Reactions were performed from aryl azides on the one hand, and activated alkenes coming from β -dicarbonyl compounds or malonodinitrile on the other hand, either with recourse to conventional heating or to microwave activation, to afford 1-aryl-1*H*-1,2,3-triazoles. The mechanism and the regioselectivity of the reactions involving β -dicarbonyl compounds have been theoretically studied using DFT methods at the B3LYP/6-31G* level: they are domino processes comprising a tautomeric equilibrium of the β -dicarbonyl compounds with their enol forms, a 1,3-dipolar cycloaddition of the enol forms with the aryl azides (high activation energy), and a dehydration process (lower activation energy). The effect of non-conventional activation ways on the degradation of 1,2,3-triazolines was next studied experimentally. Finally, some of the 1,2,3-triazoles such synthesized were evaluated for their bactericidal and cytotoxic activities.

Introduction

Cycloaddition reactions are one of the most important synthetic processes, with both synthetic and mechanistic interest in organic chemistry. Among them, 1,3-dipolar cycloadditions (13DCs), whose general concept was introduced by Huisgen and co-workers in 1960s,¹ are versatile tools for building five-membered heterocycles.²

1,2,3-Triazole occupies a special place in heterocyclic chemistry because it is the core structure of many agents of various interests (use as pharmaceuticals, agrochemicals, dyes, corrosion inhibitors, sensors, photostabilizers...), and 13DC between azides and alkynes or enolizable compounds are important ways to generate this heterocycle.³

We focused on the synthesis of 1-aryl-5-methyl-1*H*-1,2,3-triazoles bearing a ketone or an ester function at the 4 position, these compounds being both appreciated for their biological⁴ and photophysical⁵ properties, and we decided to attempt their syntheses with recourse to less conventional activating systems than oil bath heating such as microwaves and ultrasounds. The study was then extended to reactions with other dipolarophiles, and the mechanism of these reactions was investigated using DFT calculations. Finally, some of the triazoles such synthesized were evaluated for their bactericidal and cytotoxic activities.

Results and discussion

Synthetic aspects

We first considered 13DC reactions between different aromatic azides on the one hand, and acetylacetone or methyl acetoacetate on the other hand. Since the first 1,2,3-triazole formations by reaction between aryl azides and methylene-activated compounds in the early 1900s,⁶ chemists have extended the scope of the reaction.^{5,7} The latter proceeds in good yields at room temperature but requires long reaction times, and higher temperatures lead to reduced conversions.^{7k} In addition, the efficiency of the reaction is lowered when electron-donating groups are present on the aryl azide.⁵

When 4-nitro-, 4-chloro-, 4-bromo-, and 3-nitrophenyl azides (**1a-d**) were treated with acetylacetone (**2a**, 2 equiv) in the presence of triethylamine (2 equiv), and using DMF as solvent, the 1,2,3-triazoles **3a-d** were isolated in high yields (Table 1, entries 1-4). As expected, a lower yield was noted when the nitro group was present at the 3 position instead of the 4 position. Similar results were recorded using methyl acetoacetate (**2b**)

Table 1 Cycloaddition reaction of aryl azides **1a-d** with acetylacetone (**2a**) and methyl acetoacetate (**2b**) performed at room temperature

entry	R (1)	R' (2)	product (3)	yield
1	4-NO ₂ (1a)	Me (2a)	3a	98%
2	4-Cl (1b)	Me (2a)	3b	85%
3	4-Br (1c)	Me (2a)	3c	90%

instead of acetylacetone to afford the derivatives **3e-h** satisfactorily (Table 1, entries 5-8).

A rising number of articles have advocated the use of microwave technology in organic synthesis. Harsh conditions such as high temperatures and long reaction times often required for cycloaddition reactions were generally improved using this technique.⁸ In order to reduce the reaction times, we thus decided to examine the effect of microwave irradiation on the reactions. Solvents being optional using this technology, the aryl azides were simply microwave-heated in the presence of 2 equiv of acetylacetone or methyl acetoacetate, and 2 equiv of triethylamine at 160 W. The precipitate formed after 5 min was then collected and washed with water. Whereas good results were obtained under these conditions from nitrophenyl azides **1a** and **1d** (Table 2, entries 1, 4, 5 and 8), moderate to low yields were observed using halogen-substituted phenyl azides **1b** and **1c** (Table 2, entries 2, 3, 6 and 7), and extended reaction times (15 min) and higher microwave powers did not allow to improve them.

The reactions under both types of conditions are regioselective. The nature of the regioisomer formed was established by NMR techniques: HMBC for the assignments of the methyl signals, and NOESY to confirm an interaction between the methyl group at the 5 position of the 1*H*-1,2,3-triazole ring and the phenyl ring. In

addition, the structures of the cycloadducts **3b**, **3c**, and **3f** were identified unequivocally by X-ray diffraction analysis.

α -Benzoylacetophenone (**4a**) and malonodinitrile (**4b**) similarly reacted with 4-nitrophenyl azide (**1a**) to afford the compounds **5a** and **5b**, respectively (Table 3). The former was identified by X-ray diffraction analysis. It was isolated in 40 and 85% yield, respectively at room temperature and under microwave irradiation, under the conditions employed before (entries 1 and 2). Using a catalytic amount of copper(I) chloride⁹ allowed to perform the reaction at room temperature in water in a satisfying 57% yield (entry 3). The same three sets of conditions were similarly employed to furnish the derivative **7** in 61, 59 and 70% yield, respectively (entries 4-6).

In the previous reactions, the 1,2,3-triazolines **6** were not observed due to elimination of water after the cycloaddition step according to the mechanism depicted in Scheme 1. More generally, the isolation of 4,5-dihydro-1*H*-1,2,3-triazoles, which are compounds of biological interest,¹⁰ is not obvious,¹¹ either due to subsequent elimination, or to cleavage with for example conversion to aziridines or diazo compounds.^{7h,12}

Scheme 1 Mechanism for the 1*H*-1,2,3-triazole formation.⁵

In order to study the effect of non-conventional activation ways on the degradation of 1,2,3-triazolines, we chose *N*-(2-hydroxyphenyl)acrylamide (**7a**), its 2-allyl derivative **7b** and *N*-vinylpyrrolidinone (**7c**), and examined their behavior toward 4-nitrophenyl azide (**1a**) (Table 4). At the reflux temperature of an apolar solvent such as toluene, the triazoline **8** was obtained from *N*-(2-hydroxyphenyl)acrylamide (**7a**) in a low 10% yield after 24 h reaction time (entry 1). Turning to acetone as solvent allowed the yield to reach 23% (entry 2). The reaction was also attempted without solvent, with recourse to microwave irradiation, but without success, the starting materials being recovered (entry 3). We thus decided to turn to ultrasound activation.¹³ Sonicating the acetone reaction mixture for 24 h resulted in an improved but still moderate 34% yield (entry 4), due to the formation of other derivatives. By replacing the sonication by an activation based on the catalytic use of a montmorillonite clay containing copper(II), Bentonite-Cu²⁺,¹⁴ and by using toluene as solvent, the side reactions were partly discarded, and the yield was improved to 68% (entry 5).

N-(2-Allyloxyphenyl)acrylamide (**7b**) regioselectively reacted at the conjugated double bond with 4-nitrophenyl azide (**1a**). The reaction performed at the reflux temperature of acetone worked in a moderate 20% yield (entry 6), as observed with *N*-(2-hydroxyphenyl)acrylamide (**7a**) (entry 2). A similar yield being obtained using a catalytic amount of Bentonite-Na⁺ in toluene at

Table 4 Cycloaddition reaction of 4-nitrophenyl azide (**1a**) with *N*-(2-hydroxyphenyl)acrylamide (**7a**), *N*-(2-allyloxyphenyl)acrylamide (**7b**) and *N*-vinylpyrrolidinone (**7c**) (1 equiv)

entry	dipolarophile	conditions	product	yield
1	7a	toluene, reflux, 24 h	8	10%

^a 1-(4-Nitrophenyl)-1*H*-1,2,3-triazole (**11**) was isolated in 58% yield.

room temperature under ultrasound activation (entry 7), we turned to the use of Bentonite-Cu²⁺: under the same reaction conditions, the triazoline **9** was isolated in 33% yield (entry 8).

Kadaba has shown that *N*-vinylamides can be used as dipolarophiles in reactions with aryl azides, and that the subsequent elimination of carboxamide largely depends on the reaction conditions.¹⁵ Compared with *N*-(2-hydroxyphenyl)acrylamide, *N*-vinylpyrrolidinone (**7c**) (dominant HOMO_{olefin}-LUMO_{azide} interactions)¹⁵ proved to react more efficiently with 4-nitrophenyl azide (**1a**). When acetone was used as solvent, the cycloadduct **10** was provided in 63% yield after 24 h reflux (entry 9). In contrast, recourse to microwave irradiation without solvent resulted in the elimination of 2-pyrrolidinone, giving 1-(4-nitrophenyl)-1*H*-1,2,3-triazole (**11**) in 58% yield (entry 10). These results are different from those reported by Kadaba, where elimination takes place at the reflux temperature of ethanol, and formation of triazolines occurs in the absence of solvent at room temperature.¹⁵

Calculations

1) DFT study of the mechanism of the domino reactions of β -dicarbonyl compounds **2** with 4-nitrophenyl azide (**1a**).

The thermal reactions between the β -dicarbonyl compounds **2** and 4-nitrophenyl azide **1a** are domino processes that comprise three consecutive reactions: i) a tautomeric equilibrium between the β -dicarbonyl compounds **2** and their enolic forms **2'**, ii) a 13DC reaction between the corresponding enols **2'** and 4-nitrophenyl azide (**1a**) to give the 4,5-dihydro-1,2,3-triazoles **6**, and iii) an acid-base catalyzed dehydration process to yield the final 1,2,3-triazoles **3** (see Scheme 2). In order to obtain mechanistic details, as well as to explain the complete regioselectivity experimentally observed in the formation of the 1,2,3-triazoles **3**, the two regioisomeric channels involved in the 13DC reactions were studied using DFT calculations at the B3LYP/6-31G* level.

The first reaction of this domino process is a tautomeric equilibrium between the keto and the enol forms of the β -dicarbonyl compounds **2**. The enols **2'** can adopt an *E* or *Z* configuration at the C4-C5 double bond. The *Z* isomers are 6.2 kcal/mol (**2'a-Z**) and 4.5 kcal/mol (**2'b-Z**) more stable than the

corresponding *E* isomers, due to the formation of an intramolecular hydrogen bond in the *Z* isomers (see Table 5). The formation of the **2'a-Z** and **2'b-Z** enols is exothermic by -5.2 and -0.2 kcal/mol, respectively. (As some species involved in these domino reactions have ionic character, the discussion is performed using the energies in acetonitrile).

Due to the asymmetry of the enols **2'** and 4-nitrophenyl azide (**1a**), the subsequent 13DC reactions can take place through two regioisomeric channels associated with the approach of the N1 nitrogen of 4-nitrophenyl azide (**1a**) to the C5 or the C4 carbon atoms of the enols **2'**, named 1 and 2, respectively. In order to analyze the role of the electron-withdrawing (EW) substitution in the aryl azides, the 13DC reaction of phenyl azide (**1e**) with the enol **2'a** was also studied. In addition, the two regioisomeric channels associated with these 13DC reactions were studied in order to explain the total regioselectivity experimentally observed (see Scheme 2).

The activation energies for the 13DC reactions of the enols **2'** with the aryl azides **1** through the more favorable regioisomeric channels 1 via **TS11** present very high values, between 22.2 to 24.7 kcal/mol (see Table 5). The 13DC reaction of the enol **2'a-Z** with phenyl azide (**1e**) has the largest activation energy, 24.7 kcal/mol (**TS11ea**) (the anachronism "e" is used to distinguish the species involved in the reactions of phenyl azide (**1e**)). A similar activation energy of 25.1 kcal/mol was obtained by single point energy calculations at the MP3/6-31G* level. The inclusion of an EW nitro group on the aryl substituent decreases slightly this unfavorable energy, 22.2 kcal/mol (**TS11a**). The similar

Scheme 2 Regioisomeric channels 1 and 2 associated with the thermal reactions of the β -dicarbonyl compounds **2** with the aryl azides **1**.

activation energy obtained for the 13DC reaction between the enol **2'b-Z** and 4-nitrophenyl azide (**1a**), 22.2 kcal/mol (**TS11b**), accounts for a similar reactivity for the enols **2'b-Z** and **2'a-Z**.

The activation energy for the 13DC reaction of the enol **2'a-Z** with phenyl azide (**1e**) via **TS11ea** is *ca.* 10 kcal/mol higher than that for the 13DC reaction of phenyl azide (**1e**) with methyl vinyl ether, as a model of electron-rich olefins,¹⁶ and higher than that obtained for the 13DC reaction of hydrazoic acid, N₃H, with ethylene, 19.5 kcal/mol,¹⁷ and with vinyl alcohol, 20.2 kcal/mol.¹⁸

The activation energies associated with the more unfavorable regioisomeric channels 2 via **TS12** are between 7.0 and 10.5 kcal/mol higher in energy than those associated with the channels 1 (see Table 5). These high energy differences, which are higher than that found by Nguyen for the regioisomeric TSs associated with the 13DC reactions between hydrazoic acid and vinyl alcohol, $\Delta\Delta E$ 5.1 kcal/mol,¹⁸ are in complete agreement with the total regioselectivity experimentally observed.

From the enols **2'** and the aryl azides **1**, the formation of the cycloadducts (CA) **61** and **62** is slightly exothermic (see Table 5).

The last reaction of these domino processes is the acid-base catalyzed dehydration of the CA **61**. These dehydration reactions proceed in three steps: i) a protonation at the keto or ester carbonyl oxygen atom of **61**, which correspond to the most basic centers, ii) an *E1* elimination of water at the hydroxy group of the protonated **61**, and iii) a hydrogen elimination at the vicinal C5 carbon atom to rebuild the C4–C5 double bond of the enol, thus yielding the final 1,2,3-triazoles **31** (see Scheme 3). We selected trimethylammonium cation as model of the acid catalyst.

The elimination process was studied for the thermal reactions of the β -dicarbonyl compounds **2a,b** with 4-nitrophenyl azide (**1a**). Because similar results were obtained for both β -dicarbonyl

Table 5 B3LYP/6-31G* relative energies (ΔE , in kcal/mol, relative i to **2**, ii to **1+2'**, and iii to **IN11** or **IN12**) in gas phase and in solution, of the stationary points involved in the thermal domino reactions of the β -dicarbonyl compounds **2** with the aryl azides **1**

compounds, only the results obtained for **1a** will be discussed for simplicity. Anyway, the conclusions obtained for this catalyzed dehydration process could be applied to the rest of the reactions.

Protonation of **61a** by trimethylammonium cation takes place at the carbonyl O8 oxygen atom, preserving the hydrogen bond between both oxygen atoms at the intermediate **IN11a** (see Scheme 3). Once protonated, **IN11a** loses a water molecule through an *E1* mechanism via **TS21a** with a very low activation energy of 5.4 kcal/mol. After passing **TS21a**, the subsequent proton elimination to yield the final adduct **31a** is downhill, being unfeasible to obtain the carbocation intermediate **IN21a** as a stationary point. This elimination reaction is very exothermic, -18.0 kcal/mol. This fact together with the favorable entropy associated with the loss of a water molecule, makes irreversible the domino reaction.

Similar energy results were obtained for the water elimination in the regioisomeric CA **62a** (see Table 5). Because the activation energies involved at the elimination reaction are lower than those involved in the 13DC reaction, it makes possible to discard a thermodynamic equilibration between the regioisomeric CAs **61a** and **62a**. Consequently, the formation of the final product **31a** is kinetically controlled in the 13DC reaction. Finally, similar results were obtained for the elimination reaction at the regioisomeric CAs **61b** and **62b** associated with the reaction of methyl acetoacetate (**2b**) (see Table 5).

The geometries of the TSs involved in the 13DC reaction between the enol **2'a-Z** and 4-nitrophenyl azide (**1a**) are given in Figure 1, while the geometrical and electronic parameters of the TSs involved in the 13DC reactions are given in Table 6. The lengths of the forming bonds at the TSs are 1.974 Å (N1-C5) and 2.251 Å (N3-C4) at **TS11a**, and 1.906 Å (N1-C4) and 2.150 Å (N3-C5) at **TS12a**. At these TSs the N-C bond formation at the unsubstituted N1 nitrogen atom of the aryl azide is slightly more advanced than that at the substituted N3 nitrogen atom.¹⁸ Similar bond formation is observed at the other 13DC reactions (see Table 6). The asynchronicity on the bond-formation in the cycloaddition reactions can be measured by the difference of the lengths of the σ forming bonds, Δl . The corresponding values are given in Table 6. These values are in the range of 0.1 to 0.3, indicating that the TSs correspond to concerted but asynchronous bond formation processes. For the 13DC reaction involving phenyl azide (**1e**), the **TS12ea** associated with the more unfavorable regioisomeric channel 2 is more asynchronous than the **TS11ea** associated with the channel 1, while for the reactions involving 4-nitrophenyl azide (**1a**), **TS11a** associated with the more favorable regioisomeric channels 1 are more asynchronous.

Scheme 3 Regioisomeric channels 1 and 2 associated with the elimination reactions of the CA **6**.

Table 6 Lengths of the C-N forming bonds (in angstroms), asynchronicity (Δl), charge transfer (CT, in e), and bond orders (BO) of the C-N forming bonds involved in the 13DC reactions between the enols **2'** and the aryl azides **1**

	N1-C5(4)	N3-C4(5)	Δl	CT	BO N1-C5(4)	BO N3-C4(5)

Fig. 1 Transition states involved in the regioisomeric channels 1 and 2 associated with the 13DC reaction and water elimination steps of the thermal domino reaction between the β -dicarbonyl compound **2a** with 4-nitrophenyl azide (**1a**).

The extension on bond-formation at the TSs is provided by the bond order (BO).¹⁹ The BO values at the TSs associated with the 13DC reactions are given in Table 6. At the TSs associated with the more favorable regioisomeric channels 1, the BO values of the N1-C5 forming bonds are in the range of 0.45 – 0.48, while those for the N3-C4 forming bonds are in the range of 0.25 – 0.29. The bond formation at the unsubstituted N1 is more advanced than at the substituted N3 atom. At the most favorable regioisomeric channels 1, the TSs involving 4-nitrophenyl azide (**1a**) are more advanced and more asynchronous. At the TSs associated with the more unfavorable regioisomeric channels 2, the BO values of the N1-C4 forming bonds are in the range of 0.45 – 0.49, while those for the N3-C5 forming bonds are in the range of 0.33 – 0.34. These TSs are slightly more advanced and more synchronous than the regioisomeric TSs 1.

The natural population analysis (NPA) allows us to evaluate the charge transfer (CT) at the TSs. The natural charges at the TSs were shared between the aryl azides **1** and the enols **2'**. The CT, which takes place from the enols **2'** to the azides **1**, is given in Table 6. The CT at the TSs associated with the more favorable regioisomeric channels 1, between 0.17e and 0.26e, is larger than that at the TSs associated with the regioisomeric channels 2, between 0.08e and 0.15e. The more polar TSs are those associated with the 13DC reactions between the electron-rich enols **2'a-Z** and **2'b-Z** with electron-deficient (ED) 4-nitrophenyl

azide (**1a**).

Finally, the geometries of the TSs involved in the elimination reaction of the CAs **61a** and **62a** are given in Figure 1. The lengths of the breaking and forming bonds at the TSs involved in the water elimination step are given in Table 7. At **TS21a**, the length of the C4–O6 breaking bond is 1.627 Å, while the lengths of the O8–H7 breaking and H7–O6 forming bonds are 1.305 and 1.129 Å, respectively. The length of the N10–H9 hydrogen bond is 1.997 Å. At **TS22a**, the length of the C4–O6 breaking bond is 1.740 Å, while the lengths of the O8–H7 breaking and H7–O6 forming bonds are 1.599 and 1.016 Å, respectively. The length of the N10–H9 hydrogen bond is 2.196 Å. At **TS22a** the water elimination process is more advanced than at **TS21a**.

Similar geometrical parameters were obtained for the water elimination step of the domino reaction between the enol **2'b** and the aryl azide **1a** (see Table 7).

Table 7 Lengths of the breaking and forming bonds (in angstroms) in the TSs involved in the water elimination step

	C4-O6	O8-H7	H7-O6	H9-N10
TS21a	1.627	1.305	1.129	1.997
TS22a	1.740	1.599	1.016	2.196
TS21b	1.619	1.280	1.145	1.941
TS22b	1.941	1.578	1.022	2.078

2) Analysis based on the global and local reactivity indexes at the ground state of the reagents.

Recent studies carried out on cycloaddition reactions²⁰ have shown that the analysis of the reactivity indices defined within the conceptual DFT²¹ is a powerful tool to study the reactivity in polar cycloadditions. In Table 8, the static global properties (electronic chemical potential, μ , chemical hardness, η , global electrophilicity, ω , and global nucleophilicity, N) of the enols **2'** and the aryl azides **1** are presented. The global properties of 4-chlorophenyl azide (**1b**), 4-bromophenyl azide (**1c**) and hydrazoic acid, N_3H are also included for comparative purposes.

The electronic chemical potential of 4-nitrophenyl azide (**1a**), $\mu = -0.1771$ au, is lower than those for the enolates, $\mu = -0.1396$ (**2'a**) and -0.1306 (**2'b**) au, indicating thereby that along a polar 13DC reaction the net CT will take place from these enolates

Table 8 Electronic chemical potential, (μ , in au), chemical hardness, (η , in au), global electrophilicity, (ω , in eV), and global nucleophilicity, (N , in eV), of the enols **2'** and the aryl azides **1**

	μ (au)	η (au)	ω (eV)	N (eV)
1a	-0.1771	0.1605	2.66	2.12
1b	-0.1393	0.1856	1.42	2.81
1c	-0.1385	0.1839	1.42	2.85
N_3H	-0.1557	0.2404	1.37	1.62
2'a-Z	-0.1396	0.1968	1.35	2.65
1e	-0.1331	0.1897	1.27	2.92
2'b-Z	-0.1306	0.2082	1.11	2.74

towards ED 4-nitrophenyl azide (**1a**), in clear agreement with the CT analysis performed at the TSs.

The electrophilicity and nucleophilicity indices of hydrazoic acid, N₃H, have low values, $\omega = 1.37$ and $N = 1.62$ eV. This means that the simplest azide does not participate in polar processes. Phenyl azide (**1e**) shows a slight electrophilic deactivation, $\omega = 1.27$ eV, and a slight nucleophilic activation, $N = 2.92$ eV (see Table 8). The inclusion of an halogen atom in the 4 position of benzene produces a slight electrophilic activation, $\omega = 1.42$ eV for **1b** and **1c**. A more clear electrophilic activation is found at ED 4-nitrophenyl azide (**1a**), which has an $\omega = 2.66$ eV. On the other hand, the electrophilicity and nucleophilicity indices of the enols are $\omega = 1.35$ and $N = 2.65$ eV for **2'a-Z**, and $\omega = 1.11$ and $N = 2.74$ eV for **2'b-Z**. Therefore, they will act as moderate nucleophiles.

Analysis of the global reactivity indices indicates that these reactions will take place through cycloadditions with low polar character. Only the 13DC reactions involving the EW 4-nitrophenyl group will present a large polar character.

Finally, the analysis of the local electrophilicity ω_k at the electrophilic azides and the local nucleophilicity N_k at the nucleophilic enols allows for a rationalization of the regioselectivity of cycloadditions.²² The values of the corresponding local indices are given in Table 9. The enols **2'a,b** present the largest nucleophilic activation at the C5 carbon atom, which corresponds with the β carbon atom of the enols. On the other hand, 4-nitrophenyl azide (**1a**) presents the largest electrophilic activation at the terminal N1 nitrogen atom.²³ Note that the N2 Nitrogen also presents an electrophilic activation. Consequently, the more favorable regioisomeric channel will correspond with the earlier formation of the N1-C5 σ bonds than the N3-C4 one, in clear agreement with the energy results and with the asynchronicity found at the TSs.

Table 9 Local electrophilicity (ω_k , in eV) and nucleophilicity (N_k , in eV) indices of the enols **2'** and the aryl azides **1**

	ω_{N1}	ω_{N2}	ω_{N3}	N_{C4}	N_{C5}
1e	0.62	0.44	0.13	0.32	1.32
1a	1.30	0.92	0.27	0.37	1.39

3) Conclusions.

The thermal reactions between acetylacetone (**2a**) and methyl acetoacetate (**2b**) with ED 4-nitrophenyl azide (**1a**) have been theoretically studied using DFT methods at the B3LYP/6-31G*

level. They are domino processes that comprise three consecutive reactions: i) a tautomeric equilibrium of the β -dicarbonyl compounds **2** with their enol forms **2'**, ii) a 13DC reaction of the enol forms **2'** with 4-nitrophenyl azide (**1a**) to yield the 4,5-dihydro-1,2,3-triazoles **6**, and iii) an acid-base catalyzed dehydration process in **6** to yield the final 1,2,3-triazoles **3**. For 13DC reactions, the two regioisomeric channels have been studied.

The 13DC reactions present high activation energies, which are only slightly reduced by the use of ED 4-nitrophenyl azide (**1a**). The higher activation energies associated with the regioisomeric channels 2 prevent the formation of the corresponding cycloadducts, these 13DC reactions being completely regioselective.

The lower activation energies of the water elimination step, respect to the 13DC reaction, together with the irreversible character of this dehydration process make possible to displace the reaction toward the formation of the final 1,2,3-triazoles **3**.

Pharmacology

Applying the agar plate diffusion technique,²⁴ the newly synthesized compounds **3a-h** and **5a** were screened in vitro for their bactericidal activity against Gram positive bacteria (*Staphylococcus aureus*) and Gram negative bacteria (*Escherichia Coli* and *Pseudomonas aeruginosa*), and for their fungicidal activity towards *Fusarium oxysporium*, *Aspergillus niger* and *Candida albicans* (Table 10). The compounds **3a-c** and **3e-g** showed moderate bactericidal activities against *Staphylococcus Aureus* and *Escherichia Coli* compared to that of ciprofloxacin as a reference drug, and the compounds **3d, 3h** and **5a** showed significant activities against *Staphylococcus Aureus*. All the compounds tested showed moderate fungicidal activities towards *Fusarium oxysporium* and *Aspergillus niger* compared to that of nystin as a reference, except the compounds **3b-d** that showed significant activities against *Fusarium oxysporium*. All the compounds tested showed no activity against *Candida albicans*.

The same compounds were also tested against a human liver carcinoma cell line (HEPG2) (Table 11). Moderate cytotoxic activities were observed, except for the compounds **3d** and **5a** (entries 4 and 9), which were found to have significant activities, compared to a reference drug (doxorubicin).

Table 10 Bactericidal and fungicidal activity^a of the compounds **3a-h**, **5a**, and ciprofloxacin and nystin

^a The diameters of zones of inhibition are given in mm. Stock solution: 5 μ g in 1 mL of DMF. 0.1 mL of stock solution in each hole of each paper disk. +: < 15 mm; ++: 15-24 mm; +++: 25-34 mm; ++++: 35-44 mm, etc.

Table 11 In vitro cytotoxic activity (IC_{50})^a of the compounds **3a-h**, **5a**, and doxorubicin against a liver carcinoma cell line (HEPG2)

entry	compound	HEPG2 ($\mu\text{g.mL}^{-1}$)
1	3a	3.34
2	3b	2.88
3	3c	2.92
4	3d	0.53
5	3e	2.46
6	3f	3.11
7	3g	2.24
8	3h	3.74
9	5a	0.81
10	doxorubicin	0.60

^a IC_{50} is defined as the concentration which results in a 50% decrease in cell number as compared with that of the control structures in the absence of an inhibitor.

Conclusions

Reactions performed between aryl azides on the one hand, and activated alkenes coming from β -dicarbonyl compounds or malonodinitrile on the other hand showed that microwave activation allowed the reaction times to be considerably reduced in the case of nitrophenyl azides. With the help of DFT methods at the B3LYP/6-31G* level, the mechanism of the reactions involving β -dicarbonyl compounds was studied, and their regioselectivity explained. They are domino processes that comprise a tautomeric equilibrium of the β -dicarbonyl compound with its enol form, a 13DC with the aryl azide, and a dehydration process. The lower activation energy of the last step compared with the previous one helps to explain why 1,2,3-triazolines were not obtained, but the corresponding 1,2,3-triazoles. The effect of non-conventional activation ways on the degradation of other 1,2,3-triazolines was next studied experimentally. Finally, some among the 1,2,3-triazoles evaluated exhibited interesting bactericidal and cytotoxic activities.

Experimental

Syntheses: general methods

Liquid chromatography separations were achieved on silica gel Merck-Geduran Si 60 (40-63 μm). Petrol refers to petroleum ether (bp 40-60 $^{\circ}\text{C}$). Melting points were measured on a Kofler apparatus. Infrared spectra were recorded on a JASCO FT/IR-4200 apparatus, and main wavenumbers are given in cm^{-1} . Nuclear Magnetic Resonance spectra were acquired using a Bruker AC-300 spectrometer (300 MHz and 75 MHz for ^1H and ^{13}C respectively). ^1H chemical shifts (δ) are given in ppm relative to the solvent residual peak, and ^{13}C chemical shifts relative to the central peak of the solvent signal. Assignments of protons and carbons could be made on the basis of bidimensional techniques (NOESY, HMBC and HMQC experiments) using a Avance 500 spectrometer (500 MHz and 125 MHz for ^1H and ^{13}C respectively). High resolution mass spectra measurements were recorded at the Centre Régional de Mesures Physiques de l'Ouest (CRMPO) in Rennes. Microwave reactions were performed in a Whirlpool M571 domestic oven using open glass containers.

Bentonite- Cu^{2+14} was obtained as follows. Deposit bentonite (60 g) was dried (80 $^{\circ}\text{C}$, 18 h), crushed and sieved (200 μm) before treatment in order to remove carbonates (calcite and dolomite) at pH 2-3 (addition of 0.1 N HCl to a suspension in water) for 12 h, and adjustment at pH 7. The clay was then

scattered in aqueous 1 M NaCl; three stirring of the suspension for 12 h, centrifugation (4500 t.min^{-1}) and washing sequences were then performed. After two drying (80 $^{\circ}\text{C}$ and 105 $^{\circ}\text{C}$)-crushing steps, resulting bentonite- Na^+ was suspended in water (50 g.l^{-1}); the suspension was stirred and treated over 12 h by an aqueous 1 N CuCl_2 solution (0.5 L). This was repeated three times after decantation and removal of the supernatant liquid. Bentonite- Cu^{2+} was washed using water, centrifuged (5000 t.min^{-1}), and dried at 60 $^{\circ}\text{C}$. After crushing and sieving (60 μm), it was dried again at 105 $^{\circ}\text{C}$ for 12 h.

Aryl azides were prepared according to the method of Nolting and Michel.²⁵ *N*-(2-Hydroxyphenyl)acrylamide (**7a**) was prepared as described previously.²⁶ *N*-(2-Allyloxyphenyl)acrylamide (**7b**) was prepared using a described procedure,²⁷ and recrystallized from 1:1 EtOH/ H_2O : yield: 79%; yellow powder, mp 37 $^{\circ}\text{C}$; IR (KBr): 1542, 1668, 3018, 3223; ^1H NMR (300 MHz, CDCl_3) 4.78 (d, 2H, $J = 5.7$ Hz), 5.47 (dd, 1H, $J = 1.3$ and 17 Hz), 5.56 (dd, 1H, $J = 1.3$ and 10 Hz), 5.91 (d, 1H, $J = 10$ Hz), 6.27 (ddd, 1H, $J = 5.7$, 10 and 17 Hz), 6.44 (dd, 2H, $J = 10$ and 17 Hz), 6.55 (d, 1H, $J = 17$ Hz), 7.00-7.25 (m, 4H), 8.03 (s, 1H); ^{13}C NMR (75 MHz, CDCl_3) 69.6 (OCH_2), 113.7 (CH_2), 115.5 (CH_2), 120.0 (CH), 121.5 (CH), 122.4 (CH), 127.7 (CH), 130.1 (CH), 132.0 (CH), 135.6 (C), 153.5 (C), 168.0 (C=O).

General procedure 1. To the required methylene-activated compound (10 mmol) and Et_3N (10 mmol) in DMF (2 mL) was added the required azide (5 mmol), and the mixture was stirred at room temperature for 24 h. The precipitate was filtrated, washed with H_2O , dried, and recrystallized from $i\text{PrOH}$.

General procedure 2. To the required methylene-activated compound (10 mmol) and Et_3N (10 mmol) was added the required azide (5 mmol), and the mixture was microwave-heated at 160 W for 5 min. The precipitate was washed with H_2O and dried.

General procedure 3. To the required methylene-activated compound (10 mmol) and Et_3N (10 mmol) in DMF (2 mL) was added the required azide (5 mmol) and CuCl (1 mmol), and the mixture was stirred at room temperature for 17 h. The precipitate was filtrated, washed with H_2O , dried, and recrystallized from $i\text{PrOH}$.

5-Methyl-1-(4-nitrophenyl)-1H-1,2,3-triazole-4-ethanone (3a). Yield: 98% (general procedure 1), 72% (general procedure 2). Yellow needles, mp 146 $^{\circ}\text{C}$ (lit.²⁸ 132-133 $^{\circ}\text{C}$). IR (KBr): 1520, 1680, 3102. ^1H NMR (300 MHz, CDCl_3): 2.71 (s, 3H), 2.78 (s, 3H), 7.76 (d, 2H, $J = 8.8$ Hz), 8.50 (d, 2H, $J = 8.8$ Hz). ^{13}C NMR (75 MHz, CDCl_3): 10.8 (CH_3), 28.4 (CH_3), 125.7 (2 CH), 126.2 (2 CH), 137.8 (C), 140.6 (C), 144.5 (C), 148.6 (C), 194.5 (C=O). HRMS (ESI): calcd for $\text{C}_{11}\text{H}_{10}\text{N}_4\text{NaO}_3$ [(M+Na) $^{+}$] 269.0651, found 269.0653.

5-Methyl-1-(4-chlorophenyl)-1H-1,2,3-triazole-4-ethanone (3b). Yield: 85% (general procedure 1), 37% (general procedure 2). Pale yellow powder, mp 112 $^{\circ}\text{C}$ (lit.²⁹ 108-110 $^{\circ}\text{C}$). IR (KBr): 836, 1550, 1687, 3104. ^1H NMR (300 MHz, CDCl_3): 2.60 (s, 3H), 2.76 (s, 3H), 7.41 (d, 2H, $J = 8.7$ Hz), 7.57 (d, 2H, $J = 8.7$ Hz). ^{13}C NMR (75 MHz, CDCl_3): 10.1 (CH_3), 27.9 (CH_3), 126.5 (2 CH), 130.0 (2 CH), 133.8 (C), 136.3 (C), 137.4 (C), 143.8 (C),

194.3 (C=O). HRMS (ESI): calcd for $C_{11}H_{10}^{35}ClN_3NaO$ [(M+Na)⁺] 258.0410, found 258.0413.

5-Methyl-1-(4-bromophenyl)-1H-1,2,3-triazole-4-ethanone

(3c). Yield: 90% (general procedure 1), 46% (general procedure 2). White powder, mp 116 °C (lit.²⁹ 108-110 °C. IR (KBr): 645, 1549, 1688, 3092. ¹H NMR (300 MHz, CDCl₃): 2.63 (s, 3H), 2.78 (s, 3H), 7.38 (d, 2H, J = 8.6 Hz), 7.75 (d, 2H, J = 8.6 Hz). ¹³C NMR (75 MHz, CDCl₃): 10.6 (CH₃), 28.3 (CH₃), 124.7 (C), 127.1 (2 CH), 133.4 (2 CH), 134.7 (C), 137.8 (C), 144.2 (C), 194.7 (C=O). HRMS (ESI): calcd for $C_{11}H_{10}^{79}BrN_3NaO$ [(M+Na)⁺] 301.9905, found 301.9905.

5-Methyl-1-(3-nitrophenyl)-1H-1,2,3-triazole-4-ethanone (3d).

Yield: 65% (general procedure 1), 70% (general procedure 2). Yellow powder, mp 118 °C. IR (KBr): 1561, 1721, 3096. ¹H NMR (300 MHz, CDCl₃): 2.71 (s, 3H), 2.80 (s, 3H), 7.89 (m, 2H), 7.75 (m, 2H). ¹³C NMR (75 MHz, CDCl₃): 10.6 (CH₃), 28.4 (CH₃), 102.6 (C), 120.7 (CH), 125.1 (CH), 131.3 (CH), 131.3 (CH), 136.7 (C), 137.9 (C), 149.2 (C), 194.6 (C=O). HRMS (ESI): calcd for $C_{11}H_{10}N_4NaO_3$ [(M+Na)⁺] 269.0651, found 269.0656.

Methyl 5-methyl-1-(4-nitrophenyl)-1H-1,2,3-triazole-4-carboxylate (3e).

Yield: 80% (general procedure 1), 93% (general procedure 2). Yellow powder, mp 170 °C (lit.³⁰ 154 °C). IR (KBr): 1116, 1530, 1738, 3119. ¹H NMR (300 MHz, CDCl₃): 2.73 (s, 3H), 4.04 (s, 3H), 7.78 (d, 2H, J = 9.1 Hz), 8.51 (d, 2H, J = 9.1 Hz). ¹³C NMR (75 MHz, CDCl₃): 10.2 (CH₃), 52.3 (CH₃), 125.2 (2 CH), 125.9 (2 CH), 137.2 (C), 139.0 (C), 140.2 (C), 148.3 (C), 161.8 (C=O). HRMS (ESI): calcd for $C_{11}H_{10}N_4NaO_4$ [(M+Na)⁺] 285.0600, found 285.0604.

Methyl 5-methyl-1-(4-chlorophenyl)-1H-1,2,3-triazole-4-carboxylate (3f).

Yield: 92% (general procedure 1), 16% (general procedure 2). White powder, mp 188 °C. IR (KBr): 817, 1095, 1561, 1725, 3104. ¹H NMR (300 MHz, CDCl₃): 2.61 (s, 3H), 3.99 (s, 3H), 7.42 (d, 2H, J = 8.8 Hz), 7.57 (d, 2H, J = 8.8 Hz). ¹³C NMR (75 MHz, CDCl₃): 10.0 (CH₃), 52.1 (CH₃), 126.6 (2 CH), 130.0 (2 CH), 133.9 (C), 136.3 (C), 136.7 (C), 139.0 (C), 162.0 (C=O). HRMS (ESI): calcd for $C_{11}H_{10}^{35}ClN_3NaO_2$ [(M+Na)⁺] 274.0359, found 274.0363.

Methyl 5-methyl-1-(4-bromophenyl)-1H-1,2,3-triazole-4-carboxylate (3g).

Yield: 78% (general procedure 1), 20% (general procedure 2). White powder, mp 200 °C. IR (KBr): 665, 1115, 1561, 1725, 3097. ¹H NMR (300 MHz, CDCl₃): 2.60 (s, 3H), 3.99 (s, 3H), 7.36 (d, 2H, J = 8.4 Hz), 7.72 (d, 2H, J = 8.4 Hz). ¹³C NMR (75 MHz, CDCl₃): 10.0 (CH₃), 52.1 (CH₃), 124.3 (C), 126.8 (2 CH), 133.0 (2 CH), 134.4 (C), 136.7 (C), 138.9 (C), 162.0 (C=O). HRMS (ESI): calcd for $C_{11}H_{10}^{79}BrN_3NaO_2$ [(M+Na)⁺] 317.9854, found 317.9856.

Methyl 5-methyl-1-(3-nitrophenyl)-1H-1,2,3-triazole-4-carboxylate (3h).

Yield: 71% (general procedure 1), 75% (general procedure 2). Yellow powder, mp 140 °C. IR (KBr): 1092, 1561, 1736, 3104. ¹H NMR (300 MHz, CDCl₃): 2.70 (s, 3H), 4.01 (s, 3H), 7.90 (m, 2H), 8.44 (m, 2H). ¹³C NMR (75 MHz, CDCl₃): 10.5 (CH₃), 52.6 (CH₃), 120.7 (CH), 125.2 (CH), 131.4 (CH), 131.4 (CH), 136.7 (C), 137.4 (C), 139.5 (C), 149.1

(C), 162.2 (C=O). HRMS (ESI): calcd for $C_{11}H_{10}N_4NaO_4$ [(M+Na)⁺] 285.0600, found 285.0600.

1-(4-Nitrophenyl)-5-phenyl-1H-1,2,3-triazole-4-

(phenylketone) (5a).⁷¹ Yield: 40% (general procedure 1), 85% (general procedure 2), 57% (general procedure 3). Beige powder, mp 172 °C. ¹H NMR (300 MHz, (CD₃)₂CO): 7.45 (m, 5H), 7.55 (m, 2H), 7.67 (tt, 1H, J = 7.4 and 1.4 Hz), 7.76 (d, 2H, J = 9.3 Hz), 8.23 (dd, 1H, J = 8.4 and 1.2 Hz), 8.37 (d, 2H, J = 9.3 Hz). ¹³C NMR (75 MHz, (CD₃)₂CO): 125.1 (2 CH), 126.4 (C), 127.1 (2 CH), 128.7 (2 CH), 128.9 (2 CH), 130.4 (CH), 130.8 (2 CH), 130.8 (2 CH), 133.5 (CH), 137.8 (C), 141.3 (C), 141.9 (C), 144.2 (C), 148.5 (C), 186.4 (C=O).

5-Amino-1-(4-nitrophenyl)-1H-1,2,3-triazole-4-carbonitrile

(5b).³¹ Yield: 61% (general procedure 1), 59% (general procedure 2), 70% after 2 h reaction time and 87% after 24 h reaction time (general procedure 3). Beige powder, mp 204 °C. ¹H NMR (300 MHz, (CD₃)₂CO): 6.82 (br s, 2H), 8.01 (d, 2H, J = 8.7 Hz), 8.50 (d, 2H, J = 8.7 Hz). ¹³C NMR (75 MHz, (CD₃)₂CO): 101.9 (C), 105.0 (C), 114.1 (C), 127.1 (2 CH), 127.4 (2 CH), 141.4 (C), 149.9 (C). HRMS (EI): calcd for $C_9H_8N_6O_2$ [M⁺] 232.0709, found 232.0709.

N-(2-Hydroxyphenyl) 1-(4-nitrophenyl)-4,5-dihydro-1H-1,2,3-triazole-4-carboxamide (8).

To *N*-(2-hydroxyphenyl)acrylamide (**7a**, 3 mmol) in toluene (25 mL) was added 4-nitrophenyl azide (**1a**, 3 mmol) and bentonite-Cu²⁺ (0.1 g), and the mixture was heated under reflux for 24 h. The precipitate was filtrated, and extracted with acetone. After removal of the solvent, the product was recrystallized from EtOH. Yield: 68%. Yellow powder, mp 196 °C. IR (KBr): 1095, 1596, 1671, 3079, 3198, 3388. ¹H NMR (200 MHz, (CD₃)₂SO): 3.40 (d, 2H, J = 11 Hz), 5.83 (t, 1H, J = 11 Hz), 6.88 (m, 3H), 7.49 (d, 2H, J = 8.6 Hz), 7.90 (s, 1H), 8.26 (d, 2H, J = 8.6 Hz), 9.81 (s, 1H), 10.0 (s, 1H). ¹³C NMR (50 MHz, (CD₃)₂SO): 43.8 (CH₂), 81.4 (CH), 114.5, 115.4, 115.6, 119.3, 122.2, 125.4, 125.9, 126.1, 135.9, 141.9, 145.5, 165.4 (C=O).

N-(2-Allyloxyphenyl) 1-(4-nitrophenyl)-4,5-dihydro-1H-1,2,3-triazole-4-carboxamide (9).

To *N*-(2-allyloxyphenyl)acrylamide (**7b**, 2 mmol) in toluene (15 mL) was added 4-nitrophenyl azide (**1a**, 2 mmol) and bentonite-Cu²⁺ (0.1 g), and the mixture was sonicated for 7 h. The precipitate was filtrated, and extracted with acetone. After removal of the solvent, the product was recrystallized from EtOH. Yield: 33%. Yellow powder, mp 220 °C. IR (KBr): 1115, 1597, 1679, 3080, 3368. ¹H NMR (200 MHz, CDCl₃): 3.35 (2 d, 2H, J = 18 and 19 Hz), 3.55 (d, 1H, J = 18 Hz), 3.91 (d, 1H, J = 19 Hz), 4.65 (d, 2H, J = 5.6 Hz), 5.34 (dd, 1H, J = 1.3 and 10 Hz), 5.48 (dd, 1H, J = 1.3 and 17 Hz), 6.09 (ddd, 1H, J = 5.6, 10 and 17 Hz), 6.50 (s, 1H), 6.63 (d, 2H, J = 8.8 Hz), 6.90-7.20 (m, 4H), 8.10 (dd, 2H, J = 8.8 Hz). ¹³C NMR (50 MHz, CDCl₃): 46.9 (CH₂), 69.2 (CH₂), 69.3 (CH), 117.6 (CH₂), 119.2 (2 CH), 121.4 (CH), 121.5 (CH), 124.1 (2 CH), 124.1 (CH), 124.9 (CH), 129.2 (CH), 147.1 (C), 147.5 (C), 149.0 (C), 163.2 (C), 181.8 (C=O). HRMS (EI): calcd for $C_{18}H_{17}N_5O_4$ [M⁺] 367.1281, found 367.1281.

1-(1-(4-Nitrophenyl)-4,5-dihydro-1H-1,2,3-triazolyl)-2-

pyrrolidinone (10). To *N*-vinylpyrrolidinone (**7c**, 5 mmol) in acetone (30 mL) was added 4-nitrophenyl azide (**1a**, 5 mmol),

and the mixture was heated under reflux for 24 h. The precipitate was filtrated, and the product was recrystallized from EtOH. Yield: 63%. Yellow powder, mp 184 °C. IR (KBr): 1047, 1599, 1685, 3113. ¹H NMR (200 MHz, CDCl₃): 1.90 (m, 2H), 2.35 (m, 2H), 2.62 (m, 1H), 2.96 (m, 1H), 4.44 (t, 2H, J = 2.1 Hz), 6.38 (dd, 1H, J = 4.0 and 8.3 Hz), 7.45 (d, 2H, J = 9.2 Hz), 8.22 (d, 2H, J = 9.2 Hz). ¹³C NMR (50 MHz, CDCl₃): 17.8 (CH₂), 30.7 (CH₂), 41.7 (CH₂), 58.9 (CH₂), 69.7 (CH), 108.5, 114.9, 126.4, 143.4, 143.8, 155.4, 175.9 (C=O). **1-(4-Nitrophenyl)-1H-1,2,3-triazole (11)** was obtained instead in 58% yield using the following procedure: To *N*-vinylpyrrolidinone (5 mmol) was added 4-nitrophenyl azide (**1a**, 5 mmol), and the mixture was microwave-heated at 350 W for 10 min. The product collected with EtOH was washed and dried. Mp 204 °C (lit.³² 205-207 °C).

Crystallography

Single crystals suitable for X-ray diffraction were grown after slow evaporation (several days at room temperature) of solutions of **3b**, **3c**, **3f** and **5a** in AcOEt. The samples were studied with graphite monochromatized MoK_α radiation (λ = 0.71073 Å). X-ray diffraction data were collected at T = 100(2) K for **3c** and **5a**, and at T = 150(2) K for **3b** and **3f**, using APEXII Bruker-AXS diffractometer. The structure was solved by direct methods using the SIR97 program,³³ and then refined with full-matrix least-square methods based on F² (SHELX-97)³⁴ with the aid of the WINGX program.³⁵ All non-hydrogen atoms were refined with anisotropic atomic displacement parameters. H atoms were finally included in their calculated positions. Molecular diagrams were generated by ORTEP-3 (version 1.08).³⁶

Crystal data for **3b**: C₁₁H₁₀ClN₃O, M = 235.67, triclinic, *P*-1, *a* = 5.5353(2), *b* = 6.5391(3), *c* = 15.0596(7) Å, α = 85.657(1), β = 81.972(1), γ = 89.189(2)°, *V* = 538.20(4) Å³, *Z* = 2, *d* = 1.45 g.cm⁻³, μ = 0.335 mm⁻¹. A final refinement on F² with 2440 unique intensities and 147 parameters converged at ωR(F²) = 0.0817 (R(F) = 0.0302) for 2317 observed reflections with *I* > 2σ(*I*).

Crystal data for **3c**: C₁₁H₁₀BrN₃O, M = 280.13, triclinic, *P*-1, *a* = 5.6105(2), *b* = 6.4884(3), *c* = 15.2886(7) Å, α = 86.338(2), β = 81.785(2), γ = 89.249(2)°, *V* = 549.71(4) Å³, *Z* = 2, *d* = 1.69 g.cm⁻³, μ = 3.72 mm⁻¹. A final refinement on F² with 2494 unique intensities and 147 parameters converged at ωR(F²) = 0.0446 (R(F) = 0.0179) for 2396 observed reflections with *I* > 2σ(*I*).

Crystal data for **3f**: 2(C₁₁H₁₀ClN₃O₂); M = 503.34, orthorhombic, *Pbc*2₁, *a* = 3.8164(1), *b* = 12.7220(3), *c* = 46.6476(13) Å, *V* = 2264.85(10) Å³, *Z* = 4, *d* = 1.48 g.cm⁻³, μ = 0.330 mm⁻¹. A final refinement on F² with 4171 unique intensities and 311 parameters converged at ωR(F²) = 0.0874 (R(F) = 0.0403) for 3781 observed reflections with *I* > 2σ(*I*).

Crystal data for **5a**: C₂₁H₁₄N₄O₃, M = 370.36, monoclinic, *C*2/c, *a* = 28.5149(9), *b* = 8.7547(3), *c* = 14.6996(5) Å, β = 110.800(2)°, *V* = 3430.4(2) Å³, *Z* = 8, *d* = 1.43 g.cm⁻³, μ = 0.099 mm⁻¹. A final refinement on F² with 3847 unique intensities and 253 parameters converged at ωR(F²) = 0.0905 (R(F) = 0.037) for 3284 observed reflections with *I* > 2σ(*I*).

Computational methods

All calculations were carried out with the Gaussian 03 suite of

programs³⁷. DFT calculations were carried out using the B3LYP³⁸ exchange-correlation functionals, together with the standard 6-31G(d) basis set.³⁹ The optimizations were carried out using the Berny analytical gradient optimization method.⁴⁰ The stationary points were characterized by frequency calculations in order to verify that TSs have one and only one imaginary frequency. The intrinsic reaction coordinate (IRC)⁴¹ paths were traced in order to check the energy profiles connecting each TS to the two associated minima of the proposed mechanism using the second order González-Schlegel integration method.⁴² The stationary points were also optimized using the 6-311+G** basis set. The energy and geometry results are given in Supplementary Material. No significant changes in relative energies and geometries were found. The electronic structures of stationary points were analyzed by the natural bond orbital (NBO) method.⁴³

Solvent effects have been considered at the same level of theory by single point energy calculations of the gas-phase structures using a self-consistent reaction field (SCRF)⁴⁴ based on the polarizable continuum model (PCM) of the Tomasi's group.⁴⁵ As polar solvent we selected acetonitrile (ε = 35.69), which has a dielectric constant similar to the experimental solvent, dimethylformamide (ε = 36.7).

The global electrophilicity index,⁴⁶ ω, has been given by the simple expression ω = (μ²/2η) (eV), in terms of the electronic chemical potential μ and the chemical hardness η. Both quantities may be calculated in terms of one of the electron HOMO and LUMO energies, ε_H and ε_L, as μ ≈ (ε_H + ε_L)/2 and η ≈ (ε_L - ε_H), respectively.⁴⁷ Recently, we have introduced an empirical (relative) nucleophilicity index, N, based on the HOMO energies obtained within the Kohn-Sham scheme,⁴⁸ defined as N = E_{HOMO(Nu)} - E_{HOMO(TCE)} (eV).⁴⁹ This nucleophilicity scale takes tetracyanoethylene (TCE) as a reference. Local electrophilicity⁵⁰ and nucleophilicity⁵¹ indices, ω_k and N_k, were evaluated using the following expressions: ω_k = ωf_k⁺ and N_k = Nf_k⁻ where f_k⁺ and f_k⁻ are the Fukui functions for a nucleophilic and electrophilic attacks, respectively.⁵²

Pharmacology

Applying the agar plate diffusion technique,²⁴ the compounds were screened in vitro for their bactericidal activity against Gram positive bacteria (*Staphylococcus aureus*) and Gram negative bacteria (*Escherichia Coli* and *Pseudomonas aeruginosa*), and for their fungicidal activity against *Fusarium oxysporum*, *Aspergillus niger* and *Candida albicans*. In this method, a standard 5 mm diameter sterilized filter paper disc impregnated with the compound (0.3 mg/0.1 ml of DMF) was placed on an agar plate seeded with the test organism. The plates were incubated for 24 hours at 37 °C for bacteria and 28 °C for fungi. The zone of inhibition of bacterial and fungi growth around the disc was observed.

The compounds were tested against a liver carcinoma cell line (HEPG2). The method applied is similar to that reported by Skehan et al.⁵³ using 20 Sulfo-Rhodamine-B stain (SRB). Cells were plated in 96-multiwell plate (104 cells/well) for 24 h before treatment with the test compound to allow attachment of cell to the wall of the plate. Different concentrations of the compound under test (0, 1.0, 2.5, 5.0, and 10 μg/ml) were added to the cell monolayer in triplicate wells individual dose, and monolayer cells

were incubated with the compounds for 48 h at 37 °C and in atmosphere of 5% CO₂. After 48 h, cells were fixed, washed and stained with SRB stain, excess stain was washed with acetic acid and attached stain was recovered with Tris-EDTA buffer. Color intensity was measured in an ELISA reader, and the relation between surviving fraction and drug concentration is plotted to get the survival curve of each tumor cell line after the specified compound and the IC₅₀ was calculated.

Acknowledgment

The authors thank Asmaa Atrous for her contribution to this study. We are grateful to the Spanish Government (project CTQ2009-11027/BQU).

Graphical and textual abstract for the contents pages.

Cycloadditions between aryl azides and activated alkenes e.g. coming from β -dicarbonyl compounds were performed; their mechanism and regioselectivity were theoretically studied using DFT methods at the B3LYP/6-31G* level.
