Abstract
Lung barrier protection by Sphingosine-1 Phosphate (S1P) has been demonstrated experimentally, but recent evidence suggests barrier-disruptive properties of high systemic S1P concentrations. The S1P analog FTY720 recently gained an FDA approval for treatment of multiple sclerosis. In case of FTY720 treated patients experiencing multiple organ dysfunction syndrome the drug may accumulate due to liver failure, and the patients may receive ventilator therapy. Whereas low doses of FTY720 enhanced endothelial barrier function, data on effects of increased FTY720 concentrations are lacking. We measured transendothelial resistance (TER) of human umbilical vein endothelial cell (HUVEC) monolayers, performed morphologic analysis and measured apoptosis by TUNEL staining and pro-caspase-3 degradation in HUVECs stimulated with FTY720 (0.01-100 µM). Healthy C57BL/6 mice and mice ventilated with 17ml/kg tidal volume and 100% oxygen for 2 h were treated with 0.1 or 2 mg/kg FTY720 or solvent, and lung permeability, oxygenation and leukocyte counts in BAL and blood were quantified. Further, electron microscopic analysis of lung tissue was performed. We observed barrier protective effects of FTY720 on HUVEC cell layers at concentrations up to 1 µM while higher concentrations induced irreversible barrier breakdown accompanied by induction of apoptosis. Low FTY720 concentrations (0.1 mg/kg) reduced lung permeability in mechanically ventilated mice, but 2 mg/kg FTY720 increased pulmonary vascular permeability in ventilated mice accompanied by endothelial apoptosis, while not affecting permeability in non-ventilated mice. Moreover, hyperoxic mechanical ventilation sensitized the pulmonary vasculature to a barrier disrupting effect of FTY720, resulting in worsening of ventilator induced lung injury. In conclusion, the current data suggest FTY720-induced endothelial barrier dysfunction, which was probably caused by pro-apoptotic effects and enhanced by mechanical ventilation.
Keywords: Ventilator-induced lung injury, FTY720, Vascular permeability, acute lung injury, apoptosis

1. Introduction

Multiple organ dysfunction syndrome accounts for high morbidity and mortality rates and is frequently associated with vascular leakage. In the lung, the loss of vascular barrier integrity evokes pulmonary edema formation, surfactant dysfunction, and impaired lung compliance, resulting in deterioration of pulmonary gas exchange and eventually the requirement of hyperoxic mechanical ventilation (MV). Although being a life saving intervention in acute respiratory failure without an alternative, MV may evoke ventilator-induced lung injury (VILI), which conjointly with hyperoxia further enhances inflammation and lung permeability, thereby aggravating the initial lung injury.

FTY720 [2-amino-2-(2-[4-octylphenyl]ethyl)-1,3-propanediol] is a structural analog of the endogenous sphingolipid Sphingosine-1 Phosphate (S1P). The five known S1P receptors (S1PR1-5) are ligated by FTY720, with relatively low affinity to S1P2 and S1P3. Comparable with S1P, FTY720 has potent immunomodulatory effects by reducing total numbers of circulating lymphocytes via inhibition of T- and B-Cell egress from lymphoid tissues[1]. Thereby, FTY720 prevented acute graft rejection and destruction in animal studies[2] as well as in clinical trials in renal transplant patients[3-5]. Notably, a therapeutic effect of FTY720 for the treatment of multiple sclerosis has been evidenced by clinical trials and FTY720 only recently gained FDA approval (NDA 022527) for the treatment of multiple sclerosis [6-9].

Beside immunomodulatory properties, S1P and FTY720 may impact on the regulation of pulmonary endothelial barrier function[1,10]. Vascular endothelial cells primarily express S1P1, S1P2 and S1P3. In the lungs, physiologic S1P
concentrations (0.5-1 µM) may increase microvascular barrier integrity via ligation of S1P1[10] by promoting actin cytoskeletal regulatory protein recruitment to membrane lipid rafts and Gi-coupled signalling to cytoskeletal elements via Rac GTPase[11-13]. Infusion of S1P or FTY720 reduced lung microvascular leakage in different models of lung injury, including intratracheal Lipopolysaccharide (LPS) application in mice[14], murine and canine ventilator induced lung injury[15], acute necrotizing pancreatitis-associated lung injury in rats[16], and ischemia/reperfusion injury following syngeneic rat lung transplantation[17]. In accordance, Sphingosine-Kinase 1 (SphK1) deficient mice were more susceptible to LPS-induced lung injury as compared to their wild type littermates[18]. Moreover, even a S1P receptor independent increase of endothelial barrier function by FTY720 has been observed in vitro[19]. However, S1P at higher concentration (>5 µM) mediates RhoA dependent barrier disruption through ligation of S1P2 and S1P3, which couple to G\textsubscript{i}, G\textsubscript{q} and G\textsubscript{12/13}[10,20]. Of note, even the selective S1P1 agonist SEW-2871 produced concentration-dependent barrier-regulatory responses in murine lungs, evoking significant alveolar-capillary barrier disruption in higher concentrations[21].

FTY720 has a long half life of approximately 8 days, exclusively employs hepatic metabolism via the cytochrome p450 4F2 (CYP4F2) and has a huge volume of distribution. Thus, accumulation of FTY720 is probable in patients with multiple organ dysfunction syndrome [22-25]. Considering the complex role of S1P receptor signaling in the regulation of endothelial barrier function, relevant risks for critically ill FTY720-treated patients need to be envisioned.

In the current study, we analyzed concentration-dependent effects of FTY720 on endothelial barrier function in vitro and in healthy mice, and investigated the impact of different FTY720 dosing on lung injury evoked by mechanical ventilation and hyperoxia in mice.
2. Methods

2.1. Transcellular Electrical Resistance (TER) of Endothelial Cells

Human umbilical cord vein endothelial cells (HUVEC) were isolated as described[26] and grown on evaporated gold electrodes, connected to an electrical cell-substrate impedance system (Applied Biophysics, Troy, USA NY). Cells were exposed to different concentrations of FTY720 (Cayman, Ann Arbor, USA) ranging from 0.01 to 100 µM and TER values from each microelectrode were continuously monitored and normalized as the ratio of measured resistance to baseline resistance.

2.2. Preparation of human endothelial cells and F-actin staining

HUVEC obtained from collagenase digestion were washed, resuspended, cultivated in MCDB 131-10% FCS and seeded onto 24-well Thermanox slides (Nunc, Germany) [26]. Studies were performed using confluent endothelial cell monolayers in their second passage. HUVEC were incubated with 1 or 100 µM FTY720 for 1 h. Slides were fixed for 20 min in 3% paraformaldehyde. Permeabilization of cell membranes was performed using 1% Triton X100, and F-actin was stained with phalloidin Alexa 488 (Molecular Probes, Invitrogen) as described previously[26]. Slides were analyzed using a Pascal 5 confocal scanning laser microscope (Zeiss, Jena, Germany) equipped with an air-cooled argon laser (Axioskop 2 Mot microscope, Zeiss). Alexa 488 fluorescence was excited with 488 nm argon-ion laser beam and imaged using a NT80/20/488 beam splitter and a 505 nm longpass emission filter.

2.3. TUNEL staining

For the assessment of apoptosis, HUVECs grown on gelatin-coated Thermanox slides were stimulated as indicated, washed twice, and incubated in a humidified
atmosphere. Cells were fixed in paraformaldehyde 4%, washed, and DNA strand breaks were labeled by Fluorescein (FITC)-dUTPnick-endlabeling (TUNEL), and enhanced by application of Alexa 488 anti FITC antibody (1:1,000, 1 h at 37°C) as described previously[27]. F-actin was visualized by marking with Alexa 546-labeled phalloidin (1:200, 30 min). Staurosporin 10µM was used as a positive control for apoptosis. Staurosporin treated cells, in which the enzymatic reaction leading to a positive signal of fluorescence was not performed served as negative controls, confirming the TUNEL signal as specific. Analysis of the slides was performed by using a Zeiss Pascal 5 confocal microscope (objective lens: Plan-Apochromat 63x/1.4) (Zeiss, Jena, Germany).

2.4. Pro Caspase 3 degradation

HUVECs were grown to confluent cell layers and incubated with indicated concentrations of FTY720 or buffer for 1 h. After trypsination, cells were washed and lysed in buffer containing Triton X-100, subjected to SDS-PAGE, and blotted on Hybond-ECL membrane (Amersham Biosciences, Freiburg, Germany). Immunodetection of procaspase 3 was carried out with specific antibody (Upstate Biotechnology, Lake Placid, USA). In all experiments, actin (Santa Cruz Biotechnologies, Santa Cruz, USA) was detected simultaneously to confirm equal protein load. Both proteins were visualized by incubation with secondary IRDye800- or Cy5.5-labeled antibodies (Odyssey infrared imaging system, LI-COR).

2.5. Mice

All procedures were approved by local and governmental (LAGeSo, Berlin) authorities. VILI was induced as described[28]. In summary, female C57BL/6 mice (11-15 weeks; Charles River, Sulzfeld, Germany) were anesthetized by repetitive
intraperitoneal injections of xylazine every 50 min (25 µg/g) and ketamine (125 µg/g). Body temperature was measured continuously using a rectal probe and maintained at 37°C by a heating pad. After tracheotomy and intubation, mice were ventilated (MiniVent, Harvard Apparatus, March, Germany), and airway pressure was raised to 35 cmH₂O for 5 seconds for lung recruitment, followed by ventilation with 7 ml/kg tidal volume (Vₜ), positive endexspiratory pressure (PEEP) = 6 cmH₂O, and inspiratory fraction of oxygen (FiO₂) = 1. A carotid artery catheter was placed for blood pressure monitoring and continuous infusion of sodium chloride 0.9% containing 100 mmol/l HCO₃⁻ at 350 µl/h during the ventilation period. When baseline conditions were established, ventilator settings were changed to 17ml/kg tidal volume and PEEP = 0 cmH₂O. At termination of experiments mice were sacrificed by exsanguination via the carotid artery catheter. Non-ventilated mice did not undergo surgery and were spontaneously breathing (FiO₂=0.21).

Mice were injected with either solvent or 0.1 mg/kg or 1 mg/kg FTY720, dissolved in 0.9% saline, 30 min before preparation. Mice in the high dose group received a second dosage of 1 mg/kg after one hour of ventilation while the other groups received injections of solvent. Non-ventilated mice were injected with same dosages in matched intervals when indicated.

2.6. Measurement of oxygenation

PₐO₂ was quantified in arterial blood of all animals subjected to MV (ABL700, Radiometer-Copenhagen). Oxygenation was expressed as pₐO₂/FI₂ (P/F ratio).

2.6. Lung vascular permeability

Human serum albumin (HSA; 1 mg; Baxter, Unterschleißheim, Germany) was injected via the carotid artery catheter or the tail vein in ventilated or non-ventilated
mice, respectively, 90 min before termination of the experiment. Mice were sacrificed and bronchoalveolar lavage (BAL) was performed with 2x800 µl phosphate buffered saline (PBS). BAL and plasma HSA levels were quantified by ELISA (Bethyl Laboratories, USA). Permeability was assessed by calculating HSA BAL/plasma ratio.

2.8. BAL and blood leukocyte counts

BAL cells were counted by hemocytometer and differentiated by flow cytometry (FACSCalibur, BD, Heidelberg, Germany) analyzing forward and side scatter characteristics and expression of surface antigens CD45, Gr-1 and F4-80. Blood leukocytes were counted and differentiated by flow cytometry analyzing CD45 and Gr-1 surface expression using TruCount tubes (BD, Heidelberg, Germany).

2.9. Electron microscopy

Lungs were flushed via the pulmonary artery, cut, immersion-fixed (1.5% glutaraldehyde, 1.5% paraformaldehyde in 0.15 M HEPES), rinsed (0.1 mmol/l HEPES, 0.1 mmol/l cacodylate buffer) and osmicated (1% osmium tetroxide in 0.1 mmol/l cacodylate buffer). After rinsing in 0.1 mmol/l cacodylate buffer and distilled water, specimens were stained in half-saturated aqueous uranylacetate solution (1:1). Samples were dehydrated in ascending acetone concentrations, embedded in epon, cut (70 nm), stained with lead citrate and uranyl-acetate, and analyzed as described previously[29].

2.8. Statistical analyses

Data are expressed as mean +/- SEM. For comparison between groups Man-Whithey u-test was used. P values <0.05 were considered statistically significant.
3. Results

3.1. FTY720 enhanced or disrupted endothelial cell monolayer integrity, depending on the employed concentration.

Confluent monolayers of human umbilical vein endothelial cells (HUVECs) stimulated with 0.01, 0.1 or 1 µM FTY720 showed a dose-dependent increase in TER, and endothelial barrier function was continuously improved during the observation period of 180 min (Fig. 1a). In contrast, 100 µM FTY720 rapidly impaired endothelial barrier function. Notably, 10 µM FTY720 initially increased TER, which declined below the baseline values during the further observation period. Area under curve (AUC) analysis of TER confirmed this observation (Fig. 1b). Absolute TER values at 60, 90, 120, 180 min revealed increased values when HUVECs were stimulated with 0.01, 0.1 or 1 µM FTY720, whereas 10 and 100 µM FTY720 reduced TER (Fig. 1c) as compared to untreated HUVEC monolayers.

3.2. High FTY720 concentration causes endothelial cell stress and damage

To further analyze the endothelial barrier-increasing effect of low FTY720 concentrations and the barrier-disrupting effects of high concentrations, cell morphology of endothelial cells was evaluated. Taking the results of the TER experiments in account HUVECs were stimulated with 1 or 100 µM FTY720 or solvent for 60 min. HUVECs stimulated with 1 µM FTY720 displayed a morphology indistinguishable from non stimulated HUVECs. Stimulation with 100 µM FTY720 led to severe cell detachment from the endothelial cell layer (Fig. 2a).
3.3. High FTY720 concentration induces apoptosis in endothelial cells

HUVECs were incubated with solvent or 1, 10 or 100 µM FTY720 for 60 min and TUNEL staining was performed to evaluate for apoptosis. In cells stimulated with solvent, 1 or 10 µM FTY720, no TUNEL positive stained cells were detectable while incubation with 100 µM induced apoptosis (Fig 2b). To further enhance evidence of FTY720 induced apoptosis, HUVECs were incubated with 0.1, 10 or 100 µM FTY720 for 60 min, and caspase 3 activation was assessed by analyzing the degradation of procaspase 3 by western blot technique. After 60 min, 100 µM FTY720 induced degradation of procaspase 3, which was not detected after incubation with solvent or 0.1 or 10 µM FTY720, suggesting apoptosis to be one underlying mechanism of FTY720 induced barrier breakdown (Fig. 2c).

3.4. FTY720 treatment did not evoke lung injury in non-ventilated mice

To evaluate the impact of increasing FTY720 dosage on lung permeability in vivo, healthy mice were treated with 0.1 mg/kg or 2 mg/kg FTY720. Pulmonary vascular permeability was quantified, and differential white blood cell count was performed. In healthy mice, FTY720 (0.1 and 2 mg/kg) did not alter lung permeability (Fig. 3a), decreased circulating lymphocytes, and did not affect monocyte and PMN counts (Fig. 3b).

3.5. High dose FTY720 aggravated lung injury in mechanically ventilated mice

MV with 17 ml/kg V_f increased pulmonary permeability in healthy mice, and treatment with 0.1 mg/kg FTY720 significantly attenuated pulmonary permeability provoked by MV. In contrast, mice treated with 2 mg/kg FTY720 developed dramatically increased pulmonary permeability as compared to untreated ventilated
mice (Fig. 4a). FTY720 did not alter mean systemic arterial blood pressure (data not shown).

As permeability edema may impair pulmonary gas exchange, arterial pO$_2$ (p$_a$O$_2$) after 120 min of MV was quantified. Treatment with 2 mg/kg FTY720 impaired gas exchange reflected by a lower p$_a$O$_2$ in this group, as compared to other groups (ctr. 376.8 ± 28.9, 0.1 mg/kg FTY720 393.6 ± 23.63, 2 mg/kg FTY720 342.5 ± 29.86 [mmHg]; mean ±SD) (Fig. 4b). MV evoked accumulation of neutrophils in BAL fluid. Treatment with FTY720 did not alter recruitment of neutrophils to the lung in VILI (Fig. 4c).

3.6. High dose FTY720 induced endothelial apoptosis in VILI

In solvent treated mice, MV evoked edema of the alveolar epithelium, while endothelial injury was observed only sporadically. Non-ventilated mice treated with 0.1 mg/kg FTY720 showed intact endothelium and epithelium. After 2h of MV, mice treated with 0.1 mg/kg FTY720 developed epithelial edema, while endothelial apoptosis was noticed occasionally. Non-ventilated mice subjected to 2 mg/kg FTY720 displayed intact epithelium and overall intact endothelial integrity, while few endothelial cells underwent apoptosis. In contrast, 2h of MV evoked pronounced endothelial injury in mice treated with 2 mg/kg FTY720, as displayed by endothelial disintegrity and frequent endothelial apoptosis. Moreover, epithelial injury was observed in lungs of mechanically ventilated mice after treatment with 2 mg/kg FTY720 (Fig. 5).

4. Discussion

The current study provided evidence that the S1P analog FTY720, which has recently been approved by the FDA as a novel treatment for multiple sclerosis (NDA
and has been evaluated as immunosuppressant following renal transplantation may impair endothelial barrier function due to induction of apoptosis at high concentrations \textit{in vitro}. Moreover, our findings suggested that hyperoxic mechanical ventilation may pave the way for detrimental effects of FTY720 on pulmonary endothelial barrier function by induction of endothelial apoptosis \textit{in vivo}, thereby further impairing pulmonary gas exchange in mice.

Endothelial barrier function is tightly regulated by various mechanisms including S1P-related effector systems, and FTY720 acts as a S1P analog[1,10]. In line with previous observations[19,30], low FTY720 concentrations stabilized endothelial barrier function of HUVEC monolayers in the current investigation. However, it has also been reported that particular structural analogs of FTY720 caused endothelial barrier breakdown, indicating a more complex and concentration-dependent effect of FTY720 on the regulation of vascular integrity[31]. Indeed, FTY720 at high concentrations (10-100µM) seriously impaired endothelial barrier function in the current study. Barrier disruptive properties have been reported for S1P2 dependent signaling pathways[32], but FTY720 has virtually no affinity to S1P2 up to concentrations of 10 µM [33]. Thus, an additional mechanism for barrier breakdown, possibly in synergism with S1P2 ligation at FTY720 concentrations higher than 10µM may underlie the observed impairment of endothelial barrier function. Here we observed that endothelial barrier disruption by high concentrations (100µM) of FTY720 was accompanied by induction of apoptosis suggesting apoptosis to be one possible underlying effect of FTY720 induced barrier dysfunction. These findings are in line with studies reporting induction of caspase 3 dependent apoptosis by FTY720 in different cell types[34,35].

In humans FTY720 has an elimination half life of more than 8 days under 5 mg daily dosing, and a high volume of distribution exceeding 1000 l [22]. Hepatic impairment
and interference with CYP4F2 metabolism, which can be confined by other drugs including ketokonazole, led to reduced FTY720 clearance and increase of systemic FTY720 levels[23-25]. Thus, in critically ill patients who suffer from multiple organ dysfunction and receive complex drug therapy, FTY720 levels may likely exceed the aimed therapeutic tissue concentration. Moreover, it is tempting to speculate that FTY720 and endogenous S1P may have particular additive effects. Importantly, enhanced SphK1 activity was observed in phagocytes of septic patients, and SphK1 inhibition augmented the course of fatal sepsis in mice[36]. Therefore, detrimental effects of enhanced SphK1 activity may possibly be further aggravated by increasing FTY720 tissue concentrations in sepsis with multiple organ dysfunction syndrome.

After discovering a barrier disruptive effect of high FTY720 concentrations in primary human endothelial cells we intended to investigate the impact of different FTY720 doses on endothelial barrier function in vivo, and thus decided to quantify pulmonary vascular leakage in mice. In line with various studies in which mice treated with comparable FTY720 doses did not develop serious side effects[37-39], no impact of FTY720 on pulmonary permeability was observed in healthy mice. Notably, in mice treated with 2 mg/kg FTY720 apoptotic endothelial cells and endothelial barrier disruption were noted by electron microscopic evaluation occasionally, which obviously remained without measurable consequences for overall vascular integrity in healthy mice. However, to model the clinical situation of FTY720 accumulation, use of healthy mice may not be appropriate as accumulation of FTY720 may predominantly occur in critically ill patients. One third of patients in intensive care units are receiving MV[40], frequently with a high fraction of inspiratory oxygen, and increased pulmonary permeability is a hallmark of both ventilator-induced and hyperoxic lung injury[41,42]. Thus, we tested the impact of FTY720 on pulmonary vascular permeability simultaneously affected by MV and hyperoxia. According to
studies evaluating FTY720 in other models of ALI[14,16] we observed that low
dosing (0.1 mg/kg) of FTY720 protected against MV-induced pulmonary
hyperpermeability. In contrast to this observation, but in consistence with our findings
in FTY720 challenged HUVEC monolayers, 2 mg/kg FTY720 evoked a dramatic
increase of pulmonary permeability in VILI. In the 2 mg/kg FTY720 group ventilated
for 2 h, but not in the VILI control group marked endothelial injury and in particular
endothelial apoptosis was detected by electron microscopy. In mice being treated
with 0.1 mg/kg FTY720 and ventilated for two hours, a small proportion of endothelial
cells also revealed signs of damage and apoptosis. These findings suggested that
apoptosis might be one underlying mechanism for endothelial barrier breakdown
observed in ventilated and FTY720-treated mice.

Neutrophil accumulation and activation may also contribute to the development of
lung failure in pulmonary inflammation. Of note, TNFα-induced, integrin mediated
neutrophil recruitment has recently been shown to be SphK1 dependent[43].
However, neutrophil adhesion to TNFα-activated endothelium was independent of
the G-protein coupled S1P receptors[43], and we did not observe increased
neutrophil accumulation in the lungs of ventilated mice after treatment with FTY720.

As 2 mg/kg FTY720 did not increase permeability or evoke significant endothelial
apoptosis in non-ventilated mice, our findings suggested a sensitization of the
pulmonary vasculature by hyperoxia and VILI towards the barrier disrupting effect of
FTY720. Cyclic stretch in VILI as well as hyperoxia may mediate proapoptotic signals
[44]. However, several further mechanisms of the sensitization process may be
proposed in the current context, including increased affinity of S1P2 or S1P3 to
FTY720, and further studies are warranted to elucidate the interplay of hyperoxic VILI
and FTY720.
Some limitations of the current study have to be considered. Mice were ventilated with relatively high tidal volumes and without PEEP, which does not reflect recommended lung protective ventilation. Notably, the observation period in mouse models is usually limited to few hours as compared to ventilation of humans for days or weeks. In the applied model key mechanisms of VILI including pulmonary leukocyte recruitment and increase in lung permeability developed within the observation period, displaying suitability of the model for analysis of FTY720 effects in particular on pulmonary permeability within the limited observation period of 2h. Moreover, according to the baby lung concept of the acute respiratory distress syndrome (ARDS) [45], the forces affecting healthy lungs when being ventilated with 17 ml/kg bodyweight may apply in ventilated areas of inhomogeneously injured ARDS lungs even under lung protective ventilation.

5. Conclusion
The results of this study may have significant impact on the consideration of FTY720 dosing in humans. Different clinical studies analyzed FTY720 pharmacokinetics, pharmacodynamics[22] and the use of FTY720 for the treatment of graft rejection[3,5] or multiple sclerosis[6-9], and adverse effects related to impaired endothelial barrier integrity have not been reported. Notably, in none of these trials critically ill patients receiving MV were included. Although conclusions from in vitro findings and mouse experiments should be drawn carefully with respect to human patients, it is tempting to speculate that in ventilated, critically ill patients a lowered pulmonary toxicity threshold of FTY720 by VILI combined with systemic FTY720 accumulation may aggravate VILI evoked lung permeability. As FTY720 is a promising new drug candidate which gained FDA approval for the treatment of relapsing multiple sclerosis recently and is thus expected to enter clinical practice in
the near future, it may be necessary to consider this possible side effect, to conduct appropriate clinical studies, and to revise optimal dosing of FTY720 for critically ill and mechanically ventilated patients.

9. Figure legends

Fig. 1 Transcellular electrical resistance of FTY720 treated endothelial cell monolayers

HUVECs, grown to confluence on gold microelectrodes to measure transendothelial electrical resistance (TER) were stimulated with FTY720 in concentrations of 0.01, 0.1, 1, 10, 100 µM or with solvent (ctr.). a) One representative experiment is shown. Low dose FTY720 (0.01, 0.1 and 1 µM) enhanced endothelial barrier function, whereas 100 µM FTY720 induced rapid barrier breakdown. 10 µM FTY720 initially enhanced cell layer integrity but evoked barrier breakdown after >60 min of stimulation. b) These observations were confirmed by area under the curve (AUC) analysis. c) Bar graphs depict mean ± sem of TER values at the time points 60, 90, 120, 180 min. (* p<0.05 vs ctr., # p<0.05); (n = 4, triplet or quartets were used in each replication of the experiment)

Fig. 2 High concentrations of FTY720 induced apoptosis in endothelials cells

Confluent HUVECs were incubated with FTY720 (1, 10 or 100 µM as indicated) or solvent for 60min. a) F-actin staining. HUVECs stimulated with 1 µM FTY720 showed no significant changes as compared to control, whereas incubation with 100 µM FTY720 induced disruption of HUVEC monolayers with intercellular gap formation and detachment of cells from glass slides. b) Apoptosis was detected by TUNEL staining in cells stimulated with 100 µM FTY720. Staurosporin (10 µM) was used as positive control for apoptosis. Staurosporin treated cells, in which the enzymatic reaction evoking fluorescence was not performed, confirmed the TUNEL signal specific. c) Apoptosis was induced by 100µM FTY720 as indicated by proapoptase-3 degradation. a-b) representative images of three independent experiments with similar results are shown.
**Fig. 3** FTY720 treatment did not evoke lung injury in non-ventilated mice

Mice were treated with 0.1 mg/kg or 2mg/kg FTY720, or solvent (ctr.). BAL was performed and blood was drawn 2.5 h after the initial dosage, matching the time point of sample collection in the MV experiments. (Fig. 4) a) FTY720 did not alter pulmonary vascular permeability (n = 5). b) Circulating lymphocytes were decreased by FTY720 treatment while neutrophils (PMN) and monocytes were unaffected. (*<0.05, n = 5)

**Fig. 4** FTY720 aggravated lung permeability in mechanically ventilated mice

VILI was induced in mice treated with 0.1 mg/kg or 2 mg/kg FTY720, or solvent (ctr.) by 2h of mechanical ventilation (MV). (NV: non ventilated mice). a) MV evoked pulmonary hyperpermeability. Treatment with 0.1 mg/kg FTY720 reduced permeability while 2 mg/kg FTY720 further increased permeability. (## p<0.01 vs. NV, *p<0.05, **p<0.01; n = 5-6) b) Oxygenation in mice after 2h of MV (*p<0.05; n = 5-6) c) BAL neutrophils (PMN) were quantified. FTY720 did not affect VILI induced neutrophil invasion to the lung. (*p<0.05 vs. NV, n = 5-6).

**Fig. 5** FTY720 induced endothelial damage and apoptosis in mechanically ventilated mice

Non ventilated (NV) and ventilated (MV) mice were treated with 0.1 mg/kg or 2 mg/kg FTY720, or solvent (ctr.). Lungs were analyzed by electron microscopy. a) NV ctr. mice displayed intact endothelium and epithelium. b) Epithelial edema was observed after 2h of MV in ctr. mice while endothelial injury was observed only sporadically. c) Intact endothelial and epithelial integrity in NV mice treated with 0.1 mg/kg FTY720. d) Epithelial edema and occasional endothelial apoptosis after MV and FTY720
treatment (0.1 mg/kg) e) Intact alveolar epithelium and sporadic endothelial apoptosis in lungs of NV mice treated with 2mg/kg FTY720. f) MV in mice treated with 2mg/kg FTY720 resulted in major endothelial injury and endothelial apoptosis in addition to prominent epithelial injury. (AE I = Alveolar epithelial cell type I; AE II = Alveolar epithelial cell type II; E = Endothelium; * = Epithelial swelling; + = Endothelial swelling; NG = Neutrophil Granulocyte; G = Apoptotic Granulocyte; AP.E = Apoptotic Endothelium. Representative images of three independent experiments are shown)
