi, \omega)e^{ik_{zS}z}, \]

(10)

\[ \tilde{\varphi}_0^*(\xi, z, \omega) = \tilde{\varphi}^I_{02}(\xi, \omega)e^{-ik_{zP}z} + \tilde{\varphi}^R_{02}(\xi, \omega)e^{ik_{zP}z} + \tilde{\varphi}^*_0(\xi, \omega)e^{-ik_{zP}z} + \tilde{\varphi}^*_0(\xi, \omega)e^{ik_{zP}z}, \]

(11)

where I and R state the ‘incident’ (or downward) and the ‘reflected’ (or upward) waves, respectively.

The choice of an upward (z) axis, implies that the conditions \( \Im m\{k_{zS}\} \geq 0 \) as well as \( \Im m\{k_{zPj}\} \geq 0 \) \((j = 1, 2)\) should be satisfied to have a bounded field far away from the ground surface \((z \rightarrow -\infty)\).

Besides, for an axisymmetric geometry

\[ \tilde{u}_r^1(\xi, z, \omega) = -\xi \tilde{\varphi}_0^*(\xi, z, \omega) - \frac{\partial \tilde{\psi}_0}{\partial z}(\xi, z, \omega), \]

(12)
\[
\tilde{u}^*_0(\xi, z, \omega) = \frac{\partial \tilde{\phi}^*_0}{\partial z}(\xi, z, \omega) + \xi \tilde{\psi}_1^*(\xi, z, \omega). \tag{13}
\]

Obviously, analogous expressions are obtained for the radial and vertical relative displacement components of vector \(\mathbf{w}\) by substituting Helmholtz potentials for the solid displacement by relative ones.

Then, the expressions of \(\tilde{u}^*_r\) and \(\tilde{u}^*_z\) as functions of the scalar ‘incident’ and ‘reflected’ Helmholtz potentials, are obtained from Eqs. (10)-(11) substituted in Eqs. (12)-(13). The same developments are performed for \(\tilde{w}^*_r\) and \(\tilde{w}^*_z\) with relative Helmholtz potentials. In the present axisymmetric configuration, the exact stiffness matrix approach is based on vectors of transformed displacement and stress components \([9, 10]\), defined as

\[
\tilde{\mathbf{u}}^* = (\tilde{u}^*_r, i \tilde{u}^*_z, i \tilde{w}^*_z)^t, \quad \tilde{\mathbf{\Sigma}}^* = (\sigma^*_{r1}, i \sigma^*_{z2}, -i \tilde{p}^*_0)^t.
\]

By using matrix notations, after setting \(\tilde{\Phi}^*_{I/R} = (\tilde{\phi}^*_{I/R}^1, \tilde{\phi}^*_{I/R}^2, \psi_{I/R}^1)^t\), one can deduce

\[
\begin{pmatrix}
\tilde{\mathbf{u}}^*(\xi, z_n-1, \omega) \\
\tilde{\mathbf{u}}^*(\xi, z_n, \omega)
\end{pmatrix} =
\begin{bmatrix}
\text{Mat}^I & \text{Mat}^{RZ} \\
\text{Mat}^IZ & \text{Mat}^R
\end{bmatrix}
\begin{pmatrix}
\tilde{\Phi}^*_{I}(\xi, \omega) \\
\tilde{\Phi}^*_{R}(\xi, \omega)
\end{pmatrix}, \tag{14}
\]

where \(\tilde{\Phi}^*_{I/R}\) are modified potentials to have a better conditioning of Eq. (14) \([9]\). \(\text{Mat}^{I/R} = \left[ \text{mat}^{I/R}_{pq} \right] \); \(p = 1, 2, 3 \); \(q = 1, 2, 3\) with

\[
\begin{cases}
\text{mat}^{I/R}_{11} = \text{mat}^{I/R}_{12} = -\xi; & \text{mat}^{I/R}_{13} = -\text{mat}^{R}_{13} = +ik_{z2}; \\
\text{mat}^{I}_{21} = -\text{mat}^{R}_{21} = +k_{zp1}; & \text{mat}^{I}_{22} = -\text{mat}^{R}_{22} = +k_{zp2}; \\
\text{mat}^{I/R}_{23} = +i\xi; & \text{mat}^{I}_{31} = -\text{mat}^{R}_{31} = +k_{zp1}\tilde{F}_1^*(\xi, \omega); \\
\text{mat}^{I}_{32} = -\text{mat}^{R}_{32} = +k_{zp2}\tilde{F}_2^*(\xi, \omega); & \text{mat}^{I/R}_{33} = +i\xi G^*(\omega).
\end{cases}
\]
\[ Z = \text{Diag}[e^{ik_1h_n}, e^{ik_2h_n}, e^{ik_3h_n}] \]

where Diag represents the terms of a diagonal matrix. \( h_n = z_{n-1} - z_n > 0 \) is the height of a specific layer “n” bordered by the upper and the lower depth coordinates, \( z_{n-1} \) and \( z_n \), respectively.

Using the Biot behaviour law, stress components can be expressed in terms of transformed displacements

\[
\tilde{\sigma}_{zz}^*(\xi, z, \omega) = \begin{pmatrix}
\tilde{w}_{r1}^*(\xi, z, \omega) + m \beta \tilde{w}_{z0}^*(\xi, z, \omega) \\
\lambda + 2 \mu + m \beta^2 + m \beta \tilde{w}_{r1}^*(\xi, z, \omega)
\end{pmatrix}
\]

Besides, regarding the pore pressure, the equivalent of Eq. (1b) in the doubly transformed domain is

\[
\tilde{p}_0^*(\xi, z, \omega) = -m \left\{ \beta \left[ \xi \tilde{u}_{r1}^*(\xi, z, \omega) + \frac{\partial \tilde{u}_{z0}^*}{\partial z}(\xi, z, \omega) \right] + \xi \tilde{w}_{r1}^*(\xi, z, \omega) + \frac{\partial \tilde{w}_{z0}^*}{\partial z}(\xi, z, \omega) \right\}.
\]

Then, the relation between stresses and Helmholtz potentials is given by

\[
\begin{cases}
\tilde{\Sigma}^*(\xi, z_n, \omega) = S^I S^R Z \begin{pmatrix}
\tilde{\Phi}^I & \tilde{\Phi}^R \\
\end{pmatrix}
\end{cases}
\]

where \( S^{I/R} = \left[ \begin{smallmatrix} s_{pq}^{I/R} \end{smallmatrix} \right] \); \( p = 1, 2, 3 \); \( q = 1, 2, 3 \) with
Finally, analytical expressions for transformed displacement vectors are written in condensed form as

\[
\begin{bmatrix}
T_{\text{layer}}_{n}\end{bmatrix}_{6\times6} = \begin{bmatrix}
\tilde{u}^*(\xi, z_{n-1}, \omega) \\
\tilde{u}^*(\xi, z_n, \omega)
\end{bmatrix} = \begin{bmatrix}
\tilde{\Sigma}^*(\xi, z_{n-1}, \omega) \\
-\tilde{\Sigma}^*(\xi, z_n, \omega)
\end{bmatrix}
\]

(19)

A conventional assembling technique between the layers is then performed [17, 18]. As \([T_{\text{layer}}_{n}]\) is a 6 \times 6 matrix, the global resulting matrix system has dimension 3(N + 1) \times 3(N + 1).

2.3. Acoustic medium

This part presents the analytical model formulation of wave propagation coming from an acoustic point source applied at \(O_s\) (Fig. 1), in the water semi-infinite domain \(\Omega_0\), characterized by celerity of waves \(c\) and by density \(\rho_t\), assumed to be the same as in the porous media \(\Omega_n\).

The acoustic equations are written as follows

\[
\begin{align}
\ddot{U}(r, z, t) &= -\frac{1}{\rho_t} \nabla p(r, z, t), \\
\Delta p(r, z, t) - \frac{1}{c^2} \ddot{p}(r, z, t) &= -s(r, z, t) = -S(t) \delta(r - r_s) \delta(z - z_s)
\end{align}
\]
where \( p \) is the acoustic pressure, \( U \) is the fluid displacement and \( s(r, z, t) \) is the impulse transient superpressure emitted from point \( O_s \). \( S(t) \) is a causal source term and \( \delta \) is the Dirac function.

In the following, we introduce the fluid global wavenumber \( k_f \), linked to its vertical \( (k_{zf}) \) and radial \( (\xi) \) components by \( k_{zf}^2 = k_z^2 + \xi^2 = \frac{\omega^2}{c^2} \), and use the mathematical property

\[
\tilde{\delta}_0(\xi) = \int_{0}^{+\infty} r \delta(r) J_0(\xi r) dr = \frac{1}{2\pi}.
\]  

Then, the partial differential equation relative to the pressure wave is obtained from the formulation of Eq. (20b) in the Fourier and 0th-order Hankel transform domain, as

\[
\frac{\partial^2 \tilde{p}^*_0(\xi, z, \omega)}{\partial z^2} + k_{zf}^2 \tilde{p}^*_0(\xi, z, \omega) = -\frac{S^*(\omega)}{2\pi} \delta(z-z_s). 
\]  

The solution to the above inhomogeneous equation results in the summation of two components:

- the complementary part \( \tilde{p}^*_C(\xi, z, \omega) \) corresponding to the solution of the homogeneous equation associated to Eq. (22),
- the principal part \( \tilde{p}^*_P(\xi, z, \omega) \) which is a specific solution of Eq. (22).

On the one hand, the complementary part of the solution is given by

\[
\tilde{p}^*_C(\xi, z, \omega) = \tilde{P}^*(\xi, \omega) e^{ik_{zf}z} + \tilde{Q}^*(\xi, \omega) e^{-ik_{zf}z},
\]  

\( \tilde{P}^*(\xi, \omega) \) and \( \tilde{Q}^*(\xi, \omega) \) being the amplitudes, \( \tilde{Q}^*(\xi, \omega) = 0 \) and \( \Im(k_{zf}) \geq 0 \) to satisfy the convergence condition when \( z \rightarrow +\infty \).

On the other hand, the calculation of the principal part of the solution is inspired by [19, 20]. Concisely, the key steps are:
(i) Setting the principal part of the solution as a simple Fourier integral expression

\[ \tilde{p}_{P_0}^s(\xi, z, \omega) = \int_{-\infty}^{+\infty} A(\kappa_z) e^{i\kappa_z z} d\kappa_z. \]  

(24)

(ii) Searching function \( A(\kappa_z) \) by introducing Eq. (24) in Eq. (22), multiplying the obtained equation by \( e^{-i\kappa_z z} \) (where \( \kappa_z \in \mathbb{R} \)), integrating over the \( z \) variable from \(-\infty \) to \(+\infty \), and using some mathematical properties of the Dirac function to obtain

\[ A(\kappa_z) = -\frac{S^*(\omega)}{(2\pi)^2} \frac{e^{-i\kappa_z z_s}}{k_{zf}^2 - \kappa_z^2}. \]  

(25)

(iii) Rewriting the principal part of the solution gives

\[ \tilde{p}_{P_0}^s(\xi, z, \omega) = \frac{S^*(\omega)}{(2\pi)^2} I(z - z_s, k_{zf}), \]  

(26)

where [19]

\[ I(z - z_s, k_{zf}) = \int_{-\infty}^{+\infty} e^{i\kappa_z (z - z_s)} \frac{e^{i\pm k_{zf}|z - z_s|}}{k_{zf}^2 - \kappa_z^2} d\kappa_z = \pm i\pi \frac{e^{i\pm k_{zf}|z - z_s|}}{k_{zf}}. \]  

(27)

(iv) Finally obtaining the single physically valid solution, satisfying the Sommerfeld condition [20]

\[ \tilde{p}_{P_0}^s(\xi, z, \omega) = \frac{iS^*(\omega)}{4\pi} \frac{e^{i\pm k_{zf}|z - z_s|}}{k_{zf}}. \]  

(28)

Solution (28) corresponds to the one obtained in [8, 20]. Indeed, these authors provide a Green’s function as a solution of a cylindrical Helmholtz equation, which corresponds to the Fourier transform in time of Eq. (20b). Then, they calculate \( \tilde{p}_{P_0}^s(\xi, z, \omega) \) by using a Sommerfeld integral decomposition of the simply transformed domain solution.
The geometry under study leads to a set of interface equations along the $N$ plane interfaces $z_n$ ($n = 0, \cdots, N - 1$). For this purpose, we denote $[g]_n$ the jump in a function $g$ from $\Omega_n$ to $\Omega_{n+1}$ across $z_n$ as

$$[g]_n = \lim_{\varepsilon \to 0, \varepsilon > 0} g(r, z_n + \varepsilon, t) - \lim_{\varepsilon \to 0, \varepsilon > 0} g(r, z_n - \varepsilon, t) = (g)_n^+ - (g)_n^-.$$  \hfill (29)$$

- The porous / porous interfaces $z_n$ ($n = 1, \cdots, N - 1$) are assumed to be in perfect bonded contact \cite{1}

$$[u_r(r,z,t)]_n = 0, \quad [u_z(r,z,t)]_n = 0, \quad [w_z(r,z,t)]_n = 0,$$
$$[\sigma_{rz}(r,z,t)]_n = 0, \quad [\sigma_{zz}(r,z,t)]_n = 0, \quad [p(r,z,t)]_n = 0. \quad (30)$$

- The fluid / porous interface $z_0 = 0$ is modeled with the following interface conditions \cite{1, 6, 7}

$$\begin{cases} (u_z(r,z,t))_0^- + (w_z(r,z,t))_0^- = (U_z(r,z,t))_0^+, \\
(\sigma_{rz}(r,z,t))_0^- = 0, \quad (31a) \\
(\sigma_{zz}(r,z,t))_0^- = -(p(r,z,t))_0^+, \quad (31b) \\
-[p(r,z,t)]_0 = \frac{1}{K} (\dot{w}_z(r,z,t))_0^-.
\end{cases}$$  \hfill (31d)$$

where $K$ is the hydraulic permeability of the interface. The case $K \to +\infty$ describes open pores. For $K \to 0$, Eq. (31d) is replaced by $(\dot{w}_z(r,z,t))_0^- = 0$, stating sealed pores. An intermediate state for $K \in ]0; +\infty[ \,$ describes imperfect pores.

The formulation of the fluid /porous interface equations (31a)-(31c)-(31d) in the doubly transformed domain enables both to determine the amplitude
\( \tilde{\mathcal{P}}^*(\xi, \omega) \) of the ‘reflected’ pressure wave in the fluid, and as a result to provide the following matrix block

\[
\begin{pmatrix}
-\frac{i \rho f \omega^2}{k_{zf}} & -\frac{i \rho f \omega^2}{k_{zf}} \\
-\frac{i \rho f \omega^2}{k_{zf}} & -\frac{i \rho f \omega^2}{k_{zf}} - \frac{i \omega}{k}
\end{pmatrix}
\begin{pmatrix}
i(\tilde{u}_{z0}^*(\xi, z, \omega))^0_0 \\
i(\tilde{w}_{z0}^*(\xi, z, \omega))^0_0
\end{pmatrix}
= \begin{pmatrix}
-\frac{i \omega}{k} \\
-\frac{i \omega}{k}
\end{pmatrix}
\]

Eq. (32) is assembled to Eq. (19) to give the radial and vertical solid and relative displacements at each interface. The transformed displacements, stresses, velocities and acoustic pressure everywhere inside each domain \( \Omega_n \) can then be obtained analytically. The latter quantities are subsequently calculated in the spatio-temporal domain by means of inverse Hankel-Fourier transforms. For example, the acoustic or pore pressure can be written as follows

\[
p(r, z, t) = \int_0^{+\infty} 2 \Re\left\{ \int_0^{+\infty} \xi \tilde{p}_0^*(\xi, z, \omega) J_0(\xi r) d\xi \right\} e^{-i\omega t} d\omega \tag{33}
\]

The integral over the radial wavenumber, which presents an oscillatory behavior due to factor \( J_0(\xi r) \) and for which the envelope of the maximum amplitudes shows sharp peaks, is performed using an adaptive Filon quadrature, [21, 22]. The adaptive procedure consists in dividing the entire interval into several parts based on what is known about \( \tilde{p}_0^*(\xi, z, \omega) \). Because of the sharp changes in the integrand occurring around the wavenumbers of the propagating waves, the wavenumbers are calculated and sorted out. The quadrature is performed by discretizing finely in their neighborhood and more coarsely
farther away. The integral is truncated depending on the highest wavenumber and adapted to each frequency. As for the numerical processing over $\omega$, the quadrature is done using a Simpson scheme. Numerical values used for the various discretizations are those of [11].

3. Results and discussion

In this section, we propose firstly to validate the above theoretical formulation by using a half-space porous medium such as in [8]. To do that, we consider a limit test-case of the stratified configuration, composed of two layers presenting the same physical properties. Once the semi-analytical approach validated, we present new results coming from a seabed [23, 24] made of ten layers presenting various properties, as an extension of the half-space porous ground.

3.1. Half-space test-case configuration

Porous and fluid parameters are [8]: $\lambda = 10.0 \times 10^9$ Pa, $\mu = 5.0 \times 10^9$ Pa, $\rho_s = 2.5 \times 10^3$ kg.m$^{-3}$, $\rho_f = 1.0 \times 10^3$ kg.m$^{-3}$, $a = 3$, $\beta = 0.7$, $m = 10.0 \times 10^9$ Pa, $\phi = 0.33$, $\eta = 1.0 \times 10^{-3}$ Pa.s, $\kappa = 10^{-8}$ m$^2$ as well as,

$$\Upsilon^*(\omega) = \left(1 + i\frac{\omega}{\Omega}\right)^{1/2}, \quad \Omega = \frac{\eta \phi}{a \kappa \rho_f \chi} \quad \text{with} \quad \chi = 0.5 \text{ [14].}$$

In the water domain $\Omega_0$: $\rho_f = 1.0 \times 10^3$ kg.m$^{-3}$, $c = 1414.0$ m.s$^{-1}$.

The emission point source is located at $z_s = 10$ m and the observation ones are pointed by $r = 20$ m and $z = \pm 20$ m. Such as in [8], $S(t)$ is a Ricker wavelet and $S^*(\omega)$ its Fourier transform

$$S(t) = ((1 - 2\hat{\alpha}^2(t - \hat{\beta})^2)e^{-\hat{\alpha}^2(t - \hat{\beta})^2} \quad \text{and} \quad S^*(\omega) = \frac{\omega^2}{4\hat{\alpha}^3\sqrt{\pi}}e^{i\hat{\beta}^2 - \frac{\omega^2}{4\alpha^2}}, \quad (34)$$
where $\hat{\alpha} = \omega_0/2$ and $\hat{\beta} = t_s$, $\omega_0 = 2\pi f_0$ ($f_0 = 1.0 \times 10^3$ Hz) and $t_s = 2.5 \times 10^{-3}$ s being, respectively the central angular frequency and a shift in time.

As regards time evolution of pore pressure and fluid pressure, Fig. 2 shows that there is an excellent agreement between the results proposed by [8] and those obtained from our calculations. Both in permeable and impermeable cases, it checks the validity of the analytical approach in the half-space limit test-case.

3.2. Extension to a stratified poroelastic seabed

The regarded configuration is built from mechanical data taken from [23, 24]. It corresponds to a more realistic description of a seabed. To model the stratified ground and to illustrate the capabilities of our approach, we have chosen a ten layer geometry coupled to a half-space configuration. In the porous medium, the unchanged parameters are: $a = 1.25$, $\rho_s = 2.65 \times 10^3$ kg.m$^{-3}$ as well as the compressibility of the solid skeleton, $\chi_s = 36$ GPa, and of the fluid volume, $\chi_f = 2$ GPa. The Lamé constants are linked in this study by $\lambda = 2\mu$. Ranges of physical characteristics from the first layer to the half-space are: $\phi \in [0.5 ; 0.2]$, $\kappa \in [10^{-9} ; 10^{-12}]$ m$^2$ and $\mu \in [10^7 ; 10^9]$ Pa. From one stratum to another, only one of these three parameter values is modified as indicated in Tab. 1, as well as the related ones. The two Biot coefficients $\beta$ and $m$ are given by

$$\beta = 1 - \frac{\chi_o}{\chi_s}, \quad m = \frac{\beta - \phi}{\chi_s} + \frac{\phi}{\chi_f},$$

where $\chi_o = \lambda + \frac{2}{3}\mu$.

Parameters relative to the nature of the point source and to the water are the same as for the half-space test-case situation, the only differences are: $z_s = 5$ m and the observation points are located at $r = 1$ m and $z = \pm 1$ cm.
or \( z = -80 \) cm.

</table>

Firstly, Fig. 3 shows very similar time evolutions of fluid pressure at \( z = 1 \) cm observation height, both for sealed, imperfect and open pore interfaces between seawater and seabed. This means that the nature of the contact does not have any influence on the fluid pressure for the configuration under study. Secondly, considering only the impermeable cases, Fig. 3 emphasizes the fact that the properties of the first layer force the fluid
pressure behaviour in the seabed when observation point is very close of the 
$z_0 = 0$ interface. Thirdly, central arrival time of the acoustic compressional 
wave is given by 

$$t_f = \frac{\sqrt{(z_s - z)^2 + r^2}}{c} + t_s = 6.1 \text{ ms}.$$ 

In contrast, Fig. 4 clearly proves that the hydraulic permeability coefficient 
value has a strong impact on temporal variation of the vertical displacement 
at $z = -1 \text{ cm}$ observation height, in the first layer of the seabed. Note 
that this trend is very attenuated when considering stresses in the seabed, 
not shown here.

Besides the comparison between Fig. 4 and Fig. 5 highlights the multiple 
wave reflections at the porous / porous interfaces in the seabed. In addition, 
the confrontation between half-space and multilayered results yields higher 
differences in the intermediate case than those obtained in the extreme situ- 
ations.

In the fourth layer, at $z = -80 \text{ cm}$ observation height (Fig. 6), the nature 
of the contact does not have influence on the first displacement peaks any 
more. This time, the differences due to the kind of hydraulic interface is seen 
on the part of the response relative to the reflection waves ($t > 9 \text{ ms}$).

4. Conclusions

An axisymmetric model of wave propagation in poroelastic / acoustic 
configurations, has been presented, validated and extended by using a semi- 
analytical method. The theoretical development has been based on a matrix
block assembling technique for the porous layers and the fluid domain and takes into account various interface conditions. A half-space porous ground as a limit test-case of our multilayered medium has been considered to validate the analytical model. Indeed, regarding pore and fluid pressures, there is a very good agreement between the results coming from [8] and our calculations, whatever the pore nature. Then, the approach has been applied to a stratified seabed, as an extension of the half-space porous soil, providing new results which emphasize the variations in time of mechanical quantities.

From the obtained displacements and stresses, a future investigation consists in estimating mechanical and hydrological parameters of the systems under study. In parallel, the results could be compared to those issuing from finite difference, element and/or volume approaches or other analytical formulations such as transfer or transmission and reflexion matrices.
